ALLUSION has already been made in former numbers of THE LANCET to the proposed removal of the bodies from the vaults of St. Mary Woolnoth, Lombard-street, to some extramural burial-ground. A Consistory Court was held by Dr. Tristram on the 4th inst. at St. Paul's Cathedral at which certain final details were settled, while some further additional interesting historical facts were disclosed. It would appear from these that the church was partly burnt in the Great Fire of 1666, and was not rebuilt as it now stands till 1719. Between 1830 and 1832 there had been 139 adults and 23 children's bodies buried, which must all have been deposited in the vaults of the church. This was the time of year most convenient for removing the remains, and Mr. Arnold Statham, the counsel representing the parishes, expressed a hope that the church might be reopened before Christmas. Including the number of interments above mentioned, those of 1681 adults and 422 children had taken place between the years 1700 and 1832, in which latter year the vaults were closed. In consequence of the effluvia from the vaults permeating the church nearly every official of the church (as the rector, the Rev. J. M. S. Brooke, stated) had for years died either directly or indirectly from the effects of the unbearable smell in the church. Dr. Sedgwick Saunders, medical officer of health for the City of London, had reported that the state of the church was unwholesome, and it was closed on Christmas Eve last. The rector added that he had often, while conducting divine service, heard coffins fall one upon the other in the vaults! Many were lead coffins and fell ten or twelve feet! It also appeared that in 1886 the inhabitants contributed between £600 and £700 with the object of hermetically sealing the vaults, and that this, which was the second attempt to effect the same object, was abortive. A sum of £1200 had also been spent in flooring the church above the vaults under the superintendence of the surveyors to the Charity Commissioners, who had contributed the money. Complaint was now made of the hardship of spending an additional sum

of £900, the sum calculated as necessary for the ground alone which would be required in the cemetery to which the remains must be conveyed. Although we sympathise with the parishioners who have been so heavily taxed for the errors of their ancestors, we must, in justice to the cemetery authorities, point out that the ground under their control was acquired and laid out for the remains of a generation subsequent to those in St. Mary's Woolnoth. Some of these, formally interred here, were removed probably in 1830, when part of the churchyard was taken for the formation of King William-street. The remains were those of 300 bodies, which were removed to St. Michael's, Crooked-lane, 568 more which were reinterred in the vaults now to be emptied, and 112 in the "cloisters," the position of which no one now knew. The estimate for the whole work required by the Order in Council was £1955, which would cover the re-interments. In granting the faculty for carrying out the work the Chancellor expressed a hope that the parish might be relieved from at least some of the expense. In conclusion it may be remarked that the attempts to seal up these vaults hermetically, though attempted and repeated at different times, not only failed, but, according to the evidence of Mr. Phillips, the vestry clerk, "had only made matters worse." The ventilating shafts in the walls of the church had been stopped up, and the architects said that they could not be re-opened without danger. This conveys a warning to all in charge of those other City churches the vaults of which contain human remains, and brings into strong contrast the advantages to all concerned of burial in the earth and in perishable coffins.

#### A REVISED PHARMACOPEIA.

AT the inaugural evening meeting in Edinburgh of the Pharmaceutical Society of Great Britain, Professor Charteris, who gave the address, set himself an easy task in selecting for his subject "Suggestions for a Revised Pharmacopœia." He first gave a slight sketch of the history and objects of a Pharmacopœia, and he rendered this portion of his address very entertaining by quoting numerous extracts from a book published in 1691 by "William Salmon, professor of physick at the Blue Balcony, by the Ditch Side, nigh Holborn Bridge," and he noted the curious fact that the diseases all told amounted to fifty-five, while the remedies for these were not less than 4362. Very little reverence for the wisdom and knowledge of our forefathers was shown in the selection of passages for quotation, which, however, served sufficiently well to indicate the gradual progress made in pharmacy during the next hundred years. The evolution of the London, the Edinburgh, and the Dublin Pharmacopœias, and the replacement of these by the British Pharmacopœia, received due notice, and it was announced that it was an open secret that another edition of the last-named would be issued within the next two years. Coming then to the suggestions offered for discussion it was found that these comprised a very lengthy list of suggested deletions—too lengthy, indeed, to be dealt with here in detail. Many of the articles mentioned were classed as "relics of old times," "household remedies," and "rarely used." It is curious to find in this list some substances, such as nitrate of copper, which have only recently been admitted, and others which held an uncertain tenure of office, passing in and out of the Pharmacopœia for no very obvious reasons. On the whole it must be admitted that nearly all in the long list might be deprived of official recognition without crippling our resources, and to the immense relief and joy of the medical student of the future. Coming next to suggested additions Professor Charteris was extremely modest, only a dozen or so being indicated, and some of these were old friends, notably the green iodide of mercury, which disappeared, under protest, from the Pharmacopœia of 1885. Some of the others named were sug-

gested as candidates for admission at that date, hence it is interesting to find their claims once more pressed. The chief amendments proposed were the introduction of an official preparation of hard and soft paraffin, which might be termed paraffinum medium (not a particularly happy name), the alteration of the melting points of carbolic acid and salicylic acid (the latter obviously being intended to ensure greater purity), the raising of the official dose of extractum filiois liquidum, and an alteration in the composition of the unfortunate injectio morphinæ hypodermica, which has so often been assailed. While cordially agreeing with the desire of Professor Charteris that our pharmacopœia should be rendered "less bulky but far more reliable," it is difficult to understand his concluding hope that "it would become, as in former years, the standard authority of scientific accuracy and the pioneer of progress." It would be most curious to learn what pharmacopœia of "former years" received and deserved such unqualified approval.

#### OVERCROWDING ON BOARD TRAINING SHIPS.

IT would be a matter for general regret if by any fault of administration the good service done for education by means of training ships were seriously interfered with. That such is the case there is nevertheless good reason to believe. It is reported at all events that overcrowding prevails on board these vessels to a marked extent. Lord Spencer, we are pleased to learn, has been duly apprised of this fact, and is taking steps to meet the difficulty arising therefrom. His remedy, which consists in drafting the boys as rapidly as possible out of the harbour ships, is no doubt well considered. The only needful proviso is that this work be carried out with sufficient energy. In view of the great pressure occasioned by want of accommodation, however, it appears likely that some increase in the number of available training ships will also be called for. The unusually high death-rate lately reported on board these vessels is in itself a suggestive circumstance, especially when taken in connexion with the fact of overcrowding and the ordinary prevalence of infectious disorders in early life. In such a case it were true economy rather to exceed than to fall short in providing air space, for nothing is more costly than illness.

#### THE WORKING OF THE FOOD AND DRUGS ACT.

DESPITE the fact that the proportion of adulterated samples during the year 1891 is rather more than 12 per cent. of those examined, and that this result is admitted to be a slight retrogression from the favourable returns of the three previous years, many of the authorities to whom the practical working of the Act is entrusted, and to whom therefore the public look for protection against fraud, have exhibited an unexplained torpidity in the matter. The very existence of the Act, indeed, was absolutely ignored in one metropolitan district (St. Martin's-in-the-fields), in four administrative counties (Hereford, West Suffolk, Montgomery and Radnor), and in twenty-seven boroughs, including many of considerable population, such as Great Yarmouth, West Bromwich, Bury, Tynemouth, Devonport, Southport, and Rotherham, not a single sample having been examined during the whole year in these districts. We have repeatedly urged that the Act runs considerable chance of being reduced to a dead letter simply on account of the lethargy of the local authorities. Surely it cannot be supposed, seeing that 12 per cent. of the total number of samples analysed were adulterated, that St. Martin's-in-the-fields and the other populous districts above enumerated are entirely free from the art and practice of falsification. Only a year ago we had occasion to purchase various samples in one of the very districts mentioned, and the results of our examination gave very little support to the notion that adulteration was a thing of the past.<sup>1</sup> In view of these facts we

insisted that the local authorities should be roused to a stronger sense of their duty, which should consist in the exercise of powers conferred upon them, and in keeping the machinery constantly moving by which the public ought to be protected from fraud, and it may even be, from dangers to health. The recent report of the Local Government Board, from which we derive our information, gives evidence of the efficient manner, as if by contrast, in which public analysts are doing their work, for it is believed that the progress of analytical science has more than kept pace with that of fraudulent sophistication. Farther on the Bluebook contains some interesting remarks (which we emphatically endorse) on the adulteration of milk: "The proportion of added water is often considerable, but it must be remembered that an addition of even 10 per cent., which is probably less than the average, enables the dishonest milkman to keep ten cows instead of eleven." Again, we read: "There is considerable difference in the practice of analysts as regards their reports. One pronounces as adulterated all milk to which he believes water has been added, however small the proportion, while another only condemns samples in which the dilution has been so great that the case may be taken safely into court." We fully discussed in an article in last week's issue of THE LANCET the desirability of fixing a definite standard which should be adopted by every analyst. At present the Act fixes no such standard, and the analyst is bound to adopt a standard of his own based on his own experience and judgment. There are many other items of interest in the report, a digest of which appears on page 1190 of our present issue, but the main facts relating to the Food and Drugs Act are clearly of especial and grave concern to the community. Now that the Local Government Board have expressed surprise "that the local authorities in many cases are content to leave the inhabitants without that protection against fraud by the sale of adulterated food, which the exercise of the statutory powers conferred on the authority would be likely to ensure," we may surely hope the matter will at once be represented to our legislators so that strong pressure may be brought to bear upon the authorities who are concerned.

#### THE BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

WE learn from a full report given in the *Oldham Standard* that at a meeting of the Oldham Medical Society, held on Nov. 11th, the claims of the British Institute of Preventive Medicine received very favourable consideration at the hands of the members of that Society. The Mayor of Oldham (Alderman Noton) was present, and Dr. Corns was in the chair. For some time past the committee entrusted with the promotion of this Institute have been gathering subscriptions, maturing their plans, and preparing their work in London, but it has been left to the Oldham Medical Society to open the campaign in the provinces. The objects aimed at by those responsible for the direction of affairs in connexion with the Institute were set forth by the chairman, Dr. Ruffer, the secretary of the Institute, Dr. Niven, Medical Officer of Health for the Borough of Oldham (who moved the resolution that the medical men of Oldham heartily approve of the establishment of this Institute of Preventive Medicine, and intend to use all means in their power to further its success, and, speaking to his resolution, maintained that it was certainly not creditable to a country like this that, although so many contributions had been so recently made to preventive medicine both by France and Germany, we had contributed so little to this great advance); Mr. Fawcitt of Oldham, Dr. Dreschfeld of Manchester, the Mayor, and Mr. Platt of Oldham, all of whom spoke strongly in favour of the scheme, and asked for the moral support of the medical men of Oldham, which would mean material assistance from many of their patients and

<sup>1</sup> Vide THE LANCET, Aug. 1st, 1891.

friends. There can be no doubt that in this matter Oldham has set an example which, with very great advantage, might be followed by many other of our large and populous centres in the provinces. With the amount of money that is asked for (£60,000) it will not be possible to do everything, but a good building may be raised, and for the performance of work within certain well-defined limits a complete apparatus and staff may be gathered together, with the aid of which much valuable work may be done; and these may be so organised that at any future time, when the enormous advantages to the profession and public have been properly appreciated, additions may be made. Nearly £50 was at once promised by the medical practitioners who were present, and there can be little doubt that other subscriptions will follow in due course. The profession in Oldham will in future be able to point to the fact that its members were the first to take up this matter outside London, but it still remains open to the medical societies of other towns to be able to say that they immediately followed so worthy an example.

#### THE POSTMAN'S KNOCK.

IN THE LANCET of last week we discussed the inconvenience arising in the case of sick persons and others from the frequently startling summons which announces the arrival of the daily post. We referred likewise to various palliatives which might be employed to combat this form of assault upon the nervous system. We did not, however, forget that the true cause of disturbance, the postman himself, continued to flourish in spite of the remedies proposed. Some, perhaps, would have us advise in his case, or at all events as regards his office, the radical treatment of extirpation. We confess that we cannot see our way to counsel a proceeding so formidable. The operation required would be much too great a one to be undertaken without full consultation with many other persons equally interested with ourselves. The widespread paralysis of our ordinary means of communication which it entails moreover would not in our opinion be justified by any sensible relief which might follow the operation. Speaking candidly, therefore, we can see no prospect for those who fear the postal summons but such means of palliation as have already been suggested.

#### THE RETIREMENT OF DR. BRIDGES.

DR. BRIDGES bade farewell to the Metropolitan Asylums Board at their last meeting, and received a warm compliment from Sir Edwin Galsworthy for the tact and ability which he had displayed in his official relations with the Board, the chairman's remarks having the cordial assent of all the members present. Very few people understand precisely where the responsibilities of the Local Government Board begin and end as regards the Metropolitan Asylums Board. Dr. Bridges' position, as representing Whitehall in connexion with the doings of the Asylums Managers, must have been a difficult one. His action has always been marked by courtesy and by a desire to support them, and the Asylums Board may well regret that he now relinquishes his official post. In his farewell address Dr. Bridges especially reviewed the history of the Board's system of small-pox isolation. This is typical of the difficulties attaching to Dr. Bridges' post. He has been understood always to have supported the Asylums Board against the view of an aerial diffusion of the infection from their hospitals, but the public view was strong in the other direction, and the small-pox patients had to be removed far away from London, under a new system which Dr. Bridges declares to have elicited the admiration of the civilised world. He frankly admits that errors may have arisen during the building up of the work of the greatest isolation authority the world has ever possessed. Errors must occur in such a work, but if they are remedied when pointed out by experi-

ence none can well complain. We heartily wish Dr. Bridges much of that cultured enjoyment in his retirement for which he is so well fitted, and as regards the Metropolitan Asylums Board we trust that the Government may find an equally intellectual, skilled and courteous medical inspector to take his place.

#### THE SPREAD OF SMALL-POX.

SMALL-POX continues to spread. Glasgow has some twenty-four cases; and amongst other newly infected places are Burton, Tibshelf in the Mansfield rural district, Melton, where the disease has got into the workhouse, Hipperholme, Lightcliffe, Lymm, Rushden and Enderby, near Leicester, where a case occurred in a common lodging house. At Otley considerable alarm prevails and vaccination is proceeding rapidly. A temporary hospital is also in course of erection. Isolated attacks have also been heard of from other localities. At Warrington there are signs that the epidemic has reached its maximum. Leicester has been visited by Dr. Sidney Coupland on behalf of the Royal Commission on Vaccination. The results of his enquiry are, of course, not known; but they may be taken to include an account of the failure of the much vaunted quarantine system on almost the first occasion when that scheme has been put to any semblance of a real test.

#### IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE autumnal general meeting of this Association took place at 11, Chandos-street, on Nov. 2nd, Director-General Dick, C.B., R.N. (the President), in the chair. The following resolution was passed: "That this meeting regards with satisfaction the recommendation of the Select Committee of the House of Lords to the effect that the governing bodies of the metropolitan hospitals should consider the advisability of opening their honorary staff appointments to other diplomates than those to whom they are at present restricted." On the motion of Dr. Gilbert-Smith it was decided to approach the medical staffs of the various hospitals and to urge upon them to withdraw the invidious restriction by which in many cases the diplomates of the Irish and the Scotch colleges are deprived of equal privileges with their English brethren in this respect. At the dinner which took place the same evening the chair was occupied by the President, Director-General Dick. The Association guest was Admiral Sir R. Vesey Hamilton, K.C.B., and about forty members and guests attended. A letter expressing his regret at not being able to be present was read from Sir Walter Foster, M.P., the first President of the Association.

#### ACCIDENTS DUE TO COVERED VANS.

A DANGER which appears to be almost inevitably associated with the use of covered vans has on more than one occasion received attention in the press. It has been once more illustrated by an accident which occurred a few days ago in Battersea Park-road and which cost a child his life. In this instance the driver in turning his horse did not notice a little boy standing near, and the latter was consequently knocked down and run over. Several persons present gave evidence exonerating the driver from all blame in the matter, the unfortunate occurrence being almost a natural consequence of the child's position at the time. We have nothing to say against the verdict given at the subsequent inquest, which agreed with their testimony. In a sense it certainly was satisfactory, though by no means reassuring. It did not quite satisfy the presiding coroner, however, and his objection to vans from which the carmen could barely see in front of them will be generally appreciated. This leads us to consider how best such accidents may be prevented. Parents can hardly be expected to keep young

children entirely off the streets, nor for that matter are children alone liable to be run over in this way. The van-cover is the real cause of offence. It cannot, we fear, be altogether dispensed with, but surely some arrangement is possible which, by rendering it more open at the sides, would allow the driver a view of at least part of the front wheels of his vehicle, and thus tend to obviate the dangers which must accompany his present ignorance of surrounding conditions.

#### THE HEALTH OF THE PRINCE OF WALES.

IN reference to the rumours concerning the health of His Royal Highness the Prince of Wales, we are informed on trustworthy authority that there is no foundation for them. We understand from our enquiries that His Royal Highness is in the enjoyment of his usual health.

#### ENTERIC FEVER IN LIVERPOOL.

CONSIDERABLE alarm is being felt in Liverpool on account of a large number of attacks of enteric fever amongst business people having their daily occupation in some of the central parts of the city. It is said that in the case of members of one cricket club no less than fifteen Liverpool men of business are down with the disease, and the cause is believed to be the highly insanitary condition of many of the older business premises.

#### PROMPT ATTENDANCE AT HOSPITALS.

A CORRESPONDENT of an evening contemporary complains of delay in a case of serious injury to the foot admitted to one of the general hospitals. Three hours, it is alleged, were allowed to elapse before telegraphing to the surgeon for the day. He was not at home, and two hours more are stated to have elapsed before a surgeon could be procured. A little management would easily prevent such a complaint, if, indeed, it be founded on fact, and clearly strict rules should be made and enforced to secure a prompt attendance of the surgeon for the day, and, failing him, of a substitute, who should be named.

#### MIDWIVES AND CERTIFICATES OF DEATHS.

THE Derby Borough Coroner had a case before him in which a midwife is said to have attended a child five days old with convulsions and congestion of the lungs, and to have discouraged the parents from sending for a medical man till the last moment, when one was sent for, but only to find the child dead. One witness stated that in the event of the child dying the midwife said, "even if it does it will be all right—I can bury it." This was denied by the midwife, who however admitted that something had been said about the case of stillborn children requiring a certificate. The coroner said a lot of that sort of thing had been going on lately in the town and he was determined to have it thoroughly gone into. The determination is a right one and comes none too soon. The coroner adjourned the inquest until November 24th.

#### INFRINGEMENT OF THE PHARMACY ACT.

THE county court judge of St. Helen's, when he recently imposed a penalty of £5 and costs upon a child of fourteen years of age who was proved to have infringed the Pharmacy Act by selling a bottle of oxalic acid, gave effect in the only way that was open to him to the provisions of that statute; but the case is one that brings to light a serious flaw in the Act of Parliament. The child had been left in charge of a chemist's shop during the absence of the chemist and his qualified assistant. A customer called and bought a bottle of the poison at this particular time, with which he shortly afterwards committed suicide. The child appears to

have acted with great intelligence, the customer was asked for his name and warned that the acid was a poison. An adult assistant could not have prevented what subsequently happened. Still there can be no question about the impropriety of permitting children to act in matters of this kind and we should make no complaint if the penal consequences of such a dangerous irregularity had been visited upon the person in authority whose business it was to know the law and his duty to see that in his own establishment it was carried out. It is probable that the child although precocious could not pay the penalty, and we hope that it would in the end fall upon the person morally responsible for the infringement of the Act. That this child should be in the circumstances the person legally responsible is a striking and very unpleasant illustration of the fact that our English law does sometimes deal out very random justice.

#### PREVALENCE OF SCARLET FEVER.

SCARLET FEVER seems just now to be displaying its autumnal increase in various parts of the country in such a manner as to excite some public attention. We hear of schools being closed by sanitary authorities at the instance of their respective officers of health, as at Bedlington and Wirsborth. Scarlet fever is also reported to be prevailing in the Wandsworth workhouse and at Calverley, near Leeds. Between 2000 and 3000 cases a week are being notified throughout the country, of which the metropolis contributes more than a third. The chief other contributory places are Plymouth, Leicester, Liverpool, West Ham and Bradford.

#### "THE TIMES" AND QUARANTINE.

THE special correspondent of *The Times*, whose second article on English Ports and Cholera we discussed last week in reference to quarantine, now states that he is "entirely opposed to" that system. We are glad to have elicited an opinion so definite and so difficult to gather from the article itself. But since he is thus in entire agreement with us as to the opposition to quarantine we hardly understand the purport of his remark as to those "who differ" from him, a remark which might at first sight appear to apply to THE LANCET. On the important point of putting ships from infected ports at short distances on the same footing as ships actually infected, we shall be quite prepared to abide by the results of any attempt to apply such a practice to those of our south-eastern and southern ports which are in daily, rapid and incessant communication with ports of France, Belgium and Holland, for the purposes of an almost uninterrupted stream of passenger and goods traffic. But for the sake of the ports alone, we trust the experiment may never be made.

#### THE CORONERSHIP FOR THE WREXHAM DIVISION OF DENBIGH.

WE regret to have to announce the election of a legal coroner for the Wrexham Division of Denbigh instead of Dr. Edward Davies of Wrexham, who has been acting as deputy coroner for some months past both before and after the death of the late coroner, Mr. Thelwall. He, although a solicitor, was magnanimous enough to appoint Dr. Davies as his deputy, knowing well that he himself could not hold the office of coroner much longer and that Dr. Davies would be a candidate for the vacant office. One of the chief reasons for the election of Dr. Davies's opponent would appear to be that he had a more thorough knowledge of the Welsh language; but, as we understand that the majority of jurors and witnesses understand English and interpreters are rarely required, we fail to see how this can be urged as any reason, seeing that Dr. Davies must have had, by his long residence and extensive practice, a sufficient knowledge of Welsh to enable him to fulfil the

duties of coroner as well as he has done those of deputy coroner. Moreover, it is distinctly undesirable that a coroner should himself act in the double capacity of coroner and interpreter. A coroner makes a declaration to do his duties as coroner, not as interpreter, the latter being sworn to interpret between him and the witnesses. Dr. Davies may be congratulated on having made a good fight and on having been supported by the most influential of the County Councillors.

#### THE LONDON CAB HORSE.

A CONFERENCE is to be held at St. James's Hall on Monday next with the object of improving the condition of the London cab horse in respect of stabling and housing. Medical practitioners have frequent occasion to make use of the services of that willing slave the cab horse, and may be glad to assist so praiseworthy an undertaking.

#### MEDICAL REGISTRATION.

WE would urge on our readers the importance of taking careful note of the intimation issued, according to annual custom, by the Medical Registrar, which will be found in our advertisement columns this week. Inattention to the requirement to forward to any of the respective branch registrars a change of address, or to answer at once any letter of inquiry that may be sent in respect thereof, will subject a registered practitioner to the loss and inconvenience attending the removal of his name from the Medical Register.

#### DIPHTHERIA AND BOARD SCHOOLS.

WE understand there is still some difference of opinion between the Vestry of Islington and the School Board as to the prevalence of diphtheria in the Yerbury Schools and the causes of such prevalence. It is not unlikely that this difference may have to be discussed in a court of law. It would have been much more satisfactory if the medical officers of the respective authorities could have come to some mutual agreement with regard to measures for placing the schools above suspicion, which at present is certainly not their case, even if they be not the *fons et origo* of the diphtheria of the pupils.

#### HAIR SPLITTING.

It is universally admitted that "hair splitting," in its metaphorical sense, is a waste of time and pains, but it may not be altogether superfluous to discuss briefly the causes and treatment, so far as is known, of the actual splitting of the hair, of the scalp and face. It is simply one of several signs which may be exhibited by hair whose nutrition is damaged by either local or general causes. Healthy hair has a gloss upon it due to its lubricating gland, a definite "set," and a remarkable elasticity, so that, if bent at ever so acute an angle, it straightens itself at once when relieved from pressure. But let any interference with its nutrition occur, whether from general constitutional conditions such as syphilis, diabetes, phthisis, fevers &c., or from local causes injuring the hair papilla, as may be seen in alopecia areata, or from the invasion of an organism, as in ringworm, or if the function of the sebaceous gland is interfered with, as in seborrhœa and many inflammatory diseases of the scalp—then some or all of the qualities which we unconsciously value in our hair are lost. It no longer preserves its natural direction or "set" and becomes difficult to keep in order, the hair shaft is dry and lustreless, becomes finer and splits and breaks in ways which vary with the individual as well as from the cause being various. In some people, the hair becomes so dry and brittle that it breaks with the ordinary manipulations of the toilet, a condition known as "fragilitas crinium"; in others the shaft is a little tougher and a green-stick fracture results, the hair not breaking quite across, but the component fibres splitting away, and an appearance

is produced which has been compared to two besoms stuck together and is technically known as "trichorrhæxis nodosa." Far more common than this splitting of the shaft, whether at its surface or in its substance, is "end splitting," in which the hair divides at its extremity into three or four segments, which extend from about a quarter of an inch to an inch down the shaft. This often occurs in very long hair, as in that of women on the head or in men with long, untrimmed beards, and is then explained by the hair being insufficiently nourished owing to its great distance from the roots. This at most only accounts for a moderate proportion of cases, and clipping is the obvious cure. In many cases, however, the cause is situated at the root end, where there may be folliculitis, or some one of the causes, local or general, of which examples have been given. In some persons whose hair is by no means long, especially as regards the hairy portion of the face, the splitting may extend completely down to the root and sometimes apparently starts from there, so that unless closely examined it would appear as if several hairs came from one root. Careful investigation into the cause of the defective nutrition is obviously necessary before rational treatment can be prescribed. This is sometimes easy, as when the patient has recently passed through a severe illness, trouble or anxiety, or has some discernible local affection of the skin; or it may be very difficult, such comparatively scantily nourished structures as the hair and nails even at their best, being often more subtle detectors of some departure from health than our coarser physical methods of investigation can possibly be. Still other corroborative indications of defective health may be discoverable either in the patient or his surroundings, and while these must be met according to circumstances, some help from local treatment may be afforded in many cases. Frequent clipping for long hair has been already alluded to, but does not afford much encouragement when the hair is already short. Nor can good be anticipated from the hair-dresser's usual recommendation of "singeing" after cutting, "to seal up the tubes," as he usually phrases it, thus displaying not only his ignorance of the solid structure of the hair, but also of the physical law which, even if it were a tube, would not allow fluid to escape from it. Such local remedies are calculated to be of service as will increase the blood-supply to the skin, and therefore to the insufficiently nourished papilla, shaving being one such means. We need not, however, now discuss details, but would merely point out the *rationale* of these conditions of hair-splitting and the principles of the treatment which are required to obviate them.

#### EXECUTION OF NEILL, THE SOUTH LONDON MURDERER.

THE execution of the poisoner Neill on the morning of Tuesday last brought with it an almost demonstrable feeling of relief to the mind of the community. His disposition appears early to have manifested a strongly criminal bias, which his after career bore out with a hideous and diabolical completeness in action. The whole history is too familiar to newspaper readers to warrant repetition in our pages. The sentence of death was passed upon him by Mr. Justice Hawkins after trial at the Central Criminal Court. In response to representations made by his solicitors to the effect that evidence tending to prove the culprit's insanity was on its way from America, a respite was granted for a week. It would appear, however, that sufficiently strong evidence to warrant any alteration in the original sentence was not forthcoming. The responsibility thrown upon the Home Secretary in this matter by the provisions of the Criminal Lunatics Act of 1884 is assuredly no light one. We are confident that the public are satisfied with Mr. Asquith's ultimate decision that there were no real grounds for interfering with the death penalty in Neill's case. There

are, no doubt, psychological points and difficulties in the case which only Neill himself could explain or give data upon which an explanation could be based. But, on the far-reaching platform where sanity stretches away into insanity, and in the analysis of human conduct in individual cases, the institutes of law and the institutes of medicine, where they are thus closely brought into relation, cannot afford and cannot dare to be too curious as to the enigmas of psychology in circumstances where the obligations of social life and the personal safety of the members of the community are under consideration.

#### MEASLES AND SCHOOL CLOSURE.

MEASLES is rife just now in many parts of the country, as at Motherwell in Scotland and Tipton in Staffordshire. The absentees from school at the former place number 27 per cent. of the scholars, at the latter about 50 per cent. In face of this, the question of closing the schools at Dalziel has been adjourned for a week by the Motherwell authorities; whilst at Tipton nothing has been done beyond characterising the report of the school attendance officer as "exaggerated." School authorities seem to be still slow to learn that it is the wisest plan to allow their schools to be closed in the early beginnings of an epidemic, before widespread prevalence has rendered their tardy acquiescence in closure a futile and nugatory step.

#### BACTERIOLOGY OF TROPICAL FEVERS.

A PAPER treating on the above subject by Dr. Domingos Freire appears in the *Gazette Médicale de Paris* of Oct. 15th. He states that clinicians have long since established the main differences between the symptoms of the so-called bilious fever and of yellow fever. The object of the paper is to show that bacteriology supports the theory which has been arrived at clinically, and that the causal agent of bilious fever is quite different from that of yellow fever. Observations were made on the blood, bile, urine &c. of living patients and on the viscera after death. Cultivations were prepared on gelatine and agar-agar. Colonies were observed to form within twenty-four hours. They first appeared as a whitish streak along the course of the needle. Large gaseous bullæ then formed on the surface of the nutrient medium. The colonies were scattered in small white patches all over the surface of the agar-agar. Successful cultures were obtained from all the organs, the urine, blood taken from the heart one hour after death, and also from the arm of a patient who had been dead for six days. Similar observations made on yellow fever gave very different results. Colonies developed in the form of a nail, the head of which was on the surface of the cultivating medium, whilst the point penetrated its substance. Gaseous bullæ never formed along the track of the needle. The part forming the head of the nail was perfectly white and was never seen surrounded by smaller colonies. Microscopic examination also revealed radical differences in the microbes of the two diseases. In the case of bilious fever a bacillus was found measuring about nine micro-millimetres in length and three in width. The bacillus was immobile, but was frequently accompanied by numerous mobile spores; it stained well with methyl violet. Each bacillus was divided into segments of different lengths; the segmentation was very rapid. Spores were found at the termination of each segment. In yellow fever, on the other hand, the microbe was a micrococcus and not a bacillus; it was circular in shape, highly refracting, and stained readily with fuchsine and methyl blue. When inoculated into animals in a virulent condition all the symptoms of yellow fever were produced. Inoculation of the bacillus of bilious fever produced in guinea-pigs a fever remittent in type. Post-mortem examinations made on the animals experimented on showed a considerable enlarge-

ment of the spleen, and the gall-bladder was distended with bile. In the stomach a large quantity of dark-green bile was found. The kidneys and lungs were hyperæmic, the heart was arrested in diastole and the auricles were full of dark blood. Blood taken from the heart of the animal and placed on agar-agar produced characteristic colonies. Four tubes inoculated with the bile gave positive results in three cases, the colonies and bacilli presenting the appearances already described. Microscopical examination of sections of the liver and kidney also showed the micro-organisms. In conclusion, Dr. Freire maintains that the bilious fever of hot countries and yellow fever, although closely resembling each other, are perfectly distinct diseases, and that this may be demonstrated both by the clinical features and by their bacteriological characters.

#### DIPHTHERIA PREVALENCE.

IT is reported that diphtheria is prevalent in the Lizard district of Cornwall, where it is ascribed to milk and connected with the consumption by cows of sewage-polluted material. This raises an interesting etiological question which should be followed up. In the meantime some 400 cases of diphtheria are being reported each week throughout England and Wales. London contributes about one-half of them; whilst Oxford, Birmingham and Cardiff are other places in which the disease has shown itself to be abnormally prevalent.

#### ABERDEEN UNIVERSITY CLUB DINNER.

THE biennial dinner of this London club was held on Wednesday evening at the Holborn Restaurant, under the presidency of Dr. Ferrier, F.R.S., who was supported by a large muster of the members. The guests included Sir James Sivewright, K.C.M.G., a distinguished alumnus of the University; Surgeon-General Cunningham, Dr. Lauder Brunton, and others well known in official and social circles. A pleasant evening was passed and a hearty response was given to the toast of the evening, which was proposed in an excellent speech by the chairman, who referred to the approaching completion of the fourth century since the foundation of King's College, Aberdeen, and to the great extension of the University buildings that is now attracting the attention as well as the money of all who are interested in the welfare of the "Granite City." Several Scotch songs were sung with excellent effect during the evening by Mr. Sinclair Dunn.

#### THE INTERNAL ADMINISTRATION OF OZONE IN THE TREATMENT OF PHTHISIS.

DR. HENRY S. NORRIS, in the *New York Medical Journal*, calls attention to the use of ozone in cases of pulmonary phthisis. The preparation of ozone he has used with successful results is called "aquozone," which is a 2½ volume per cent. solution of ozone in water, the stability of which is maintained by the presence of a certain amount of hypophosphites. The remedy was always given in the same way—viz., twelve ounces of aquozone daily in four doses, one before each meal, and the fourth at bedtime, and an ounce and a half of ozonised oil, being half an ounce after each meal. The cases in which it has proved most successful have been in persons under thirty-five years of age with catarrhal phthisis, or where the disease has not passed far into the second stage, has not been too active, and has been limited to a single lobe, or, if in both lungs, has been confined to comparatively small areas. In every case where these conditions existed the improvement has been immediate and progressive. In seven of the fifteen cases reported marked improvement took place: increase in weight, diminution and even cessation of cough and expectoration, termination of night sweats, and, finally, notable and favourable modifications of the physical signs, amounting in two cases to their entire disappearance. Of this last group all

had catarrhal phthisis. In one instance there was consolidation of a part of the upper lobe of each lung; in one case there was a cavity, and in the rest the disease was limited to one lobe. Dr. Norris remarks that if the plan outlined in his series of experiments could be carried still further—if in addition to less crowding and better food for our patients we could keep them in an atmosphere containing a certain and constant amount of ozone (the quantity to be determined by experiment),—might we not hope for better results than are now attained in ordinary hospital practice?

#### INFLUENZA AT GREENWICH.

INFLUENZA is said to be prevailing at Greenwich, and the health officer has reported that already one death has occurred from the disease.

#### ARTIFICIAL DENTURES.

THE opening meeting of the winter session of the Odontological Society, held last week, was devoted to a paper by Mr. Storer Bennett on "Some Methods of Attaching Artificial Dentures," in which he described and illustrated some most ingenious contrivances. It often happens where clasps have to be resorted to that the inclination of the natural teeth is such that the space between them which it is desired to fill up is larger at the gum surface than that on a level with the articulating surface, either from the teeth having fallen towards each other from want of support or from a natural constricted shape of their necks. In both cases where an ordinary denture is fitted with gold clasps there remains on each side of the mineral teeth a space shaped like a bisected isosceles triangle, which is a potent food trap, and, moreover, the natural teeth, by the methods generally in vogue, have to be attached high up near the cutting edges, being both conspicuous and insecure. Gold clasps have but a small degree of elasticity and are in such cases incapable of being made to grasp, when *in situ*, the most constricted part of the teeth. Mr. Storer Bennett, amongst others, has made numerous experiments with various metals which do not corrode in the mouth—for instance, steel springs nickel-plated, diverse combinations of steel and nickel, and aluminium alloys—but without satisfactory results. This led him to experiment with hinged clasps, the subject of the paper. These clasps are of two forms—first, self-adjusting, consisting of a spiral spring of 12-carat gold, contained in a tube closed at one end by a small nut and impinging at the other end of the tube upon the short end of a lever, which is the clasp itself. The other is a spring clasp known to jewellers as a brooch-joint, which requires shutting by means of the finger. Objections were raised at the meeting on the score of complexity, difficulty of cleansing, and the mechanical irritation of the tongue from the prominence of the joint; but most of these seem capable of being overcome, and the use of this method in certain cases should be of great value. Mr. Storer Bennett also showed an artificial tooth (an incisor) with a brooch-joint clasping it firmly in place, which, as the president remarked, was the first time he had heard of a hinged tooth in man.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Freiburg (Baden).*—Professor Ziegler is resigning his post as Extraordinary Professor of Zoology in the Philosophical Faculty for a Professorship of the same subject in the Karlsruhe Technological College.

*Marburg.*—Dr. Arthur Barth has been recognised as *privat-docent* in Surgery.

*St. Petersburg (Military Medical Academy).*—The second Professorship of Operative Surgery and Topographical Anatomy has been filled up by the appointment of Dr. A. I.

Jakobson, Consulting Surgeon to the Duchess of Edinburgh's Hospital.

*Vienna.*—During Professor Kahler's illness Dr. Kraus is taking charge of his medical clinic. Professor Ludwig has been made a life member of the Austrian Upper House.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Jacob Bischoff, Professor of Midwifery and Gynecology in the University of Basle. Previously to his appointment in 1868 as Extraordinary Professor the instruction in gynecology was limited to lectures. By his exertions, however, a department of the Bürger hospital containing twenty-two beds was given into his charge for a gynecological clinic, and from this small beginning a large and important department has grown.—Dr. de Beauclair of Diez.—Dr. Grimmel of Idstein.—Dr. d'Orsonnens, Professor of Midwifery in the Laval University, or Succursale, Montreal.

THE restrictions imposed on marine traffic by the Italian Government, and embodied in the ordinances of Aug. 31st and Oct. 14th, have just been abrogated. Those that remain in force are limited to medical visitations and to disinfections of soiled articles of wearing apparel belonging to arrivals from the French, Belgian and Dutch ports; as also from the German North Sea ports, including Hamburg; from the Russian ports of the Baltic, and the Austro-Hungarian ports. The visitations and disinfections in question are to be practised in the first Italian port at which these arrivals touch.

THE annual dinner of the staff and past and present students of the Dental Hospital of London will be held on Saturday, Dec. 3rd, at the Café Royal, Regent-street, under the presidency of Sir Richard Quain, Bart., M.D., F.R.S., LL.D. Gentlemen either now or formerly connected with the hospital or medical school who may, through inadvertence, not have received special notice, and who desire to be present, are requested to communicate with the Dean at the Dental Hospital, 40, Leicester-square.

WE believe that the testimonial to be presented to Professor James Moleschott of the Roman University on the celebration of his jubilee on Dec. 16th next will take the form of a bust in bronze, to be placed among the Patres Conscripti of medical science, whose sculptured presence still animates the young aspirants to professional honours in the halls of the Sapienza.

THE Alvarenga Prize for 1892 has been awarded to Dr. R. H. L. Bibb, of Saltillo, Mexico, for his essay entitled "Observations on the Nature of Leprosy." The next award will be made on July 14th, 1893. These prizes, of \$180, are awarded by the College of Physicians of Philadelphia for the best unpublished essay upon any subject in medicine.

MR. H. G. HOWSE, M.B., M.S., F.R.C.S., Lecturer on Surgery at Guy's Hospital, and Mr. A. W. Bennett, B.Sc., F.L.S., Lecturer on Botany at St. Thomas's Hospital, are announced as candidates for the vacancy on the Senate of the University of London. Both gentlemen are old-standing members of the Annual Committee.

THE Metropolitan Police Surgeons' Association will hold their annual dinner at the Criterion, Piccadilly, on Thursday, Nov. 24th, at 7 P.M. Mr. A. O. MacKellar, F.R.C.S., chief surgeon, will preside.

THE Public Health and Housing Committee of the London County Council have recommended the appointment of Dr. Charles Wheeler Forrest Young, at a salary of £500, rising to £600, a year, as an additional assistant medical officer of health.

THE application for a Royal Charter made on behalf of the Royal British Nurses' Association will be considered on Monday by a committee of the Privy Council. The counsel for the applicants are Sir Horace Davey, Q.C., and Mr. Muir Mackenzie, Q.C.

H.R.H. PRINCESS CHRISTIAN has accepted the presidency of the Norwood Centre of the St. John Ambulance Association.

## ON CHOLERA, WITH REFERENCE TO THE RECENT EPIDEMIC AT HAMBURG.

BY PRIVY COUNCILLOR VON PETTENKOFER.<sup>1</sup>

THE outbreak of cholera in Hamburg in August naturally excited all Germany. The alarm—which the explosive occurrence of the disease in the chief commercial city of Germany, hitherto regarded as the type of a rational drainage system—spread throughout Europe and beyond it, and was not less than that of sixty years ago, when cholera first advanced into Russia from Asia. It is excusable that in 1892, as in 1831, physicians and governing bodies thought first of all how to prevent the further progress of the destroying angel—how to localise it at Hamburg.

The rigid regulations in force throughout Germany to ensure this limitation may be compared with the military cordons and other measures of detention and isolation in vogue sixty years ago. They are based on the belief that cholera is simply an infectious or contagious disease, passing from the sick and their excreta to the healthy; and that the virus can only be taken with the food, and especially in water. This is now deemed to be absolutely proved since Professor R. Koch made his interesting and scientifically valuable discovery that the evacuations of cholera invariably contain the comma bacillus. The question is now limited to determining how this bacillus acts, how it may be destroyed and how its diffusion may be prevented. The strife against the bacillus is by most now deemed to be the only real prophylaxis, to the ignoring of the great mass of epidemiological facts which are entirely opposed to the mere contagionist view of cholera. Many confine themselves to the behaviour of comma bacilli in test-tube or plate and do not trouble themselves at all about the behaviour of cholera in its epidemic extension. Many years ago I said that the etiology of cholera appeared to me as an equation with three unknown quantities— $x$ ,  $y$ , and  $z$ . Let  $x$  be a specific germ disseminated by human intercourse;  $y$  something which depends on place or time, the "local disposition"; and  $z$  the individual disposition met with in all infectious diseases, both the directly infectious, as syphilis and small-pox, and others, as typhoid fever and malaria. The contagionists have eliminated the  $y$ , finding a sufficient explanation in Koch's discovery of the  $x$ , and seeing in individual tendency or absence of immunity the factor  $z$ ; so that if  $z$  be granted, cholera must occur should people introduce the bacilli into the mouth by unwashed hands, or take them into the stomach with water and food. The view is simple and easy, sufficient for him who only concerns himself with individual cases; but it does not satisfy the epidemiologist; for the latter knows that there are not only cholera-immune people, but also cholera-immune places, and that even in places where cholera has prevailed there are seasons when it will not spread, although introduced. This is what I mean by the  $y$ . It is not so easy to define as is the  $x$ , and so far one can only say that it is related to the quality and dampness of soil; but it is going too far to assert, as

some do, that Koch's comma bacillus is an unimportant, if constant, concomitant.

Man alone of all living creatures is susceptible to the cholera virus, and therefore experiments on animals with comma bacilli can determine nothing. The effects on the guinea-pig—previously prepared by the administration of soda solution—of an injection of a culture of bacilli, followed by one of laudanum, or the results of the intra-peritoneal injection of fresh cultures, are of no manifest importance as against the fact, confirmed a thousand times, that epidemics of cholera are never accompanied by epizootics. Now and then it has been noted that cholera has coincided with undue fatality amongst cats or poultry, but the association has been purely accidental. Guinea-pigs did not suffer during the late outbreak at Hamburg. Similar experiments on animals with non-pathogenic fungi—e.g., the bacterium coli commune—are fatal, and the bacteria multiply in the body just like the comma bacilli. So that the only indisputable experiments on infection with comma bacilli are those made on man. The invariable presence of comma bacilli in cholera stools proves that the fungus has something to do with cholera, but it is still a question whether it alone causes the disease and solely generates the virus. According to my localistic notions it cannot do this in places which are permanently immune from cholera, nor in places which, if occasionally susceptible, are yet at that time not disposed for cholera.

Now as Munich, in the year of grace 1892, in spite of much travel of persons from Hamburg and Paris, and in spite of its October Fair, remained free from cholera, I did not scruple to experiment on myself with the comma bacillus. Of it I had received from Hamburg, through my colleague, Dr. Gaffky, a pure agar culture, and from this my junior colleagues, Drs. Pfeiffer and Eisenlohr, prepared a sufficient quantity of broth culture to be taken by the mouth. As Gruber found that fresh cultures acted on guinea-pigs more powerfully than cultures several days old, I employed a broth culture which had been in the incubator barely twenty-four hours. One cubic centimetre of this was found to contain innumerable bacilli, after being diluted a thousandfold, so that I could take at one dose milliards of bacilli, very many more than one could possibly introduce by unwashed hands. Since Koch states that comma bacilli are destroyed by the acid of the gastric juice I was careful to take them on an empty stomach—viz., two hours and a quarter after my "frühstück"—when, according to my friend the physiologist, Carl von Voit, there would not be more than 100 cubic centimetres of gastric juice, with 0.2 per cent. of hydrochloric acid in the stomach. To neutralise this free acid the broth culture of bacilli (1 cubic centimetre) was taken in 100 cubic centimetres of water, containing 1 gramme of bicarbonate of soda. The vessel was afterwards rinsed with 50 cubic centimetres of water, so as to ensure my taking all the bacilli. I drank this cholera mixture in the presence of witnesses on Oct. 7th, it tasting like very pure water. Some were anxious about me, and begged that I would allow them to sacrifice themselves for their old teacher, but I wished to act on the old medical principle, *stat experimentum in corpore vili*. I was right in regarding myself as a *corpus vile*. I am seventy-four years old, have had glycosuria for years, have not a single tooth in my head, and only use my artificial teeth when I have to make a speech, not needing them for mastication; and I also feel other burdens of advancing age. Even if I had deceived myself and the experiment had endangered my life, I should face death calmly, for it would not be as a thoughtless or cowardly suicide. I should die in the cause of science, like a soldier on the field of honour. Health and life, as I have often said, are very great earthly gifts, but not the highest. He who wishes to rank higher than the brute must be ready to sacrifice even life and health for great ideals. However, to me the matter did not seem quite so tragic, for I was firmly convinced my  $x$  could not kill without my  $y$ .

[Professor von Pettenkofer then gives a detailed account of his condition, *de die in diem*, as to temperature, pulse, sleep, food, intestinal symptoms &c. On the 9th he began to have diarrhoea, and did not feel very well, having some abdominal discomfort; the diarrhoea increased on the 10th and continued up to the 14th. He took no medicine to control the diarrhoea, although advised to do so, lest it should become chronic.]

The motions were examined bacteriologically by Drs. Pfeiffer and Eisenlohr to trace the fate of the comma bacilli. The first loose motion contained a large quantity, and the subsequent watery stools contained pure cultures of the bacilli. On

<sup>1</sup> Abstract of a paper contributed by Prof. von Pettenkofer to the *Münchener Medicinische Wochenschrift*, Nov. 15th, 1892.

Oct. 14th there were only a few isolated bacilli, and by the 16th these had disappeared. Bacteriologists generally admit that comma bacilli do not excite cholera by invading the body from the bowel, but that, remaining in the intestine, they give rise to the virus, which is absorbed, and then causes choleraic symptoms. Virchow more than twenty years ago pointed out the resemblance of cholera to acute arsenical poisoning. How great must have been the amount of poison formed by the many milliardi of comma bacilli during their eight days' sojourn in my intestine. But I did not suffer at all from poisoning, was quite well, retained my appetite, had no trace of nausea, no fall of temperature, no albumen in the urine &c., and went about my daily avocations, so that I could not but conclude that, although comma bacilli may cause diarrhoea, they cannot cause cholera, either European or Asiatic. Possibly in Hamburg my experiment might have ended fatally, because there, on Oct. 7th, in addition to the Asiatic  $\alpha$  there was plenty of the Hamburg  $\gamma$  present, and it might have been that a much smaller dose would have excited severe cholera.

[When this experiment had terminated another was made in the person of Professor Emmerich, conducted on the same lines, except that he took a more restricted diet. A similar record is given of the daily condition in this case, the experiment commencing on Oct. 17th. Early next morning there was one fluid motion, and in the course of the day diarrhoea set in, so that on the 19th to 20th there were as many as fifteen to twenty colourless, watery evacuations, and an enema containing tincture of thebaica was administered and on the 20th one of tannic acid and opium. The motions became natural in the course of the 21st. Comma bacilli were found in the stools from Oct. 18th to the 28th, the motions on the 19th being almost pure cultures. On the 24th Professor Emmerich returned to his usual diet. Throughout his general condition was undisturbed, appetite retained, no pain in abdomen and only some weakness from the diarrhoea. Apart from the diarrhoea he had some hoarseness of voice and dryness of pharynx.]

These two experiments on man show that the comma bacillus does not generate the virus of Asiatic cholera, thus confirming Bouchard's results of the different effects of injections into animals of pure cultures and of the excreta (stools and urine) from cholera patients. Choleraic symptoms were not induced by the former, but only by the latter. Bouchard's experiments also show that the special cholera poison is only formed in the human organism. Perhaps one should concede that Emmerich and I did have a mild attack of cholera, as Koch and his numerous supporters would say, but I cannot admit the correctness of their view of the sufficiency of  $\alpha$  and  $\beta$  to cause an epidemic, to the exclusion of  $\gamma$ , no more than I can agree to the regulations enforced in Germany, Austro-Hungary and Italy, based on the discovery of the comma bacillus. Yet Dr. Baur and Dr. von Ziemssen, who have had large experience of cholera, affirm that the symptoms we exhibited were not those of which they had experience in cholera epidemics. According to the contagionist practice, on the discovery of comma bacilli in my evacuations, I ought to have been ruthlessly confined in the isolation barracks of Munich and my dwelling thoroughly disinfected. It seems a pity that this did not take place, for if it had, the contagionists would have been able to have loudly proclaimed that they had saved Munich from cholera, since Emmerich and I, by our stools, which were discharged without disinfection into the closets and drains, might otherwise have certainly infected the town. Joking apart, I too would become a contagionist, so comforting and so sparing of all further trouble is the view, if it could only be explained to me why so many places into which cholera has repeatedly entered have never had an epidemic. Lyons, which stands on the direct line of traffic between Paris and Marseilles, two infected foci, is a striking instance. Koch's explanation of this from the practice of washing linen on ships in the fast flowing Rhone and Saone can hardly apply, since a like practice obtains at Zurich and Stuttgart, which do not enjoy such an immunity. The contagionists neither attack nor dispute the epidemiological facts which I have published on this head; they only ignore them, for they harmonise so little with contagionist theory.

Since 1831 Hamburg has been visited by cholera fifteen times and Berlin twelve times (Table I.) The traffic by land and water between the two cities is extremely intimate, giving every chance for the transference of comma bacilli.

TABLE I.—CHOLERA IN BERLIN.

1873	June 14	Nov. 8	348,127	1001	2.9

The lack of correspondence as to time, severity of the outbreaks in the two places, is notable, especially in the years 1831, 1837, 1848, and 1849. Again, since 1831 neither of these towns has had a winter epidemic, whereas in Munich two out of the three outbreaks during the same period have been in the winter—viz., 1836-7, 1873-4. The seasonal variations in cholera are well shown in the statistics compiled by Brauser from all cases occurring in the kingdom of Prussia from 1848 to 1859, the numbers being grouped in semi-monthly periods. He found that the minimum of cases and deaths fell in the first half of April, the totals being for these twelve years seventy-one and fifty respectively; whilst in the first half of September they mounted to 57,395 cases and 31,048 deaths. Taking the half-monthly minimum of deaths as unity, the rise and fall in the incidence of the disease, as gathered from these statistics, may be thus given (Table II.):—

TABLE II.

Date.	Relative mortality.	Date.	Relative mortality.
April 1-15	1.0	October 1-15	380.2
" 16-30	1.2	" 16-31	316.1
May 1-15	2.2	November 1-15	227.2
" 16-31	6.7	" 16-30	125.3
June 1-15	30.2	December 1-15	84.9
" 16-30	43.9	" 16-31	60.1
July 1-15	61.0	January 1-15	23.5
" 16-31	108.6	" 16-31	17.8
August 1-15	233.4	February 1-15	10.2
" 16-31	430.2	" 16-28	6.6
September 1-15	620.9	March 1-15	3.3
" 16-30	510.2	" 16-31	1.1

How is it possible to account for this enormous rise from 1 to 620, according to season, by the properties of the comma bacillus? Why does the bacillus act so powerfully in Hamburg and Berlin at one epidemic and so feebly at another? There must be a seasonal influence: What is it?

Some think it is due to temperature, but although in Hamburg and Berlin epidemics generally begin in June and end in November, less often in October or December, yet there have been severe winter epidemics in Moscow, St. Petersburg, Munich and elsewhere. In Calcutta, where it is endemic, the minimum of cholera is in August or September, the maximum from January to April, mostly April, and the mean temperature in Calcutta in April is 30° C., of August 28° C.—i.e., is nearly equal. But if the comma

baocilli simply pass from man to man season should have no influence, for the temperature of the intestine is constant at 37.5° C.—a tropical climate. There is, however, at Calcutta another climatic factor—viz., the rainfall—which in April has a mean of 60 millimetres, and in August of 365 millimetres, the annual average being 1600 millimetres unequally distributed throughout the year. The rains begin in May and end at the end of September or October, the remaining months passing, perhaps, without a drop of rain. Now the monthly mortality of cholera forms a curve exactly inverse to that formed by the rainfall. Rain can hardly affect bacteria, especially comma bacilli, which flourish in moisture and are destroyed by dryness. In Prussia the same correspondence between rainfall and cholera holds, and perhaps the cause of the winter outbreaks at Munich may similarly be explained. The 1873 epidemic in Munich bears this out. It began suddenly in August and as rapidly declined, so that very few cases occurred during October, although at this time there was much movement of the population (changing houses, opening of schools &c.). At the commencement of November it broke out again, and by Dec. 4th it had reached a height of fifty-six cases daily, whereas in the whole of October there were only twenty-one cases reported. Inexplicable on the bacillary contagionist view, it can be readily explained from the localist standpoint. The germ  $\alpha$  was present in Munich long before the first case occurred. It is an epidemiological fact that cholera in certain places in India and beyond India may remain quiescent for months and then break out again, whilst even longer periods of quiescence must be admitted for the outbreaks in Hamburg, Berlin and Munich. In the summer of 1868, at Bellinghausen, in Essen, and elsewhere in the Prussian Rhine provinces, and in Westphalia, there were cholera epidemics, but nowhere else in Europe; and unless its autochthonous origin be accepted these outbreaks must be referred to the residues of the epidemic of 1866, which had been dormant in Essen. The great epidemic in Egypt in 1883 did not affect the Mediterranean ports that year. France saw in this the efficacy of quarantine, but in 1884 it broke out in that country. So in July and August, 1873, the local outbreak in Munich occurred after a very dry July, and was checked by an exceptionally wet August, but reappeared in the winter during another abnormally dry season. It is remarkable that Augsburg, which suffered so severely in 1854, and into which, in 1873, cases were introduced from Munich, no epidemic occurred in that year. This was not due to disinfection—it was before the discovery of the comma bacillus—but more likely to the excessive rains with which Augsburg was visited in 1873. There is no doubt that like atmospheric conditions played a part in the epidemic at Hamburg this year. The summer had been exceptionally dry and hot; the heat in August was almost unbearable, being about 5° above the average, whilst the rainfall in July, August and September was considerably below the mean:—

	1892.	Mean rainfall.
July ... ..	21 mm.	97 mm.
August... ..	53 ..	77 ..
September ... ..	46 ..	64 ..
	120 mm.	238 mm.

Naturally also the level of the subsoil water was lowered. The temperature, of the Elbe, which is taken in mid-stream every morning, rose in August to 22° C. Yet similar conditions of weather prevailed in other parts of North Germany, which were also susceptible to cholera, but where it has not yet become epidemic, and where probably epidemics will break out shortly. As regards the rainfall, only those places can be compared where observations have been continuous; for, as at Munich and Augsburg, neighbouring districts where the average rainfall is the same may differ very widely in particular years and seasons. The cholera germ from Russia has been more widely disseminated this year in France than in Germany, and that it only found a favourable soil in Hamburg must be due to a special reason. Hamburg for years has been making a special hygienic experiment on the largest scale, for it thinks that it can be cleansed by using an extremely impure water. The Hamburg waterworks distribute unfiltered Elbe water throughout the town and suburbs. In the mains are found dense layers of fungi of vegetable and animal origin; here and there a tap is plugged by the head of an eel. For drinking purposes the water may be filtered at home, or, if this does not suffice, thirst may be quenched by wine, beer, seltzer &c. For all domestic uses, for cleansing rooms and dwellings, courts and streets, the unfiltered Elbe

water is alone used, and then, owing to the excellent drainage into the Elbe, part of the refuse of the city must actually flow back into the water mains, thus rendering nugatory the sanitary aim of the drainage system. Above the reservoir the Elbe furnishes a purified water; but it becomes so contaminated on passing through Hamburg that within this area it cannot undergo self-purification. To be serviceable for consumption or domestic use its water should be further purified, as by filtration through sand, as is done at Altona, a few kilometres below Hamburg. At Cuxhaven the Elbe again becomes free from Hamburg impurities. It is plain also that the same degree of contamination may act differently on different soils, and all epidemics of cholera in Hamburg have shown essential differences between quarters situated upon marshy land and upon high ground. Reincke has shown that since the introduction of a drainage system into Hamburg the frequency of typhoid fever has diminished, except for some variations in abnormally dry seasons. Epidemics of typhoid fever have this in common with cholera; but that Hamburg, in spite of its excellent drainage, may still be a fruitful soil for typhoid fever is shown by the epidemics of that disease of 1885 to 1887, whilst this year, associated with cholera, there has been a notable increase in typhoid fever. We are more fortunate in Munich, for formerly, with very good drinking water, but high level of subsoil water, we often had more than twenty deaths annually from typhoid fever among 10,000 inhabitants. However, since 1881, with subsoil water at a very low level, the deaths have not exceeded one. The once notorious typhoid soil of Munich has been gradually purified by sanitation, and we regard with some confidence any fresh visitation of cholera. In Hamburg itself a system of sand filtration was commenced until the cholera intervened, but the new waterworks are expected to be completed in the autumn of 1893. These works on a gigantic scale are under the direction of Engineer-in-Chief A. Meyer and will cost many millions of marks, but not so much as Hamburg has lost by the cholera of 1892.

The part played by water in this epidemic has been variously explained. The "drinking-water theorists" think that comma bacilli from Russian Jews found their way from the Elbe to the reservoirs and were thus distributed throughout the town—a most plausible and comfortable explanation for the laity and the profession. Still experience does not always fit in with this theory, for outbreaks quite as "explosive" have occurred without the drinking water being at fault. I leave it undetermined whether in 1892 the Hamburg water operated directly as drinking water or indirectly as foul usable water. It is strange that in spite of the most careful search they should have had the misfortune not to find any comma bacilli in the Elbe water or in the water from the Hamburg mains. This is said to prove nothing, since other bacteria may be present which fluidify nutrient gelatine. Yet Koch found his bacilli in a Calcutta tank, and Fraenkel in the water of the Rhine, where lay a boat containing a case of cholera. The water of the Indian ponds is not only drunk, but used for bathing and washing. The comma bacilli escaping from the human intestine into river or pool must be overcome by other bacteria and disappear very rapidly. I am not asserting that the comma bacillus has no etiological importance, but I believe it impossible for it to be the  $\alpha$  which can excite and develop cholera epidemics apart from the  $\gamma$ . And if we have found a specific micro-organism in an infectious disease, we ought to hope that some means may be found thereby to combat the disease. Tuberculosis is a striking example. The discovery of the tubercle bacillus in the sputa of phthisical patients was scientifically as interesting and important as that of the comma bacillus in choleraic evacuations. But since the discovery of the tubercle bacillus, which is older than that of the comma bacillus, neither more nor fewer people have died from phthisis than formerly.

The present protective measures against cholera rest entirely on purely theoretical contagionist bases. We have become very one-sided, thinking that cholera must be met by prevailing theories and not that theory should follow after cholera. It is deemed most important to seize the comma bacillus from the first case occurring in a place, and when its presence is proved, to isolate the patient, disinfect his excreta and his dwelling, and then one thinks that the place, be it village or town, is protected from cholera. If in Hamburg the first case had been isolated and disinfected, the epidemic, so they think, could not have broken out. Until a case comes to official knowledge it is in contact with others and the evacuations are not disinfected; and, when

reported it must be determined bacteriologically whether it is a case of Asiatic cholera or one of cholera nostras. Then the source of infection must be traced, and often the disease breaks out in many parts simultaneously, as it did in Hamburg, adding to the difficulty of the task. Nothing but absolute stoppage of all traffic could avail, and that would be a greater misfortune than the cholera. The spread of the cholera germ is not to be prevented, either in India or outside it, by isolation, disinfection, cordons, quarantines &c. Just as, in spite of custom houses, goods are still smuggled over the frontier, so the bacteria and viruses will be smuggled through all our barriers. Still, improved sanitation may do much to prevent the smuggled germs gaining a foothold. In the sixties, when Prussia, Belgium, Holland and France had most severe epidemics, Great Britain was only moderately invaded, and since 1866, in spite of its colossal traffic with the motherland of cholera, and the introduction of numerous cases from other lands, England has not had a single local epidemic, neither during the cholera time on the Continent from 1871 to 1874, nor during 1884 to 1887. Even this year cholera has not invaded England from Hamburg, Russia and France, although England (London) was the only land which fearlessly trafficked with ships coming from infected ports.

If one cannot act against the introduction of the germ  $x$ , one must seek to act in the directions of  $y$  and  $z$ , and strive to make places or people immune. Every epidemic shows that many do not possess the  $z$ , the individual disposition, and that they are immune. Some are protected by their own serum perhaps, and it may be possible to ward off cholera, like variola, by protective inoculation. The contagium of variola was not mastered by isolation and disinfection until vaccination proved successful. Cholera is not contagious like variola, but depends on local conditions, and susceptible places may be rendered immune, like Fort William in Calcutta. There have been in other places as severe epidemics as this in Hamburg, but where all these measures of isolation &c. were not in vogue, and where the disease arose and subsided as quickly as it did at Hamburg.

[Professor von Pettenkofer here contrasts the epidemic at Munich of 1854 with the Hamburg outbreak. He goes on to contend that neither military cordons, as in Russia, nor quarantines, nor the forbidding of fairs &c., have any influence, and fears that next year, if there is not much rain, it may spread over Germany.]

The contagionists say that when cholera breaks out in a place the rules demanded by their theory should be enforced. I am convinced that this is a mistake. I know of cases where nothing of this sort has been done and the epidemic has been remarkably mild, much milder than where the contagionist practice has been carried into effect.

[In proof of this Professor von Pettenkofer cites at some detail the outbreak of cholera in Bavaria in 1836, and shows that the authorities acted on the anti-contagionist plan, only transferring those cases to hospital which could not be cared for at home, and not interfering with public meetings and feasts. At that time Munich was in an insanitary state, yet the epidemic was the mildest of the three it has experienced. There was no dread of cholera in those days which he remembers in his youth. Nothing was known of bacteria, and cholera was attributed not to comma bacilli but to the genus epidemicus. Traffic in and out of Munich was not deranged.]

He concludes by expressing the hope that the recent appearance of cholera in Europe will lead to a restriction of regulations based on merely theoretical grounds, so greatly hampering free intercourse and even contrary to humanity, without any practical effect, and that the money expended on them will be devoted to attainable sanitary aims. Reflecting how many millions must have been thus sacrificed to theory in a single town like Hamburg, it is inconceivable, he says, "how opposition can be made to the new military Bill before the Reichstag, which is based on much sounder grounds than the contagionist rules against cholera. I live and die in the conviction that our army will subdue enemies who would invade us from the east or the west, but not that our capture of bacilli, our cholera barracks, isolations, disinfections, prohibitions of entry and transit, or our quarantines can prevent the invasion and the dissemination of cholera."

VACCINATION GRANT.—Mr. James A. Bright, M.R.C.S., has been awarded, for the eighth time, the extra vaccination grant as public vaccinator for the Glastonbury district of the Wells Union.

## CHOLERA.

### CURRENT NOTES, COMMENTS AND CRITICISM.

THE exceptionally warm and moist or, as it is commonly termed, "muggy" weather which has recently prevailed has probably not been without its effect on this disease, and the number of cases has, perhaps, been somewhat increased by it. Although there are instances on record of the continued prevalence of cholera in winter, the disease usually "dies down," as it is sometimes expressed, during the cold weather, and it is very rare for an epidemic of cholera to manifest itself or extend with any epidemic strength in the winter season. According to the official accounts the disease has died out in Paris, but several fresh attacks have occurred in the north of France. The *Temps* reports nine new cases and two deaths at Etaples, one at Courteville and two fatal cases at Calais. Five fresh cases have been reported from Arras, one from Boulogne and one from Bargnes. Five cases are reported from Avion. One case of choleraic disease was admitted to the hospital at Lyons which town, with the exception of a slight epidemic in 1854, has hitherto escaped cholera. From the Hague we learn that since the outbreak of the epidemic in Holland 225 persons have died of it. The number of deaths from the disease last week was 22, most of which occurred in the province of South Holland. Sporadic cases of cholera continue to occur, however, at Breda, Utrecht, Terheyden, Leeuwarden, Woerden, and Steenberg, as well as at several places in the vicinity of Woerden. It has altogether disappeared as an epidemic in Hamburg, notwithstanding that an occasional case of choleraic diarrhoea is reported from time to time. The Imperial Office of Health at Berlin has declared Hamburg, Altona and Stettin free of cholera, and the ships from those ports are no longer subject to sanitary inspection. At Budapest there have been altogether 1018 attacks and 440 deaths from the commencement of the outbreak; and the disease still lingers in the city giving rise to some fresh cases—from eight to twelve—daily. The last reports, however, indicated great improvement, as there were only two fresh cases and two deaths in twenty-four hours. Almost all the schools at Budapest have been re-opened. It is stated that cholera is spreading in the western, and especially in the southern counties of Hungary. A severe outbreak took place recently in the village of Aradacz, where fifty-seven deaths are reported to have occurred in a population of 1500. The latest news from St. Petersburg is not altogether satisfactory. The exceptionally mild weather has apparently given rise to a recrudescence of the disease. There were 12 cases and 5 deaths on Nov. 14th. The majority of the cases are from the north side of the Neva, where the water-supply is stated to be bad. Local conditions usually exercise a powerful influence, and this seems to have been the case in the following instance: One of the latest attacks is that of the English manager of a large cotton mill, where, it is stated by *The Times*, the first authenticated case of cholera at St. Petersburg took place. It is alleged that many cases of influenza have also occurred lately at St. Petersburg. Russia's contribution to the cholera death-roll seems to have been a terrible one, amounting altogether to over 220,000 victims. The famine-stricken districts of the Caucasus have suffered most. In Astrachan there were 7873 deaths; in Veronseh, 9468; in Vintka, 4440; in Samara, 14,962; in Saratoff, 18,992; in Tamboff, 8039; in the district of the Don, 17,751; and in the Caucasus, 63,268. This epidemic of cholera followed in the wake of famine and an epidemic of typhus fever, which is said to have proved even more fatal than the cholera. Confronted with these terrible scourges, and in dire need of sanitary improvements in every town and district of the country, it certainly strikes one with amazement that Russia still seems bent on spending large sums of money in the pursuit of military ambition and a war policy. It does not appear that our latest and more extended study and observation of cholera during the present epidemic is likely to end in any precise scientific unanimity regarding its causes and methods of extension. There seems to be great divergence of opinion in these respects at the

present moment, Professor M. Peter, of the Necker Hospital, Paris, for example, having set forth his views in a clinical lecture on "Indian Cholera, or Cholera Nostras," with reference to the late outbreak at Nanterre and other occurrences at Paris, in a vigorous spirit of unbelief in the current orthodox doctrines. We would call attention to the extremely interesting article "On Cholera, with reference to the Recent Epidemic at Hamburg," by Privy Councillor von Pettenkofer. Apart altogether from the scientific value of the paper, it is impossible to withhold our admiration for the calm courage exhibited by Professor von Pettenkofer and Professor Emmerich in undertaking experiments of the nature described. Professor von Pettenkofer considers that the contagion theory has not been confirmed by the Hamburg epidemic. When cholera breaks out epidemically there is always local predisposition. Individual predisposition without favourable local circumstances will not, in his opinion, produce a cholera epidemic. He places no reliance on the results of the inoculation experiments on animals, and thinks that man is the only animal on whom any experimental results can be relied upon. With the view of testing the inadequacy of individual predisposition to account for an attack of cholera he, together with Professor Emmerich, swallowed considerable quantities of cholera bacilli without any more serious consequences than diarrhoea, which might, of course, be induced by any septic agent. Bacteriological examination of the excreta proved, at any rate, that the experiment was thorough, so far as the individual experimenters were concerned. It has been done before and with similar negative results. We may incidentally refer here to the "Report on the Sanitary Measures in India in 1890-91," just published, for some information regarding the Hurdwar fair and the comma bacillus, which may prove interesting in this connexion. It will be remembered that we had previously called attention to the fact that samples of water taken at the Hurdwar bathing place in 1891 were found to contain quantities of the comma bacillus. It was calculated that the fair was attended by about 700,000 persons, who crowded to the sacred ghat to bathe and take the holy water into their mouths. The appearance of the comma bacilli in the water was accounted for by the presence of cases of choleraic disease at the fair, who either by themselves or by infected articles of clothing introduced the bacilli into the sacred pool. Had an outbreak of cholera occurred subsequently among the pilgrims the positive evidence would naturally have been regarded as something more than a coincidence, and the presence of the bacilli would have been considered its cause; but no such outbreak took place among the crowds of pilgrims returning from the fair. Of course there is no evidence to prove that the bacilli discovered in the samples of water were absolutely identical with Koch's comma bacilli. We have already alluded to Professor Peter's clinical lecture at the Necker Hospital, Paris. It gives a very interesting description of the events that happened at Nanterre, and compares them with some cases at Breteuil in 1884. The lecture is published in the *International Medical Magazine* for October. He boldly strikes at the very root of the specific nature of the cholera-cause, as it were, for he holds that cholera nostras and Indian cholera present the same symptoms, the same termination, the same contagion and the same epidemic manifestations, so that they are, for all practical purposes, one and the same malady. The object of the lecture is to show how a series of morbid troubles can increase and become an epidemic. Diarrhoea first develops, which becomes more and more severe, and finally cholera is produced. This attempt, however, to cut the knot of a pathological difficulty is not likely to be regarded as a successful or satisfactory procedure from a scientific point of view.

*Appropos* of the disappearance of cholera from Hamburg, a statement to the effect that German toys were manufactured at Hamburg and sent to the London market brought a shoal of letters to a contemporary from persons interested in that trade contradicting the statement that such toys were manufactured in Hamburg; the fear of cholera infection being conveyed to our children in Noah's arks is consequently illusory. With the aid of a lively imagination applying a spur to the fear of possible infection through any and all sorts of channels, it is impossible to impose limits to people's alarmed credulity. But the Japanese authorities were credited a few years ago with going further in the direction of precautionary measures than anybody else, for it was alleged that on hearing that two Japanese sailors had died of cholera and had been thrown overboard, they immediately prohibited fishing along the coast!

## THE CHOLERA IN FRANCE.

(FROM OUR SPECIAL CORRESPONDENT.)

### A VISIT TO CAEN.

*Sanitary Measures against the Havre Steamers.—Dogs and Cholera.—The Legality of Porous Cesspits.—Gutters as Sewers.—A Town for Tourists.*

FROM Havre small steamers generally sail twice a day for Caen. Other steamers go to Honfleur and to Trouville. The mouth of the Seine is so wide that these places cannot be reached by train, without travelling inland as far as Rouen. During the height of the epidemic, the ports on the opposite banks of the Seine took alarm and sought to impose all manner of measures against the steamers that brought passengers from Havre. This was the more absurd as these measures could not be enforced against the passengers who came by train. At best they could only lessen the danger by reducing the number of passengers; but as the cholera had already been brought over before any precaution whatsoever was adopted, the suppression of the steamship-service could not in any way be justified. The Minister of the Interior, however, had to intervene so as to make the local authorities understand that, whatever might be done with regard to persons coming from foreign countries, the freedom to travel within the country itself could not be interfered with. Thus the steamers resumed their service, but measures were nevertheless taken against the passengers.

I crossed over from Havre on Oct. 25th. Three days previously there had been another death at Havre which was attributed to cholera. It occurred under very curious circumstances. The victim was a lady related to one of the professors in the town. She was devotedly attached to a dog, which had been suddenly seized with violent vomiting, diarrhoea and cramps. The animal died very rapidly, and the carcase was in such a condition that it was not judged prudent to bury it in the garden. It was given to the scavengers and placed on board the boat which takes sludge out to sea every day. Shortly after the lady, who had nursed the dog throughout, was seized with the same symptoms and died at the end of three days' illness. This case has excited great interest in medical circles at Havre, and regret is expressed that the dog's symptoms were not more carefully observed. Of course the owners of the dog were taken altogether by surprise, and suspecting no danger had taken no precautions.

After some two hours' sea journey the Havre boat reached the mouth of the river Orne, which passes through the town of Caen, but instead of steaming up the river, we hoisted the yellow quarantine flag and made for the jetties situated a little distance further along the coasts, and built at the entrance of the maritime canal, by which ships of larger tonnage reach the town of Caen. Here we were boarded by a medical officer under the armed protection of custom-house soldiers. This gentleman went all over the ship, looked at all the passengers, and then gave us permission to pull down the yellow flag and proceed to Caen. We now returned to the river Orne, and an hour's pleasant journey up the narrow stream, winding through a picturesque country, brought us to the landing-stage at the historical and antique capital of the Department of the Calvados. Here again an official came on board flanked by guards, who would not allow anyone to land until they had given in full their names and addresses. On landing the passengers were conveyed under military escort to an office, where those who did not intend staying at Caen, but were proceeding to some other town, had sanitary passports given to them. The passport was identical with the one given at the frontiers. The bearer has to report himself within twenty-four hours to the authorities of the town where he may be going. Any neglect entails imprisonment of from three to fifteen days. Excepting that our luggage was not examined and the soiled linen seized, the same precautions were taken at Caen against passengers coming from Havre as are taken at the frontiers against passengers coming from Russia, Hamburg and other infected places.

That considerable alarm should be felt at Caen when it was known that travellers were coming from towns where cholera prevailed is only natural if we take into account the utter want of sanitation which characterises this place. Some idea of the neglect which prevails in matters relating to public health may be gathered from the fact that the muni-

opality has not even taken the trouble to draw up vital statistics. At the *Etat Civil*—which corresponds to our registry office, with this important addition, that the registration comprises not only births, deaths and marriages, but the far more complicated records relating to the compulsory military service—there were but four clerks. As a result, no one knew what was the death-rate of Caen; no one knew even what was the average number of deaths at Caen. I was therefore obliged to trespass on the time of these four clerks, and one by one the death registers of the last ten years were pulled down from their dusty shelves, straps and tape undone, and the total number of deaths for each year ascertained. The number of deaths occurring per annum from 1882 to 1891 were as follows: 1253, 1278, 1205, 1344, 1382, 1272, 1357, 1200, 1433, 1470. This is equal to an annual average for the ten years of 1319.5. The population in the first census taken during that period was 43,800, and in the census taken quite recently 46,417. The high death-rate for the last two years is attributed to the influenza epidemic. The number of deaths in the town, I was especially asked to note, was greatly increased by the numerous charitable endowments for which Caen is celebrated. There are the lunatic asylum and the hospital and other institutions, where some 300 persons died in the course of the year, the majority of whom were not inhabitants of Caen. Also there were some seventy stillborn infants counted among the deaths of each year. But these arguments apply to almost all large towns, and are not taken into consideration; therefore, and calculating according to the last census, there is an average death-rate for the ten years of a fraction over 28 per 1000. But, if we estimate the population for the ten years at the average of the last and the previous census, then the death-rate exceeds 29 per 1000; and, finally, if some 200 deaths be deducted on the ground that, though occurring within the town, they properly belong to districts outside the town, we should still find a death-rate of 24 to 25 per 1000, which, for a town of less than 50,000 inhabitants, may be considered very high. The average death-rate for the fifty-one towns in France of more than 50,000 inhabitants is 25.61 per 1000, and no one pretends that this is satisfactory.

Probably the death-rate of Caen would be higher still but for the one great redeeming fact that the town possesses a good water-supply. From the Moulines, a hill some seventeen miles distant, 8000 cubic metres of pure spring water are brought to the town in a closed aqueduct; this water comes from an altitude of 120 metres. The town of Caen is only six metres above the level of the sea; the water is therefore delivered under pressure. The water has been recently analysed in Paris and found to be pure, but it is exceptionally hard. This is so serious a grievance with wine and spirit dealers, that one enterprising tradesman has started a water-distillery. The town water soon thickens, and spoils the appearance of the wines and spirits with which it is mixed. Now, however, the trade is provided with pure distilled water, which can be consumed without danger to the public.

Though there is a good water-supply, Caen is in the same position as many other towns: the municipality cannot compel the inhabitants to drink only the town water; but everything is done to encourage the consumption of this pure supply. There are no less than 260 public fountains in this small town. Thus the inhabitants, without having to go any distance, are able to obtain pure water gratuitously. There are, besides, 780 subscribers who have private supplies of the town water within their own dwellings. I was assured that most persons preferred drinking the town water; but it was admitted that there were wells and cisterns, and that some persons drunk either the rain-water collected in their cisterns or the water from their private wells. This is the more deplorable as the drainage of the town is most defective. The municipal authorities profess to believe that the cesspools are water-tight, but such profession is only a matter of form; they know well enough that many cesspools leak. Even if the cesspools were water-tight, the authorities admit that there are *bétoires* in the town. As I have already explained, a *bétoire* is a well or deep hole dug in porous soil, into which houses drain their slops, and all the liquids filter away in the subsoil. It appears that the authorities cannot legally suppress a *bétoire*. The question has been tested by the municipality. An influential resident at Caen was prosecuted because he would not close his *bétoire*. The magistrate held that the law could not interfere with the landowner, who was at liberty to dig as many *bétoires* as he chose. It was only when such *bétoires* caused a nuisance dangerous to public health that the

law could enforce the suppression of the nuisance, but not of the *bétoire*. Thus the town lost the case, but nevertheless it has succeeded of late in abolishing a considerable number of *bétoires*, only this was achieved in a roundabout manner. A nuisance had to be proved, and in order that the nuisance should not be renewed the landlords of their own accord suppressed the *bétoires* giving rise to the nuisance. But *bétoires* are still tolerated in those houses that are below the level of the street. The system of slop drainage is to drain all slop water into the street gutter; but when the backyard and entrance passage of a house are below the level of the street, *bétoires* are still tolerated, and all the slops allowed to percolate into the subsoil. The closets in some houses drain into cesspools, more or less watertight; other houses have a rude sort of pail system. Scavengers, with more or less irregularity, come and remove these pails, and the contents are converted into manure. But there are some houses which simply have no closets at all. Needless to say that these contribute largely to the foulness of the streets, the gutters, and the sewers into which these gutters flow.

Caen, it will be perceived, is drained on the old French principle that the sewers should only receive rain and slop water. Perhaps this accounts for the very unsatisfactory position of the main sewer outfalls. One portion of the sewage is discharged into the dock which communicates with the maritime canal, the remainder into the River Orne, before it reaches the town. This portion of the sewage flows back through the town on its way to the sea. By the opening of the dock gates a flush is occasionally created; but though this may be of some service, it is quite evident that the sewers ought not to have their outfall in so small a sewer as the Orne.

In spite of all these organic defects, which show that mischief is more likely to arise from within than to come from without, an official poster has been affixed to the walls of the town, headed "Sanitary Measures." It consists of a lengthy decree issued by the Mayor and approved by the Prefect of Police. The decree forbids the admission into the town of all rags, secondhand clothes, bedding, leather, woollens and animal fragments, unless accompanied by a special permission, which must be given only by the Mayor, and after such articles have been disinfected. Even if the articles come from a non-contaminated district or country they are to be examined and disinfected if judged necessary. Another clause forbids the throwing into the streets of all dejecta; these must be thrown only into the cesspools or the closet pails. Considering that there are some houses that have neither cesspools nor pails, it is difficult to see how this clause of the decree can be strictly observed. I am a witness, on the contrary, that even in some of the best and most frequented streets of Caen dejecta are thrown into the gutter, and this in broad daylight. Another clause forbids the throwing of slop water in the passages, courts, on the pavement—in fact, anywhere except in the gutter. But gutters are small, slop pails are large, and we all know how the scullery maid delights to send the contents splashing forth. This, then, was another sanitary measure more easy to decree than to enforce. The decree goes on to say that the inhabitants should maintain the greatest cleanliness, should sweep and wash out their courts and alleys at least twice a day, as also the gutter passing in front of their houses. Finally, the authorities place gratuitously at the disposal of the public the disinfecting stove, undertake to disinfect any room or apartment, and to give disinfectants to anyone who may require the same. In the hotels there is another decree posted ordering hotel-keepers to report all travellers coming from infected towns, to watch them, and to report at once if they manifest any suspicious symptoms of illness.

In view of these regulations and decrees it was strange to observe slop water on all sides, even in the best streets of Caen. At times, in the lower levels, this slop water forms small stagnant pools. Thus there is constant saturation of the subsoil and evaporation. It did not appear that the decree mentioned above had been strictly enforced. At the end of the Boulevard St. Pierre especially foul odours are noticeable. At this point there are some atrocious latrines, and by their side washerwomen, who wash linen in what appears to be a main sewer. The water issues from under the street and sees the light only for a few yards previously to falling into the dock beyond. If this is allowed in the very centre of the town and on a broad boulevard, what must happen in the back courts and alleys? Yet as Caen is an attractive town for tourists it would be well worth

while to improve its sanitary condition; if not for the sake of the inhabitants, then for the sake of the increased income the tourist would bring. Caen is rich in historical and archaeological treasures. Here lie buried William the Conqueror and his wife Mathilda, each in a church they themselves had built, and which are amongst the most perfect specimens of Norman architecture still extant. There are many other buildings, churches, private houses &c. dating from the eleventh to the fifteenth century. Most persons who make tours in Normandy and Brittany would find it convenient to visit the town of Caen. This centre of ancient Norman civilisation is well worth being considered as the crowning object of such a tour. But if the local authorities desire to attract a larger number of American and English visitors they must look to the drainage of the town, and effect very material improvements. This also will be found to be the best protective measure against the possible advent of cholera.

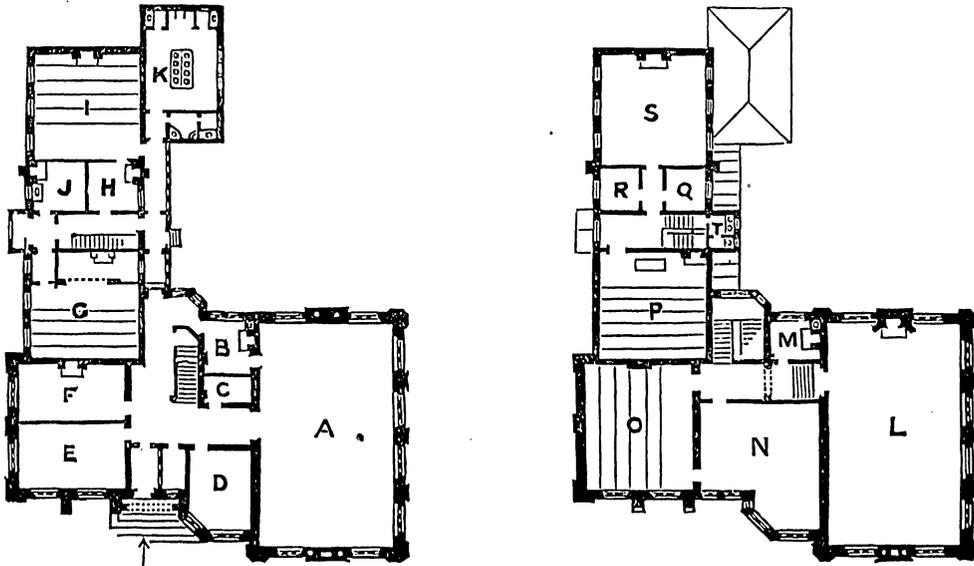

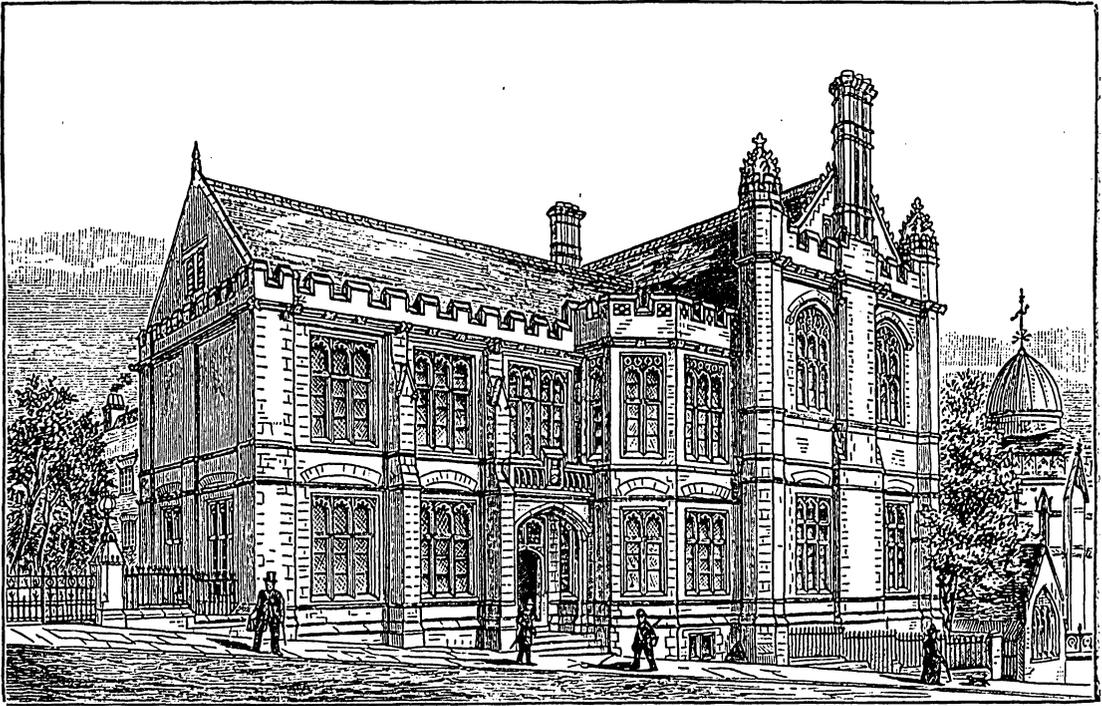

## THE BRISTOL MEDICAL SCHOOL.

WEDNESDAY was an important occasion with the Faculty of the Medical School at Bristol. In the early afternoon there was the formal opening of the medical wing of the Bristol University College, built to replace the old medical school at Bristol, which, by the brilliancy of its former students, has made for itself such a distinguished name in the country. The old buildings have long been felt inadequate and are insufficiently dignified for the home of an important and increasing body like the Bristol Medical School. A large sum of money having been raised by subscriptions the council found it possible last year to commence the building of an adequate structure such as would not only cover the needs of the School, but offer a permanent home for the large reference library now being formed by the Medico-Chirurgical Society. The new building, as part of the future grand front of the Bristol University College, has been the subject of careful architectural treatment, the designs being on lines thoroughly English and in keeping with the style prevailing in early Tudor days. The medical and the engineering wings will cost something like £10,000. The feature of the day's proceedings was the presence of the President of the Royal College of Physicians, Sir Andrew Clark, who cordially accepted the invitation of the Dean of the Faculty, Dr. E. Markham Skerritt, to formally open the spacious and excellently fitted wing.

The Chairman having adverted to the importance of the occasion, Mr. Albert Fay, chairman of the Council of the College, explained the present position of the College and the medical school, and why a new building was needed.

Sir Andrew Clark, on rising to declare the building open, said the occasion which had brought them together was regarded, and justly, as one of supreme importance to the ancient city of Bristol, and all joined in the expression of the hope that the movement about to be crowned that day might contribute to the life and work of the next generation. To those accustomed to look only upon the surface of things, this language would appear exaggerated; but to those who penetrated deeper it would not seem strong enough. They had met to inaugurate the reopening of the Medical School of Bristol, begun by the doctors, carried on by the people, incorporated by the College, and now crowned, or about to be crowned, as its medical faculty; they celebrated its second birth and prayed that its second life might be a life of strength, of usefulness and of honour. The existence of a medical school in Bristol was of more importance to the people than to the medical profession; and the participants in the reorganisation of the medical school of the people, the College, and the municipality revived the high and true ideal of the civic life which regarded it as a family life. Of the agents actively at work in evolving the prosperity of a great city such as Bristol the two chief were the moral agent and the health agent; the moral agent, the true and only source of all abiding good, the neglected remedy of social evils and labour disaffection and unreason; and the health agent, the physical framework which penetrated and influenced all that was in man and all that issued from his thoughts. The conditions necessary to the health of the community were not only numerous but complex and constantly varying. Advancing civilisation brought increasing complexities into the conditions of human life, and if human

life was to be continued in all its fulness and fruition they must acquire not merely a knowledge of those conditions, but also the power of fulfilling, controlling and readjusting them to the varying life and service of mankind. From time to time the problems of existence in fresh conditions must be reconsidered, and renewed endeavours must be made to discover and set forth the most favouring conditions for birth and growth, for education and development, for work and play, for the maintenance of health and resistance to disease, for adjustment to environment and the evolution of fresh capacities and functions for the prolongation of life and the further physical, mental and moral development of the race. The investigation of all such subjects, and the proper methods of dealing with them, came within the domain of medicine. In a medical school they had a centre of medical and general knowledge, and collected together within it a body of highly-educated men who were striving to find out the widest and most fruitful applications to the practical business of life. The City of Bristol could not have a great medical school in the midst of it without deriving many advantages from its operations and collateral influences; it would bring to the city the latest and best knowledge in practical medicine and surgery and in the department of public health. Bristol was happy in having a medical school which had a justly high reputation, which had produced many distinguished men, which had at various times made substantial additions to their knowledge, and which had done admirable work in the cure of disease, and in the improvement of surgical processes. And now the old school being no longer equal to the educational requirements of the time, they were about to enter into possession. In design and construction, arrangement and fittings, the new school was worthy the highest praise, and might be said to be second to no other provincial school. But it had one defect, which was so serious that, unless it was repaired, the school could neither adequately discharge its functions nor take rank with any leading medical college. The school had no State licence for experimental research, and, as far as he could learn, it had no intention to apply for one. He knew—no one knew better—that many estimable and exemplary people, moved by the tenderest feelings and actuated by the highest motives, refused, on the ground that experimental research was both unnecessary and cruel, not only to sanction such a method of inquiry, but to hold any relations with institutions in which it was sanctioned. He had the profoundest sympathy with such persons. He honoured their feelings and respected their motives, but, firmly convinced that they had been prejudiced and misinformed, he strongly dissented from a judgment founded on inaccurate statements and erroneous considerations. The law of vicarious sacrifice was a law of the physical, mental, moral and spiritual life, and no living sentient being could escape from its operation. It was folly now to argue the question whether experimental research had contributed to the advancement of theoretical and practical knowledge, for it was certain that no substantial advance had been made in physiological knowledge without the assistance of this method of research. By experimental research surgeons had been enabled to arrest or cure disease, and Koch discovered in the presence and action of the tubercular bacillus the true cause of tuberculous or consumptive disease. This discovery had not only thrown a flood of light upon the natural history of consumption, but had enabled them to discover its presence when otherwise unsuspected, and to bring about a successful revolution in the treatment of surgical tuberculosis. By experimental research they had discovered the condition for using with efficiency and safety almost all the stronger and most useful drugs, and by experiments upon animals they had discovered the nature and relations of infectious diseases, and had learned how in some measure to prevent the development and to control the spread of fevers, cholera and anthrax. If experiment were to be suppressed, and if consistently the use of knowledge acquired in this manner were to be rejected, then it was certain that the art of preventing and of curing the diseases of beast and man would decay, and that physical and mental degeneration would follow. The medical school, having been built, fitted and finished, the question arose, How was that costly building to be maintained in efficient working order? Some people would reply that the building was a doctor's business; why do not the doctors maintain it? But in answer to this he would say that the school was more for the advantage of the public than of the profession, and he held that the public was bound in honour to pay for what was consecrated to its service;

and in the second place, the doctors, speaking quite frankly, were much too poor to be called upon in a business of that kind to add to the list of their gratuitous services, and even to pay for services which they rendered to others. Men would ask why the medical school should not be self-supporting. Well, he doubted if any provincial medical school was ever, from a strictly business point of view, self-supporting. The Bristol Medical School could not be made self-supporting, and he should suspect its efficiency and dignity if it were so. They had not only a good medical school, but, with the exception of one defect, which he hoped would be soon made good, there were moral interests which would not be ignored. If they believed, as he did, that the moral idea preceded and determined all true and abiding prosperity, they would regard the maintenance of that school as one of the paramount duties of their citizenship.

Mr. Lewis Fry proposed a vote of thanks to Sir Andrew Clark for coming amongst them to open the school and for his able address. He was very grateful to him for the enlarged view which he had put before them of the functions of municipal government. With regard to Sir Andrew Clark's opinion on a certain subject, whether they agreed with him or not they must be thankful to him for the courage he displayed in candidly expressing his views on that difficult question.

Dr. E. Markham Skerritt, Dean of the Faculty of the Medical School, seconded the vote of thanks.

The banquet was held at the Royal Hotel, Bristol. Sir Andrew Clark presided, and he was supported, not only by a representative gathering of the Faculty, but by many leading citizens.

The whole of the arrangements connected with the dinner were entrusted to and well carried out by the following committee:—Dr. E. Markham Skerritt, Dr. Shingleton Smith, Prof. Lloyd Morgan, Mr. Munro Smith and Mr. Paul Bush.

## MUNICIPAL HONOURS AND MEDICAL MEN.

LAST year we expressed our gratification at the number of medical men upon whom had been conferred by their fellow citizens the high and distinguished position of mayor, and it is once again our pleasing duty to welcome those who have been called to this honoured office. Within the Dome at Brighton, on the evening of Nov. 9th, nearly three hundred guests assembled to honour Dr. Joseph Ewart, J.P., F.R.C.P., by a banquet. Dr. Ewart—who, as Sir Joseph Fayrer said in proposing the toast of "The Mayor," is eminently fitted for the office by his "high personal character, great scientific attainments and firm methods of conducting business"—has been elected for the second time to fulfil the duties of mayor to the borough of Brighton. Dr. Ewart, who is a native of Cumberland, took his M.D. degree at St. Andrews University in 1853. In the service of the East India Company he spent a considerable portion of his life, and was in medical charge of the Meywar Bheel Corps at Kherwarra during the time of the Indian Mutiny. After receiving high distinctions from the Government, owing to falling health he returned to England. Dr. Ewart has ever taken an active part in local affairs. His first election to the town council of Brighton was in November, 1884. He was elected a member of the watch and sanitary committee and the lighting committee. Brighton is to be congratulated in possessing for its Mayor a man of such tact and energy as Dr. Ewart—Dr. A. R. CROUCHER, who has been chosen by the borough of Hastings to act in the capacity of Mayor, took the degree of M.D. at St. Andrews University in 1858, and is also M.R.C.S. Eng. and L.S.A. After practising for two or three years in London he went to St. Leonards, on account of ill-health, where he has since resided. In 1874 he was elected alderman for Hastings, and in that capacity was the means of the sanitary committee of the town being formed. He acted as chairman of this committee till the year 1880, and by his advice the Hastings sanatorium was built. Great interest has been taken by him in the water-supply to the borough, and it was mainly owing to his influence that the new waterworks at Filsham were brought forward. He has been fourteen years vice-president of the Sanitary Aid Association, and has been on the Commission of the Peace since 1885. Dr. Croucher is the first Mayor of Hastings who has been elected from outside the

council.—The Mayoral chair of Bacup has been occupied on two previous occasions by Alderman W. J. CLEGG, M.D.—namely, in 1884–5 and 1885–6. A native of the town which has honoured him with this distinction, after receiving some slight instruction from his father he went to Paris, where he studied for some time previously to entering the University of Edinburgh, where he obtained the degree of M.D. and was first gold medallist.—GEORGE WRIGHT HUTCHINSON, M.D., who has been elected Mayor of Chipping Norton, is an ex-moderator (1878) of the General Assembly of the Church of Scotland and a J.P. for his county. Born Jan. 16th, 1848, he was privately educated, till two years before entering the University of Aberdeen, as an art student. Those two years were spent at the Grammar School, Aberdeen. Dr. Hutchinson entered the University of Aberdeen in October, 1863, and in May, 1865, commenced his medical studies, which were continued there till April, 1869, when he graduated Bachelor of Medicine and Master in Surgery (at Aberdeen) with academical distinction in April, 1869. In May, 1869, he succeeded Professor Mackendrick of Glasgow as resident and acting surgeon to Belford Hospital, Fort William, Inverness-shire. Here he remained for three years and a half. In January, 1873, he went to Chipping Norton, where he has since remained. Till June of this year he has always declined municipal life, but in that month he was returned at a by-election by an overwhelming majority.—Lymington has again chosen for its representative in the civic chair a descendant of one of the oldest Cornish families, Dr. W. ROBINSON HILL, who was born at Stonehouse, near Plymouth. He studied medicine in the University of Edinburgh, and was twice President of the Royal Medical Society. At the Royal Infirmary he acted as house surgeon under Dr. Gillespie. After occupying the position for one year of resident physician to the Brompton Hospital for Consumption, he went to the Berlin University and afterwards to the Paris hospitals.—REGINALD W. LATIMER GREEN, L.R.C.P. and L.R.C.S. Edin., who was last year elected by the burgesses of Stratford-on-Avon to the mayoralty, has again been chosen by them to occupy the civic chair. After being educated at Queen's College, Belfast, and Edinburgh, he commenced practice at Stratford-on-Avon in May, 1880, where three years after he was elected surgeon to Stratford-on-Avon Hospital and surgeon to the Provident Medical Institution.—The Mayor of Louth, PALEMON BEST, M.B. Lond., J.P. &c., was educated at Bath and Swansea, matriculating at University College, London, in 1858. Entering the College in the same year, he received his qualification in 1861. After taking his degree of M.B. in 1864 he went to Louth, and has for a quarter of a century taken a most active part in the welfare of the Louth municipality. St. Ives has chosen for its Mayor JOHN MICHAEL NICHOLLS, L.R.C.P. Lond., M.R.C.S., who studied at St. Bartholomew's Hospital and then went to Yeovil. Three years ago he was elected to the council and has recently been re-elected. Until his election to the civic chair he acted as chairman of the sanitary committee, and to his energy are due many of the sanitary improvements of the town.—J. M. HUGHES, M.B., M.S., who has been called to the office of Mayor for the town of Ruthin, was educated at Edinburgh University and graduated as M.B., C.M. in 1886. Although he has only resided in the district for six years, he has been twice returned at the head of the poll. Dr. Hughes is medical officer of health for the Ruthin Union Rural District.—N. W. FAIRLESS-HUMPHREYS, M.R.C.S., L.S.A., has for the fourth time been elected Mayor of Montgomery.—Crews has chosen for its representative in the civic chair WILLIAM HODSON, L.F.P.S. Glas., L.R.C.P. Irel., and Alderman J. P. ATKINSON, M.D., L.R.C.P., has accepted the Mayoralty of Saffron Walden.

## ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

ACCORDING to the twenty-first annual report of the Local Government Board the number of medical officers of health a moiety of whose salaries was repaid out of the county funds in 1891 was 1291, the corresponding number of inspectors of nuisances being 1236, whilst the total number of sanitary districts in England and Wales was 1586. The ratio of in-door paupers to every thousand inhabitants in the

provinces varied last year from 7.6 in Sussex to 3.7 in the West Riding of Yorkshire, and 3.3 in South Wales; the corresponding ratio as regards out-door paupers varying from 39.2 in Norfolk to 11.7 in Lancashire. In London the percentages were 14.5 as regards in-door and 11.3 as regards out-door paupers. Amongst the diseases received into the hospitals of the Metropolitan Asylums Board were 5262 cases of scarlet fever, 1313 of diphtheria, 755 of enteric fever and 64 of small-pox. Apart from improvement schemes, loans to the amount of nearly three millions sterling were sanctioned for sanitary purposes in urban districts and for £175,862 in rural districts; the loans for improvement of dwelling accommodation reaching nearly £118,000, besides other loans for over £65,000. These amounts are quite irrespective of large sums that can be raised under powers granted by special Acts of Parliament. Amongst defaulting authorities we find that Newbury, having had six months in which to perform its duty as regards sewerage, has since submitted a scheme for that work. The local board of Staines and the rural sanitary district of Staines have been dealt with in a similar way, and it yet remains to be seen what the result will be as regards both of them. Borstal, near Rochester, and Wetherby, in Yorkshire, have also had six months given to them in which to decide on a method of sewerage. In three cases the Board also gave their consent to proceedings being taken against manufacturers under the Rivers Pollution Prevention Act, 1876. According to the report of Mr. Brydone, the canal boats inspector, it is evident that the condition of the canal boat population is undergoing continuous and steady improvement, the former indecent herding of men, women and children is almost unknown, and the general sanitary state of the boats has much improved.

Under the Sale of Foods and Drugs Acts 29,028 analyses were made, this number exhibiting an increase of about 1600 on the previous year, the analyses amounting to one for every 580 persons in the metropolis and 1 for every 1140 in the provinces. But none at all were made in the parish of St. Martin's-in-the-Fields, none in four administrative counties and none in twenty-seven boroughs; indeed it is surprising that in so many populous and important districts the inhabitants choose, by the election of representatives opposed to the performance of their duty in this respect, to be left altogether without any protection against fraud in the sale of adulterated foods. Then, again, the average penalty was only £1 11s. 3d., and it must be obvious that this cannot be deterrent in the case of so remunerative a fraud as that of adulteration. In no less than 1242 cases the fines were of £1 or under. The largest number of samples examined consisted of milk. These were 12,151 in number, and in 13.4 per cent. adulteration had taken place. This exhibits a slight increase on the 12.8 per cent. of last year; but if we take the last three quinquennial periods milk adulteration has been found to diminish from 21.1 to 16.7, and again to 13.2 per cent. of the samples in the respective periods. Butter was found to be adulterated in 15.5, coffee in 17.0, spirits in 19.1, and drugs in 16.4 per cent. of the samples examined. Altogether rather more than 12 per cent. of the total articles of all sorts examined were found to be adulterated. Unfortunately, the practice of adulteration has become a fine art, new methods spring up as the grosser ones are detected, and it behoves public analysts to keep themselves versed in the new devices that are practised. In London the amount of milk adulteration reaches the highest standard, but there are especially gross cases in some provincial towns. Thus in Sheffield the amount of water added in one case amounted to 48 per cent., and the writer of this part of the official report pithily indicates the meaning of such an adulteration by pointing out that an addition of even 10 per cent. of water, which is probably less than the average, enables a dishonest milkman to keep ten cows instead of eleven.

In 1881 the percentage of births not finally accounted for in London as to vaccination was 5.7, since then it has gradually increased until it amounted in 1889 to 11.6, the rates varying from 25.1 in St. Giles's to 2.8 in Whitechapel, the two extremes involving districts in both of which many of the poorer inhabitants of the metropolis reside. The demands on the calf-lymph station are increasing. Last year 7687 children were vaccinated there, besides 350 persons who came for revaccination. The towns and districts now having compulsory notification of infectious diseases contain a population of 12,491,933, and Leeds remains the only really large borough which has not adopted the system. There are, however, other boroughs of over 25,000 which are in the same

condition—namely, Aberdare, Crewe, Doncaster, Dudley, Gateshead, Lincoln, Luton, Tipton, Walton-on-the-Hill, West Derby, Wednesbury and Ystradyfodwg. Nearly all these places are known to have grave sanitary faults. A separate report on the past year will, as usual, be prepared by the medical officer to the Board.

## THE MANCHESTER LIFE TABLE.

THE Manchester Corporation and their medical officer of health, Dr. Tatham, have, by the construction and publication of the Manchester Life Table, not only thrown a searching light upon the health condition of New Manchester, but have conferred a distinct boon upon all who are interested in the vital statistics of large towns.

It is as nearly as possible fifty years since Dr. William Farr, in the Registrar-General's seventh annual report, published an outline life table for Manchester, which showed that the expectation of life at birth in the Manchester of that day was only twenty-four years, and was sixteen years less than the mean expectation of life at birth in England and Wales. Since that time, although Manchester has, like the rest of England and Wales, experienced a considerable reduction in its death-rate, its excess of mortality has continued to attract much local and public notice. Many attempts have been made in recent years to discredit the value of a death-rate as a test of sanitary condition. These attempts have been mainly based upon an imperfect knowledge of the nature and extent of the disturbing elements of age and sex distribution and of the true import of varying birth-rates. Dr. Farr clearly pointed out years ago within what comparatively small limits the crude death-rate of a population might be absolutely trusted as a health meter, and how, by the construction of a life table, nearly all disturbing elements might be eliminated. When Dr. Tatham a year or two since was appointed medical officer of health for Manchester he appears very wisely to have determined that so soon as the new census supplied him with the necessary data concerning the number, sex and age of the population, he would construct a life table for the city. This resolution was probably strengthened by the persistent assertion that the high death-rates of the city were not due to insanitary condition, but to fallacious statistics.

Dr. Tatham's Life Table just issued is based upon the population of the three unions or registration districts of Manchester, Chorlton and Prestwich enumerated at the censuses in 1881 and 1891 and upon the 135,582 deaths registered within this area in the ten years 1881-90. As the population of this area increased from 528,307 in 1881 to 594,502 in 1891, it follows that the life table is based upon the recorded mortality during more than five million years of life, a basis sufficiently large to yield thoroughly trustworthy results. It is pointed out by Dr. Tatham that this area is somewhat larger than that of the city of Manchester, as extended by the Act of 1890, but may be taken as representing the enlarged city with sufficient approximation. The Manchester Life Table therefore gives the life history of a complete generation of 100,000 persons exposed at each successive age to the varying rates of mortality that prevailed within the above-mentioned area during the ten years 1881-90. It is scarcely necessary to point out that the results of this Life Table are far less unfavourable than they would have been if it had been based upon the statistics of the far smaller, more central, and more densely populated area of the city previous to the large extension of 1890. Still more unfavourable would the table have been if it had been constructed, as was Dr. Farr's table, referred to above, from the mortality experience of Old Manchester, or the Manchester registration district. Of New or Greater Manchester the table gives an accurate and incontestable measure of health and a sound standard for testing its sanitary progress during the new decennium which commenced with 1891.

Dr. Tatham, in his preface, acknowledges the assistance he has received in the mathematical part of the work from Mr. A. C. Waters of the Registrar-General's Department, and it is impossible to speak too highly of its method and of the arrangement of its tables. We should have liked to see included in the tables the rates of mortality per 1000 at successive ages and age periods, but the means are given for supplying this additional information. The full and careful

description of the principles and methods adopted in the construction of the Life Table will be found very valuable by medical officers of health of other large towns who are disposed to follow the excellent example set them by Dr. Tatham by constructing life tables for the populations under their charge.

We must now, however, proceed to notice a few of the more salient points in connexion with the health of Manchester which have been brought to light by this Life Table. The most important results of a life table may be said to be crystallised in the mean duration of life (or expectation of life at birth) which it shows. The Manchester Life Table shows that, based on the mortality experienced in Manchester during the ten years 1881-90, the mean duration of life of the Manchester population is 36.6 years, or 34.7 years for males and 38.4 for females. Compared with Dr. Farr's English Life Table (1838-54), the mean duration of life of persons of both sexes in Manchester is too short by 4.3 years; whereas, compared with Dr. Ogle's more recent table (1871-80), life in Manchester is shortened by 6.4 years. Male life in Manchester is shorter by 5.2 and 6.6 years respectively than the English means shown by the 1838-54 and 1871-80 tables; the defect of life among Manchester females, compared with the same tables, is 3.4 and 6.2 years respectively. It is scarcely necessary to point out that when the completion and publication of the census tables make it possible to construct a new English Life Table for the ten years 1881-90, the mean duration of life in England will be found to have considerably increased, and therefore the loss of lifetime in Manchester is undoubtedly understated by the figures given above. On the other hand, it should be noted that Manchester, as one of the very largest English towns, might not unreasonably claim comparison of its mortality statistics with those of other large towns rather than with those of the whole of England and Wales. It is, however, so far as we are aware, a fact that the Life Table now under notice is the first that has been constructed in recent times for any large English town.

Returning to the results of Dr. Tatham's table, it is interesting to note that the recorded mean annual death-rate in the area taken to represent New Manchester during the ten years 1881-90 was 24.2 per 1000, whereas in the hypothetical stationary life-table population the rate is shown to be 27.4 per 1000. This difference is entirely due to the abnormal age distribution of the real Manchester population, which contains an excessive proportion of persons at the ages when mortality is low, due partly to the excess of births over deaths and partly to the immigration of young adults. Of 100 born in Manchester only 21 live to the age of 65, whereas according to the general English table 31 out of 100 born survive to this age. Dr. Tatham calls attention to a feature of his life table, which points conclusively to the favourable effect of the rural immigration into towns upon the mortality at certain ages. Of 100 born in England and Wales 74 survive to complete their fifth year, while the survivors to this age in Manchester are but 70 out of 100; during the age period, 5-15, the probability of surviving is, however, almost as great in Manchester as in England and Wales generally; and in the next period, 15-25, the probability of survival is distinctly greater by the Manchester table than by the general English table. Dr. Tatham points out that these facts appear to "lend some colour to the suggestion that the effect of the greater mortality among young children is to weed out the more feeble, so that those who reach maturity shall be selected lives," but he proceeds to show that as, at all subsequent ages, the excess of mortality in Manchester reappears with increasing intensity, it seems impossible to doubt that the low Manchester death-rate between the ages of ten and twenty-five is due to the large immigration of selected lives at these ages. It is, moreover, obvious that the mortality at these ages recorded in towns understates the real mortality, since town immigrants frequently return to their rural homes in case of serious illness or disablement. If the Manchester table can be taken as typical in its general features of what the life-table statistics for other large English towns would be, which there seems no reason to doubt, then the heaviest life-tax in urban populations is in early childhood and between forty-five and sixty-five years of age, when the stress of urban residence seems to have most fatal effect.

Space will permit us to refer to only one more of the many practically useful deductions which Dr. Tatham draws from his Life Table. The ordinary life table shows how many of a certain number born survive to each year of age, and also the expectation of life at each age. This in-

formation, however, as Dr. Tatham points out, gives no indication of the relative working capacity of different populations. In other words, we want as evidence of true sanitary condition further information to enable us to estimate the proportion of a living population that is endowed with health and working capacity. It may be safely assumed that in Manchester, beyond the loss of lifetime due to the high death-rate, there is a further loss of working capacity among the survivors due to a higher sickness rate than that which prevails generally in England and Wales. Dr. Tatham points out how the Manchester Life Table may be said to show the lower vitality of the living population of Manchester compared with that of the whole country. According to the English Life Table the expectation of life among males at the age of 65 years is 10.8 years, whereas in Manchester it is necessary to go back to the age of 58½ years to find an expectation of life equal to 10.8 years. Further, the probability of a male in England and Wales aged sixty-five years living a year is 0.95,409; while in Manchester 0.95409 is slightly above the probability of a male aged fifty-seven living a year. Dr. Tatham seems, therefore, justified in asserting, on the strength of his table, that the vitality of males aged between fifty-seven and fifty-eight and a half in Manchester does not exceed that of males aged sixty-five years in England and Wales.

These are some of the more important deductions that may be made from this Manchester Life Table, which derives much of its interest from the fact of its being the first modern life table for a large English town. We venture to hope that the medical officers of some of the other large towns will follow Dr. Tatham's example, since the possibility of a comparison between two or three urban life tables would throw valuable light upon one or two of the most interesting features of the Manchester table, and would add considerably to our knowledge of the true import of the vitality and mortality statistics of our large towns.

## THE PRISON REPORTS.

THE reports annually made to the Home Department by the Prison Commissioners and the Directors of Convict Prisons are usually worthy of serious attention and on the present occasion derive even more than their ordinary interest from the circumstance that the course of recent discussion has led the compilers to address themselves specially to the inferences which are to be drawn from the statistics which they present. Some doubt has by recent writers been thrown upon the view, which we are all very willing to accept, that the great diminution of the prison population which has been so marked a feature of the reports of recent years is attributable to a lessening of crime. It has been argued that changes in our way of dealing with criminals rather than a change in the amount or character of crime afford the explanation of what is, on the face of it, a most beneficial change in our social condition. The view of Sir Edmund Du Cane and his colleagues does not bear out this pessimist contention. On the contrary, these authorities consider that the long-continued tendency towards a diminution of numbers which the prison population is manifesting in a very remarkable degree at the present time is indicative of an amelioration in manners rather than in laws. They attribute it mainly to the successful operation of remedial agencies by which the novice in crime is reclaimed from evil courses, and prevented from developing into the habitual criminal. It is, from our point of view, eminently satisfactory to receive such a testimony to the success of remedial treatment, and to have its value brought home to the public mind in this way. Popular ideas as to the ends of criminal justice are apt to be very confused, and in the past especially a just indignation at the iniquity of crime has been too much the animating temper of the Legislature in its dealings with the criminal. Of late more enlightened views have begun to prevail, and crime has been considered in its character as a social problem no less than in that of a public peril. The passion which inspires a lynching mob has given way to a more reflective temper, and it has been found that there are ways more excellent of dealing with a criminal than it is given to a mob to discover. No doubt there exists at the present time a large number of cases which can only be classed as morally incurable, but that is in no small degree the vice of imperfect methods. The remedial treat-

ment of criminals is a subject far, as yet, from having been worked out, and it should occasion no surprise if in this, as in other matters, we have to pick our way by slow and devious steps to a full understanding of the subject. That progress is likely to be of this character we have very specific warning in these pages from a prison chaplain whose observations are quoted in the Commissioners' report and who remarks that "there is an overlapping of labour in rescue effort which is acting very perniciously to the work generally and to the interest of the fallen woman individually. With such contentions for her case and with such notice as she is at present receiving, she is beginning to look upon herself not as a penitent, but as a person of a certain value for philanthropic advertisement." Errors so palpable as this will no doubt be soon corrected. The important point to be gained is that the problem of suppressing crime should be identified with that of reclaiming the criminal, and that mere sentiment, whether of indignation at the crime or compassion for the criminal, should come to be regarded as irrelevant in this connexion—as irrelevant as in the discussion of figures or of facts. How much may be learnt by mere observation carefully and systematically carried out is suggested, and to some extent illustrated, by the brief but significant remark which the Commissioners make that "Idleness is the offence which most commonly leads to punishment while in prison, as it is probably the cause of most of the offenders being there at all." Another inquiry of no less importance which is suggested and to some small extent perhaps advanced by the present report is that into the obscure and intricate relation between drink and crime. Many people are convinced that the relation is a simple one—that, namely, of cause and effect; but this has never yet been proved. Drunkenness and crime go hand in hand, but the very interesting diagrams which this report contains of the growth and prevalence of these two forms of vice over a series of years cannot fail to suggest to those who study them that the true relation between drink and crime is at the present time a matter to be investigated rather than to be explained.

## THE FIFTH CONGRESS OF ITALIAN MEDICINE.

UNLIKE its predecessors, this gathering had a special significance, that of being in some measure a rehearsal of the great International Congress which will meet in Rome on Sept. 24th, 1893. Dr. Baccelli opened the proceedings in the Aula Magna of the Roman University, and his short address was to the following effect:—

"Next year, as you all know, Rome will be the seat of the Eleventh International Congress of Medicine and Surgery. This fact obliges us more than ever to close up the ranks and to perfect the discipline of our medical forces, in order that the sittings of that Congress may issue honourably and be of good omen for the Italian name. The question which dominates every other is of a clinico-hygienic character—the study, to wit, of infectious maladies and the best means of combating them. Of many of these diseases the nosographic work is almost complete, of several the nosogenic work is well advanced, while there is wanting to all the 'posology' of infections or the determination and action of the toxic substances which are bred in human organisms by the action of pathogenic micro-organisms or by the reaction of the elements that compose the tissues. Arduous is the undertaking beyond all precedent. But here also the inductions of the clinical ward precede the studies of the laboratory and yield us a measure of moral certainty, while the irrefragable proof, which is always that by experimentation, will be furnished us if we sedulously labour in observance of the rubric of the ancient academy of research—"testing and re-testing." The clinique and the laboratory ought to march hand in hand with perfect harmony. The one represents the treasury of the experience of centuries, the other the conquests of to-day. It is only error which we ought to combat, but we have no right to demolish or to substitute at will for the sake of novelty. We must know profoundly the history, the circumstances and the arduous progress of the medical idea. We must be just with all, and above all we must be logical. Conceding the honours of the day to the study of infectious diseases, we must not lose sight of the scientific and professional (*artistica*) ground already gained. Nay, we must

perfect it with time and ever maintain burning the sacred fire of research. Not every Italian study, honourably known to history and to fame, is adequately appreciated by our brethren beyond the Alps and beyond the seas. It is our duty to diffuse the knowledge of such and to redemocratise it, if credited to another, by opportune vindication. Let us never lose sight of the fact that if science can give us great and ardently longed-for satisfactions, practice is what, in the social order, diffuses the prestige of our service. Between a true remedy and a conquest of science, suffering humanity will give the palm to the former. The solitary satisfaction of the soul belongs to pure mathematics; we can always keep ourselves mindful of the fact that 'nisi utile est quod facimus, stulta est gloria' (unless our work be useful, the glory of it is foolish). Gentlemen, an illustrious clinician, a noble intellect, endowed with varied and profound culture, Cesare Federici, is no more. To him be the honour and the regrets which are his due. But the most fervid and sincere prayers are invoked for our Arnaldo Cantani, that his lofty intellect and profound goodness of heart may soon be restored to him, and through him to us, so that he may live to be one of the strenuous champions in these encounters of the Italian professional arena. There is one in Italy who is always foremost wherever a disaster or a joy saddens or exhilarates the heart of the nation. This one has authorised me to announce to you that 'he will inaugurate in person the International Congress.' To him be, therefore, our gratitude. Let a new emblem of scientific and professional greatness be the name of Humbert."

The discourse, delivered with characteristic *brío*, was loudly applauded, after which the Congress settled down to the agenda paper. Professor Forlanini read his "Velazione" on *Xerotherapy*, which occupied the rest of the forenoon; and in the afternoon Dr. Baccelli commented on some peculiarities of the blood and urine of malarious subjects, followed by an elaborate memoir of Professor Maragliano of Genoa entitled "Sull' Azione Alterante del Siero del Sangue Patologico sulle Emazie" (*alvariai*). The subsequent sittings of the Congress included papers and discussions, such as those of Professor Lombroso on the Character of Born Delinquents or Moral Maniacs and on their Analogies with Epileptics; of Professor Rummo on Paraplegia Spastica Congenitalis; of Professor Riva on Rheumatic Infection; and of well-known clinicians and consultants such as Ferletti, Cavallero, Castellino, Sansoni, Masini, Borgherini, Caffarelli, Giuffrè, Lipari, Spallieci and others. The proceedings terminated with a banquet, at which Dr. Baccelli took the chair; while the scientific outcome of the Congress will be found officially embodied in the "Atti," as revised by the authors of the several papers and by the critics who followed.

Rome, Nov. 1st.

## BOLINGBROKE HOUSE.

ON the 11th inst., at St. Mark's Vestry Hall, Battersea Rise, a meeting was held for the purpose of calling public attention to the financial difficulties of the above institution, and to make better known the objects of the hospital. Bolingbroke House will afford "a home in sickness for those who need the advantages of hospital treatment and nursing and are able to pay wholly or partially for the same." Lord Battersea, who presided, said he was surprised that the hospital was so little known. There were many people who could not afford to have operations performed at their own homes and who did not care to be the recipients of hospital charity, willing to pay the sum of two or three guineas per week if they only knew of the existence of such an institution as Bolingbroke House. This was practically the first hospital to adopt the system of "paying patients," which had been adopted by many other institutions; but Bolingbroke House supplied luxuries and comforts which could not be obtained elsewhere. He hoped that the public would freely subscribe to the good work that was being done, and that the work would not be stopped for the want of a few pounds.

Sir Henry Peek, Bart., proposed the following resolution, which was seconded by Mr. Oram, who emphasised the fact that the institution was in reality not a hospital, but a "home": "That the work which has been done at Bolingbroke House in the past twelve years, during which time 1200 patients have been received in addition to much assistance given in emergency cases, has been a great public

benefit, especially to this neighbourhood, and shows the urgent necessity for the maintenance and development of the hospital."

The Hon. Conrad Dillon, in submitting a resolution to the effect that, "although those patients who have paid only a proportion of their cost have contributed according to their means, the receipts have fallen short of the expenditure and prevented the hospital from being self-supporting, and therefore it is expedient that a sum of at least £2000 should be raised forthwith to prevent its being closed," spoke of the energetic labours of Canon Erskine Clarke, who had founded the hospital and who had for the past twelve years supplied the funds. He said that the finances were now in such a state that if the hospital were to cease its work to-morrow they would be exactly solvent.

Both resolutions being carried, Mr. T. Bryant, President of the Royal College of Surgeons, testified to the excellence of the hospital arrangements. In all nearly 200 large operations had been performed with very little mortality, and this he attributed to the airy wards, good nursing and good food.

The meeting having recorded its appreciation of the services of the committee of management and the staff in carrying on the institution, a vote of thanks to Lord Battersea terminated the proceedings.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6375 births and 3817 deaths were registered during the week ending Nov. 12th. The annual rate of mortality in these towns, which had increased from 17.3 to 19.6 per 1000 in the preceding four weeks, declined to 19.5 last week. In London the death-rate was 18.8 per 1000, while it averaged 20.1 in the thirty-two provincial towns. The lowest rates in these towns were 13.0 in Leicester, 13.1 in Wolverhampton, 15.2 in Norwich, and 16.1 in Derby; the highest rates were 25.1 in Bolton, 26.7 in Hull, 28.0 in Salford, and 29.6 in Preston. The 3817 deaths included 434 which were referred to the principal zymotic diseases, against 407 and 434 in the preceding two weeks; of these, 139 resulted from measles, 81 from diphtheria, 74 from scarlet fever, 55 from whooping-cough, 46 from diarrhoea, 34 from "fever" (principally enteric), and five from small-pox. These diseases caused the lowest death-rates last week in Derby, Halifax and Norwich, and the highest rates in Plymouth, Hull, Croydon, Preston and Salford. The greatest mortality from measles occurred in West Ham, Oldham, Brighton, Croydon, Portsmouth, Hull and Salford; from scarlet fever in Croydon, Cardiff, Plymouth, Salford and Preston; from whooping-cough in Croydon, Salford and Preston; from "fever" in Portsmouth, Birkenhead and Wolverhampton; and from diarrhoea in Preston, Leicester and Oldham. The 81 deaths from diphtheria included 51 in London, 4 in Sheffield, 3 in Cardiff, 3 in Manchester and 3 in Leeds. Three fatal cases of small-pox were registered in Sheffield, one in Halifax and one in Huddersfield, but not one in London or in any other of the thirty-three large towns; 3 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 2 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 4063, against 3936, 4012 and 4067 on the preceding three Saturdays; 403 new cases were admitted during the week, against 410 and 462 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 267, 296 and 319 in the preceding three weeks, further rose last week to 357, but were 39 below the corrected average. The causes of 75, or 2.0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Bolton, Preston, Newcastle-upon-Tyne, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Leicester, Liverpool and Sheffield.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the largest Scotch towns, which had increased from 19.0 to 22.9 per 1000 in the

preceding three weeks, declined again to 20.6 during the week ending Nov. 12th, but exceeded by 1.1 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14.5 in Paisley and 14.9 in Greenock to 22.4 in Glasgow and 26.0 in Leith. The 574 deaths in these towns included 61 which were referred to measles, 19 to scarlet fever, 9 to whooping-cough, 9 to "fever," 6 to diarrhoea, 5 to diphtheria, and one to small-pox. In all, 110 deaths resulted from these principal zymotic diseases, against 80 and 108 in the preceding two weeks. These 110 deaths were equal to an annual rate of 4.0 per 1000, which exceeded by 1.8 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased in the preceding seven weeks from 12 to 69, declined last week to 61, of which 23 occurred in Edinburgh, 19 in Aberdeen, 11 in Leith, and 7 in Glasgow. The deaths referred to scarlet fever, which had been 14 and 13 in the preceding two weeks, rose again last week to 19, and included 14 in Glasgow, 3 in Edinburgh, and 2 in Leith. The 9 fatal cases of whooping-cough exceeded by 4 the number in the preceding week, and included 8 in Glasgow. The deaths referred to different forms of "fever" which had been 2 and 5 in the previous two weeks, further rose to 9 last week, of which 6 occurred in Glasgow. The 5 fatal cases of diphtheria showed a marked further decline from those recorded in recent weeks, and included 2 in Edinburgh and 2 in Glasgow. The death from small-pox was registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 138 and 142 in the preceding two weeks, were again 142 last week, and were 120 below the number in the corresponding period of last year. The causes of 63, or nearly 11 per cent., of the deaths in the eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased from 19.4 to 28.5 per 1000 in the preceding three weeks, declined again to 23.9 during the week ending Nov. 12th. During the first six weeks of the current quarter the death-rate in the city averaged 23.1 per 1000, against 17.8 in London and 21.6 in Edinburgh. The 160 deaths in Dublin during the week under notice included 5 which were referred to different forms of "fever," 2 to measles, 2 to diarrhoea, and not one either to small-pox, scarlet fever, diphtheria or whooping-cough. In all, 9 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.3 per 1000, the zymotic death-rate during the same period being 1.8 in London and 5.7 in Edinburgh. The deaths referred to different forms of "fever," which had increased from 2 to 10 in the preceding three weeks, declined again to 5 during the week under notice. The 2 fatal cases of measles exceeded the number recorded in any recent week. The 160 deaths registered in Dublin last week included 25 of infants under one year of age and 45 of persons aged upwards of sixty years; the deaths of infants showed a marked decline, while those of elderly persons showed a further increase upon those recorded in recent weeks. Six inquest cases and 4 deaths from violence were registered; and 41, or rather more than a fourth of the deaths, occurred in public institutions. The causes of 19, or nearly 12 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

### MOVEMENTS OF MEDICAL STAFF.

SURGEON-COLONEL JAMESON has re-embarked for Egypt on return from sick leave of absence. Brigade-Surgeon-Lieutenant-Colonel Comerford has arrived in Bermuda and assumed the duties of Senior Medical Officer. Brigade-Surgeon-Lieutenant-Colonel Scott has embarked for India on a tour of foreign service, and Brigade-Surgeon-Lieutenant-Colonel Barrett, whose promotion was recently gazetted, has arrived home in the *Tamar* on completion of a tour. Surgeon-Captains Lynden Bell and Gubbin have arrived at Bermuda for duty, and Surgeon-Captain Reilly has obtained leave from there. The following officers have embarked for India in the *Crocodile*:—Surgeon-Captains Tate, Watson, Mummy, Brogden, Birch and Kelly. Surgeon-Captain Carr has arrived home in the *Serapis*. Surgeon-Captain Risk has

been posted to Aldershot, and Surgeon-Major Drury has obtained sick leave from that station. Surgeon-Captain Barton has rejoined at Holme. The death of Surgeon-Captain Waller has been reported from Bengal.

#### ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel John Ross Murray, M.D., F.R.C.S. Edin., has been placed on retired pay.

#### ARMY VETERINARY SCHOOL.

Veterinary-Captain Scaward Longhurst, Army Veterinary Department, has been appointed Professor, vice Veterinary-Captain Fred Smith, whose period of service in that appointment is about to expire.

#### INDIAN MEDICAL SERVICE.

The following appointments have been made:—Surgeon-Captain A. H. Nott, Officiating Second Resident Surgeon of the Presidency General Hospital, to act as Civil Surgeon of Birbhum. Surgeon-Captain B. D. Basu, I.M.S., has been transferred from general duty, Scinde District, to general duty, Bombay, Deesa, and Aden Districts. Brigade-Surgeon-Lieutenant-Colonel R. P. Ferguson, A.M.S., having been appointed an Army Medical Officer in the Bengal Command, has been directed to proceed to Allahabad in order to take over the administrative medical charge of that district. Surgeon-Major B. Doyle has been posted to Ferozepore. Mr. H. A. Hall and Surgeon-Lieutenant-Colonel S. M. Salaman, M.D., have respectively delivered over and received charge of the Yerrowda Central Gaol. Surgeon-Captain A. V. Anderson, M.B., has been appointed to act as Deputy Sanitary Commissioner for the Western Registration District. The following promotions are made subject to Her Majesty's approval:—To be Surgeon-Lieutenant-Colonel from Oct. 1st, 1892: Surgeon-Major A. N. Rogers-Harrison, M. P. L. Beech, and H. P. Esmonde-White. To be Surgeon-Majors from Oct. 2nd, 1892: Surgeon-Captain J. L. Van Geysel, H. N. V. Harington, G. M. F. McKee, J. A. F. Burton, and F. J. Doyle.

#### NAVAL MEDICAL SERVICE.

The following appointments have been made:—Fleet Surgeon J. Lyon, M.D., to the *Impregnable*. Staff Surgeons: T. E. H. Williams to the *Pelican* and G. F. Watts to the *Beagle*. Surgeons: William R. M. Young to the *Wildfire*, for Sheerness Dockyard; R. Hickson to the Bermuda Hospital; O. S. Fisher to the *Alaric*; J. Lowney to the *Redpole*; E. E. P. Tindall to the *Plover*; E. C. Lomas, M.B., to the *Pigmy*; J. Dawson to the *Pembroke*; B. S. Mends, to the Portsmouth Division, R.M.A.; A. Kidd to the *Caroline*; E. E. Bray to the *Mercury*; E. J. Swan to the *Archer*; F. W. Parker to the *Cambridge*; and E. A. Shaw, B.A., M.B., to the *Hearty*.

#### VOLUNTEER CORPS.

*Artillery*: 2nd Hampshire (Southern Division Royal Artillery): Surgeon-Captain B. J. Guillemard, M.D., has resigned his commission. The Volunteer Officers' decoration has been conferred upon the following:—Surgeon-Lieutenant-Colonel Thomas Henry Moxon, 1st Norfolk Artillery; Brigade-Surgeon-Lieutenant-Colonel Stephen Moulton Hopson, 3rd Volunteer Battalion, the Norfolk Regiment; Brigade-Surgeon-Lieutenant-Colonel Geo. Sampson Elliston, 1st Volunteer Battalion, the Suffolk Regiment; Surgeon and Honorary Surgeon-Major John William Harper, retired, 2nd Volunteer Battalion, the Suffolk Regiment; Surgeon-Major Daniel Bailey Balding, 1st (Hertfordshire) Volunteer Battalion, the Bedfordshire Regiment; Surgeon-Major (ranking as Lieutenant-Colonel) Alfred T. Brett, M.D., retired, 2nd (Hertfordshire) Volunteer Battalion, the Bedfordshire Regiment; Honorary Assistant Surgeon William Gimson, M.D., retired, 3rd Volunteer Battalion, the Bedfordshire Regiment; Surgeon and Honorary Surgeon-Major Theophilus Wm. Trend, M.D., retired, 2nd Volunteer Battalion, the Hampshire Regiment; Brigade-Surgeon-Lieutenant-Colonel Henry Robert Smith and Surgeon and Honorary Surgeon-Major John Robert Kealy, M.D., retired, 3rd Volunteer Battalion, the Hampshire Regiment; Brigade-Surgeon-Lieutenant-Colonel Fredk. Fawson, Lee, M.B., 1st Wiltshire Rifle Volunteer Corps.—*Rifle*: 2nd (Westmorland) Volunteer Battalion, the Border Regiment: Surgeon-Lieutenant R. W. Leeming has resigned his commission.—4th Volunteer Battalion, the King's (Liverpool Regiment): Surgeon-Captain W. J. Fleetwood, M.D., has been appointed Surgeon-Major.

#### EXAMINATION.

A medical examination has been ordered by the War Office of candidates for the Royal Military College, Sandhurst, to

be held at the Offices, King-street, Westminster, on the 28th and 29th inst.

#### SICKNESS IN THE ROYAL WELSH FUSILIERS.

According to the Indian papers the Peshawur Valley has been very unhealthy this year. The Royal Welsh Fusiliers have lost many men during the hot weather and rains, and have a large number of sick in hospital with fever. The regiment is stated to be under orders for Nowshera. The whole valley is well known as a malarious locality, and the form of fever which occurs there has certain features which have given rise to the name of "Peshawur fever"; and it is alleged that the unusually heavy rains which occurred a few months ago gave rise to a considerable increase of that disease. Removal from the locality and complete change of climate is recognised as the only remedy where it is at all intractable and does not yield to treatment.

The usual "Report on the Sanitary Measures in India in 1890—91," for presentation to both Houses of Parliament has just been issued. It contains chapters on the health of the European and native, with which we have already dealt, on the health of prisoners in gaols and on that of the general population, together with chapters on medical institutions, including medical schools and lunatic asylums, and on sanitary works. Appended to the report are abstracts of reports by the Sanitary Commissioners in India, and memoranda by the Army Sanitary Commission in England. We hope soon to deal more fully with this blue-book.

## Correspondence.

"Audi alteram partem."

### THE BRADSHAW LECTURE.

To the Editors of THE LANCET.

SIRS,—Dr. Gee in his recent Bradshaw Lecture, which is published in the current number of THE LANCET, told us among other things that he had sometimes found the scalp in tuberculous meningitis too tender to bear shaving and commended this observation, among others, to the consideration of "those who find a difficulty in believing that leeches or blisters applied to the skin can possibly affect a deeply seated part with which the skin has no obvious connexion." I do not know whether Dr. Gee meant his admonition for me, or only whether the consciousness of coming within its scope made me suppose so; but when something is commended to my consideration by a person in a place of authority, and one whom I respect so much as Dr. Gee, it behoves me to give my respectful consideration to it. As it is not easy to say what is possible I will be content with what is probable, and I will deal in especial with the subject of meningitis, to which he has given prominence. The case stands thus, if I may try to expand Dr. Gee's statement of it without misrepresentation. The scalp may become tender in meningitis, though there is no obvious connexion between the seat of the tenderness and the seat of the disease; therefore I am to consider whether irritation of a neighbouring but unconnected surface may not act beneficially upon a subjacent region of inflammation. Now I deny the major and dissent from the conclusion which is implied. If the scalp become tender under meningitis I presume it is because the roots of the fifth nerve, which lie at the base of the brain, are irritated by the inflammatory products or the inflammatory condition there present, whereby the branches of the same nerve which go to the scalp are made hyperæsthetic. This appears to be simple enough, but I do not see how it bears upon counter-irritation or local bloodletting. Does it afford any ground to suppose that irritation of the scalp will influence the course of meningitis? At most it displays a sensory consent between the roots and the branches of the same nerve, a condition of which we have many other examples. If, by appealing to the branches of the fifth nerve, we could influence its roots, does it follow that we should thereby lessen the inflammation around them which is the cause of the irritation, not its consequence? As well might we hope to benefit a case of renal stone by applying remedies to the tender or painful testicle.

Thus stands the case when we have an obvious and intimate nervous connexion between the surface and the position of the inflammation below; but when I try to follow further the line of thought which Dr. Gee indicates, and to follow it in the direction of the tradition of counter-irritation, there I find myself lost in mystery. Because a deep inflammation affects painfully a nearly connected surface, does it follow that irritation of a surface will affect beneficially a remotely connected deep inflammation? Here, I confess, I fail to see my way. Is there some remedial sympathy between surfaces and organs dependent on propinquity rather than anatomy, which travels across country rather than by recognised routes? Some such fancy has guided the practice of generations, and even still has its influence. Shall we continue to blister the wall of the chest as exactly over a vomica or a mass of hepatisation as our diagnosis permits or the nape of the neck for any cerebral affection, even though it permits of no diagnosis? Such things have been done. I do not know whether Dr. Gee would carry his argument to these practical issues. He does not say so; for the sake of his patients I hope not. But he has commended to my consideration facts which appear to lead him in this direction, and I cannot do less than consider them.

I am, Sirs, yours truly,  
W. HOWSHIP DICKINSON.

Chesterfield-street, W., Nov. 14th, 1892.

### SMALL-POX IN LEICESTER.

To the Editors of THE LANCET.

SIRS,—Your impressive note of warning in THE LANCET of last week may possibly have some effect on the minds of those who are responsible for the present state of things at Leicester. Will you allow me to accentuate your remarks by stating facts within my own experience which may be worth recording?

In 1882 the same thing happened at Nottingham as that which has just taken place at Leicester. At that time a group of wooden sheds or huts was all that Nottingham possessed for the hospital isolation of scarlet fever and small-pox, both of which diseases prevailed concurrently, and both of which were required to be notified in accordance with the provisions of a local Act of Parliament. A patient in one of the scarlet-fever huts caught small-pox. Some were of opinion that infection took place across the open space which separated the huts; by others it was considered more likely to have been the consequence of a forbidden communication between the inmates of the scarlet-fever and small-pox huts. The mode of infection, however, was not the essential point, the fact of real importance being that a person who had been removed from home to the huts in order to prevent the spread of scarlet fever had been attacked with small-pox, owing to the proximity of the disease, whilst under the care of the municipal authority. After such an experience, I could not, as medical officer of health, allow any case of scarlet fever to be treated at the huts without personally satisfying myself that, by vaccination or revaccination (according to age and other circumstances), I had effectually guarded against the recurrence of so serious an accident. The town council of Nottingham set to work soon after to improve their defences against epidemics, and they now have one of the best isolation hospitals in England. It is surprising that Leicester should be so far behindhand in 1892.

I would take this opportunity of calling attention to other sources of danger for which the authorities of Leicester ought to be fully prepared. In a community where the proportion of the unvaccinated is increasing year by year, and where notification and isolation are mainly relied on for protection against small-pox, there must always be the danger of "unrecognised cases." A person passing through the disease in a slight, modified form, and able to go about as usual, may start an epidemic. An illustration of this has occurred within my own observation. Then there are the "doubtful cases" and those of "mistaken diagnosis," which should be provided for in anticipation. In the establishment of isolation hospitals, I have of late years urged very strongly the need for a sufficient number of detached "observation wards." I am afraid that Leicester is very badly equipped in this as in other essential respects.

I am, Sirs, yours obediently,  
EDWARD SEATON, M.D. Lond.

Clapham Common, S.W., Nov. 10th, 1892.

### "MEDICAL AID ASSOCIATIONS."

To the Editors of THE LANCET.

SIRS,—It has been said, Why may not the public coöperate and secure medical advice at coöperative prices? I cannot for a moment admit that the practice of medicine lends itself to this so-called coöperative method, for I believe the more deliberate the attempt to identify the science and art of medicine with a trade or business the more disastrous will be the result to the public. The profession and an ordinary trade, to which modern attempts are being made to reduce it, are as different in essentials and in the handling they require as are such diverse subjects as scientific discovery and galvanised iron bucket making. The identification will destroy the essential principles of our profession—it will destroy the incentive to excel. What, it may be asked, is the use of all our sanitary legislation and efforts to prolong life and reduce sickness if side by side we allow to grow up a system opposed to the essentials of good medical practice—a system which abolishes all incentive to good practice in our practitioners, who are daily fighting with disease and death—a system which all admit cannot but tend to produce perfunctory work, which, in medicine of all things, is synonymous with bad work? Does anyone doubt that these are the real results of a system of fixed wage-paid medical service? Is it necessary to particularise when speaking to an audience of medical men?

But let us examine a little more closely what our questioner means by "coöperative," and let us not confuse coöperation with combination. "Coöperation" is derived from *co* and *operari*, and thus signifies conjoint labour, not a mere combination or conspiracy to secure a certain end. In its general spirit it may be described as a theory of labour, and in its general aim as an industrial force. The only indispensable labourer in a Medical Aid Association is the doctor; it is his capital, in the form of skill, and his labour which alone create the wealth. Those who do not labour or contribute to the earning have no right to share the result of another's industry, and to call such a sharing coöperation is a contradiction in terms. Coöperation seeks to make and to retain wealth by taking into partnership those who, by their labour, create it. In Medical Aid Associations there are no such labourers other than the doctor. If it be said that the committee work, it may be properly replied, It is true they hold totally unnecessary meetings, but that is not productive labour. If those retain who do not earn, the scheme ceases to have any claim to be called coöperative, but it may fairly be classed as a combination to defraud. If it be said that the goodwill is supplied by the members and that this represents the capital of the business, it may properly be replied that this exploiting of medical skill and labour for profit by lay capital is one of the fundamental abuses of the system, a reform of which is demanded. A coöperative store is a coöperation of small capitalists to employ their own capital and to run their own business, which differs from the practice of medicine inasmuch as to do so does not require a licence. By so using their own capital they save the middleman's profit, and do not make their profit by underpaying their servants for the amount of work done. The saving is effected by interest on capital employed and not by taking part of the earnings of their workers. If Medical Aid Associations do anything they create the middleman; they certainly do not abolish him.

What is the economic position of a medical man? The labour of the doctor is indirectly productive by preserving or restoring the health and consequent power of work of the productive workers. Now, there can only be coöperation in this sphere of usefulness by a combination of medical labourers working together so that all may share in the result of their industry in proportion to the amount contributed. There can be no coöperation proper between one medical man and a large number of laymen; although it is manifest there can be a combination on the part of a number of laymen to transfer to their own pockets what is fairly and justly earned by and belongs to the medical worker. To regard such a combination as coöperation is, however, altogether fallacious. A well-known author on coöperation says: "Coöperation touches no man's fortune; it seeks no plunder; it causes no disturbance in society; it subverts no order; it has its hand in no man's pocket. It seeks its ends by means which leave every other person an equal chance of the same good." Let us see how this fits Medical Aid Associations. Now, in these businesses a profit may be

made in either of two ways: (1) the direct trade profit on the conduct of the business, or (2) the indirect, but not the less real, "saving" profit accruing to the individual members. This indirect profit is to be estimated by the money saved in fees as the result of the combination. For example, a man who is perfectly well able to pay and who does not deny his ability to pay the ordinary and fair charges of his medical adviser joins a Medical Aid Association. For an annual payment of 3s. 6d. he receives what formerly cost him £10. He is pecuniarily benefited to the extent of £9 16s. 6d. a year. But is this a defensible proceeding? Is this an allowable combination? Are the medical men to be condemned for protesting against what is, having regard to the foregoing considerations, clearly a robbery, even though effected under the cloak of a combination or association miscalled coöperative? A builder and contractor recently said: "What I formerly paid my doctor for one visit now pays my medical bill for a whole year." This kind of robbery is going on to a perfectly incredible extent at the present time. It is not denied that it is so; on the contrary, it is admitted, and it is openly claimed that the proceeding is legitimate. Let us imagine for a moment a parallel in the "Law." There are 100 wealthy men, each of whom pays to his respective solicitor charges for conveyancing and other professional work amounting to £100 a year. They combine, or, if the word is preferred, coöperate. They engage a solicitor as their wage-paid controlled servant and pay him a salary of £300 a year. Each of the hundred wealthy men contributes £3. What is the result of this pretty combination? The laymen save in the aggregate £9700. In other words, they have transferred to their own pockets £9700 which properly belongs to the legal profession. The profession is poorer by so much; while those who could well afford to pay, and for whom that amount of work has been done, have by their illicit and indefensible combination become so much the richer. The solicitor has been underpaid, having regard to the amount and value of the work done. Shall we call this coöperation? No; it is an illicit combination to indirectly enjoy the pecuniary benefits of a licence not possessed; for, as I have previously shown, the privilege of making a pecuniary profit out of the practice of law or medicine belongs exclusively to the licence, and without the licence the privilege does not exist. What would the Incorporated Law Society say to all this? That authority would say exactly what, I have no doubt, the General Medical Council will say to the analogous position in medicine: "This cannot be."

Here once more let me tell the tale of Stourport, for it well demonstrates this illicit combination to rob the doctors of their legitimate remuneration. The population of Stourport is 3504. The total number of members of the Medical Aid Association is 3177. That the scheme has but little of the friendly societies' element in it, of which we have heard so much, is shown by the fact that the club members number 591, while the public members amount to 2526. In other words, after providing for the medical wants of the members of the friendly societies, 2526 persons have combined to transfer to their own pockets (by saving) what fairly and honestly belongs to the medical profession. And who are these 2526 persons? In the Association there are or have been all the Dissenting ministers, one solicitor, four members of the local board, nine-tenths of the publicans and hotel-keepers, 50 per cent. of the tradesmen (including several large drapery houses), two jewellers, several butchers (some of these have their villa residences outside the town), all the coal merchants, many owners of house property, a large proportion of the farmers (many of them farm hundreds of acres—one as much as 1000 acres), and several estate owners.

In the Kidderminster Medical Aid Association there are 2272 club members and 2367 public members; in the Luton Friendly Societies' Medical Institute the club members contribute £322, while the public members' contributions yielded £512. These three examples—Stourport, Kidderminster and Luton—demonstrate a great abuse constituted by the departure from the original intention of Medical Aid Associations. They have developed from amalgamated clubs to immense private practices, the profits of which, either directly or indirectly, pass into the pockets of the unlicensed laity instead of into the pockets of the licensed practitioners who earn them.

I am, Sirs, yours truly,

LESLIE PHILLIPS,

Birmingham, Nov. 5th, 1892.

Hon. Sec., Medical Defence Union.

To the Editors of THE LANCET.

SIRS,—I am an old "Association" surgeon, but until reading the letter of "Verax" was unaware that any Utopia such as he seems to be dreaming of existed among the so-called "Medical Aid Societies." My experience, as likewise that of the many still under "the thrall of the committee" who write to the medical and lay journals, reduces the remarks of "Verax" to absurdity. The work in a "flourishing business" such as ours was is prodigious and altogether out of proportion to the salary—indeed, beyond the conception of the hardest-worked general practitioner. He is a lucky "Association" doctor who, in the stress of winter work or epidemic—influenza, to wit—has not to dip deeply into his meagre salary for "extra" cab hire; for, Sirs, we are dealing with patients far more exacting than those who pay a reasonable fee for attendance. When sent for, tired though we be both mentally and physically, we must go without murmur or be reported for negligence, and in due course "hustled" by the committee, who, generally speaking, have less knowledge of the feelings of a gentleman than we have of the canals in Mars. There is an old saying—and, like most of them, it is true—that "a man has either made or missed his mark at forty." In this category must be included those individuals of "mature years" who accept salaries of £50 or £70 per annum (in-door). When such as these apply there is a "screw loose." Short comment only is needed upon the remarks as to a "locum" holding a death vacancy for a time &c., as likewise those referring to "medical aids" taking patients from other practitioners—they stultify themselves. Reference is made by "Verax" to an association where a question arose as to an increase in salary of the medical officer after five years' service. Now, Sirs, from your leading article of the 15th inst., this can clearly apply to one town only, and having in view the pathetic platitudes of "Verax" as to his "injured feelings," caused by the said article, would it not have been more seemly and courteous had he made himself master of the facts (an easy matter, by the way) and surmised less as to the "market value" (save the mark!) of the services of the medical officer so directly indicated, whose susceptibilities may be as keen and feelings as "nice" as his own? The whole tone of "Verax's" letter makes one pause and think, Is it not a peripatetic pandering to a committee with which he is a trifle "off colour"? If so, I would advise him to be as I used to be with that under which I worked—

Oct. 25th, 1892.

"AUT CÆSAR, AUT NULLUS."

To the Editors of THE LANCET.

SIRS,—I would like to ask "Verax" if he considers the following description of how the midwifery department of the company's business is managed is conducive to professional dignity, or tends to elevate the public morals:— "The members' wives can secure the services of the Company's medical officer on payment of 10s. 6d. to the secretary." I presume that as the medical officer is not in any way consulted, the secretary obtains particulars on various delicate points. If it is found that the company's business in this department is at all slack, one of the committee is instructed to canvass the district, and invite the ladies to engage the services of their able medical officer, who being a married man with a large family, has considerable experience in this particular department. What I have detailed actually takes place.

I am, Sirs, yours truly,

L. R. C. P. Lond.

Nov. 7th, 1892.

"AMPUTATION FOR DIABETIC GANGRENE."

To the Editors of THE LANCET.

SIRS,—In your issue of Nov. 5th Mr. T. Davies Pryce refers to my paper on the above subject, read before the Royal Medical and Chirurgical Society on Oct. 25th, and draws attention to the fact that both atheroma of vessels and peripheral neuritis may be present in a case of diabetic gangrene, and may, apparently, both have something to do with its causation. I have no doubt that he is correct, and, indeed, endeavoured to bring out this point in my paper, but unfortunately omitted to do so in the abstract sent to the journals. I do not think that the presence of both these conditions need necessarily

be looked upon as an absolute contraindication to amputation, but rather that, whilst the presence of arterial degeneration makes the case much less promising, that of peripheral neuritis has not much to say to the matter. Gangrene starting from a perforating ulcer is a much more dangerous affection if the vessels be sclerosed than if they be healthy, but senile gangrene in a diabetic is not a more serious affection in a man with peripheral neuritis than in one without it.

I am, Sirs, yours faithfully,

RICKMAN J. GODLEE, F.R.C.S. Eng.

Wimpole-street, W., Nov. 11th, 1892.

### THE CLIFTON LUNACY CASE: MASON v. MARSHALL AND SHAW.

To the Editors of THE LANCET.

SIRS,—Upwards of four years ago you were kind enough to open your columns for a subscription-list towards defraying the expenses of Dr. Shaw and myself in defending the lunacy certificate action brought against us by Miss Mason. The result of the trial, your readers may remember, was a verdict with costs in our favour. At the time there appeared to be no probability of our obtaining costs; recently, however, they have been recovered, with the result that we have now a balance in our favour. My own legal expenses came to £304 13s. 6d., the taxed costs now recovered to £221 19s 7d., thereby reducing my legal expenses to £83 13s. 11d. From the treasurer (Dr. E. Long Fox) of the fund contributed by the medical profession I received £155 2s. 9d., which places a balance of £71 8s. 10d. at my disposal. I have been anxiously considering how best to apply this surplus amount in a way likely to prove most in accordance with the feelings and wishes of the donors to the fund, and, after consultation with Dr. Fox as their official representative and with other friends, I have decided to send a contribution of £100 to the Library of the Bristol Medical School. I trust that this will meet with the approval of those of my professional brethren who showed me so much sympathy, and gave such practical assistance at a time of great anxiety. The recollection of this sympathy and kindness remains gratefully and indelibly fixed in my memory, while the worries and vexations attendant on the trial are forgotten. Thanking you, Sirs, for your support,

I remain, Sirs, your obedient servant,  
Clifton, Nov. 14th, 1892. HENRY MARSHALL, M.D. Edin.

To the Editors of THE LANCET.

SIRS,—As a codicil to the letter from Dr. H. Marshall, will you allow me to add that, having also recovered my taxed costs from the plaintiff in the action brought against us, I have now received from all sources a surplus beyond my original expenses. With exceeding pleasure I have made a donation of £100 to the library of the new Bristol Medical School, and the small balance still remaining I am spending upon my wards in the Bristol Royal Infirmary. Deeply and increasingly grateful for the sympathy shown us at the time, it would not be honourable to profit by the generosity of our professional brethren, and I gladly, therefore, contribute to the equipment of an institution which at this moment is an appropriate object of pecuniary support.

I am, Sirs, yours faithfully,  
Bristol, Nov. 16th, 1892. J. E. SHAW.

### "THE RADICAL CURE OF FEMORAL HERNIA."

To the Editors of THE LANCET.

SIRS,—I have read with much interest Mr. Watson Cheyne's paper on the Radical Cure of Hernia published in THE LANCET of Nov. 5th. Since the autumn of 1888 I have performed the operation for the radical cure of femoral hernia as described by Mr. Watson Cheyne, with the exception that I have not thought it necessary to dissect up the whole thickness of the pectineus muscle, contenting myself with the pectineus fascia and a portion of the underlying muscle, the amount depending on the thickness and strength of the fascial covering. I was led to adopt this method for the same reasons which influenced Mr. Watson

Cheyne, and I have now operated on four patients. Three of them did perfectly well and did not require a truss or pad after the operation. My fourth case (October, 1892) was one of strangulation of five days' duration. The gut was very congested, but not gangrenous. I took only a thin layer of muscle, and perhaps fortunately so, since the wound, which had healed by first intention under one dressing, broke down again about the tenth day and a small fecal fistula was formed. The operation is sound in principle, presents no difficulties in performance and gives an excellent result.

I am, Sirs, yours faithfully,  
Harley-street, Nov. 10th, 1892. C. STONHAM, F.R.C.S. Eng.

### FOREIGN BODIES IN THE BLADDER AND INDIAN SUPERSTITIONS.

To the Editors of THE LANCET.

SIRS,—Surgeon-Major D. Davidson, civil surgeon of Satara, a short time ago, in communicating an unusual case of vesical calculus to THE LANCET, stated that the nucleus was formed of a small doubled-up twig, and added that he could not clearly ascertain how or why the foreign body had been introduced into the bladder. A few days ago I had a man under my care whose case may throw some light upon the subject. I removed a stone, weighing upwards of two ounces, from the bladder of the patient, a Jogi, in which the concretion had formed round a small piece of "amar-bel" (a species of viscum), a parasitic plant, with fine, smooth stems, which infests certain trees, and is, as its name, "the deathless creeper," would perhaps seem to indicate, regarded as being possessed of special virtues. The Jogi, or Yogi, is one who attempts to attain union with the Supreme Being by means of abstract contemplation. My patient explained that he was accustomed to cleanse his urethra with a piece of the "amar-bel" stem in order that he might fit it for the last passage of his soul out of the body in a state of purity, so as to avoid the necessity of another—or at least of a lower—birth, and that two years ago it had slipped back into the bladder. It is thought by Hindu Yog philosophers that the soul leaves the body by one or more of ten outlets (*dash-dvár*), of which the eyes, ears, and fontanelles are pure, and the nostrils, mouth, anus, and urethra are impure. Sometimes, if there be a discharge from any of the impure passages at the time of death, the soul may take its exit by them and thus become defiled and takes a lower birth, hence the Jogi tries during life to minimise the evil by cleansing every road as much as possible. The modes of effecting this are described in various works, and some are remarkably curious. I am informed by a very enlightened Rajput noble that warriors do not take opium before going into action in order to acquire a little spurious courage, as some have supposed, but to induce constipation, so that, if fatally wounded, the sphincters may not be relaxed, and thus the soul may pass away by an upper exit. It is true that Krishna said to Arjuna in the Bhagavat Gita that one who was killed in battle would go to heaven, but it is as well to make sure of a safe journey for the soul a Hindu thinks. In judicial death by hanging there is of course the prospect of the soul having to leave the body by an objectionable channel, but in addition there is the certainty that the prisoner does not die on the earth and so his spirit becomes a pisach, a chut or demon. This explains what always seems to the spectator the unfeeling action of the friends of a Hindu when he is on his deathbed at which time they always place him on the ground in order that he may expire there.

I am, Sirs, yours faithfully,  
T. H. HENDLEY, Surg.-Lt.-Col., C.I.E.,  
Jeyapore, India, Oct. 25th, 1892. Residency Surgeon.

### "THE ETHICS OF OPIUM AND ALCOHOL."

To the Editors of THE LANCET.

SIRS,—Let me give, without comment and very briefly, with reference to the discussion on the opium habit generally and of Dr. Mouat's extenuation of the practice in particular, at p. 1090 of THE LANCET of Nov. 12th, some experience of mine and of other medical officers during the China campaign of 1860 of the force engaged in which Probyn's and Fane's irregular cavalry formed a part. These splendid native horsemen were habitual indulgers in that narcotic, and as no provision had been made by the commissariat in

China for its issue as an ordinary ration the men were rendered quite incapable of military or any other duty, even of cleaning their horses, by its suppression. No opium being at hand, commissariat "indents" were made to the Medical Department for a provisional supply in quantities that were so excessive as very soon went far to exhaust the store. As soon as the opium ration was served out the temporary disability immediately disappeared. It is to be presumed that the consumption of the drug by these native troopers was comparatively moderate. They certainly were what Dr. Mouat terms as a class exceptionally bright and intelligent, "with broad frames, brawny muscled, pliant skins," and in every way unusually active and efficient soldiers. Yet their collapse on the cessation of the stimulant seems clearly to prove that, under the most favourable circumstances, the opium habit is injurious in a high degree to the nervous system and ought to be discouraged, in spite of fiscal and all other considerations, by any truly scientific code of preventive State medicine.

I am, Sirs, yours obediently,  
R. LEWINS, M.D. Heidelb.,  
Surgeon-Lieutenant-Colonel (Retired).

Nov. 14th, 1892.

## DIPHThERIA AND SEWER GAS.

To the Editors of THE LANCET.

SIRS,—Your reviewer of the recent "Treatise on Hygiene and Public Health" calls attention to a point of great importance, especially at the present time, when diphtheria is more prevalent in London than ever before. Is there a causal relation between sewer gas and diphtheria? As your reviewer says, some noted authorities say no. On the other hand, many say yes, besides Professor Notter; among them Drs. Thorne Thorne, Thursfield, Sykes, and Mr. M. Adams (see "Epidemics, Plagues, and Fevers"). I have been recently led to suspect manhole ventilators as a cause of diphtheria in this parish; and it has occurred to me whether the increase of diphtheria in London in recent years may not be partly accounted for by the increased ventilation of sewers—i.e., ventilation which allows the escape of sewer gas in improper places, without being sufficient to render it innocuous. It would be interesting if any who have studied this question would give their experience, and I should be much obliged for reference to any literature on the subject.

I am, Sirs, yours truly,  
SIDNEY DAVIES, M.D. Oxon., D.P.H. Camb.,  
Nov. 16th, 1892. M.O.H., Plumstead.

## "ARREST OF HÆMORRHAGE AFTER TOOTH EXTRACTION BY HOT WATER."

To the Editors of THE LANCET.

SIRS,—Your annotation on the above subject leads me to think that the following illustrative case may be of interest to your readers. In April, 1891, while acting as "locum tenens" at Freshford, I extracted a tooth from a young woman. There was some bleeding at the time, but it had ceased before she went away. It soon recurred, however, and during the next three days she lost, at intervals, a large quantity of blood. The cavity was plugged several times by Dr. Flemming and by myself. Each time we succeeded in stopping the hæmorrhage, but it always recurred whenever the patient removed the plug, so that we were frequently being sent for. Finally, I decided to try syringing with hot water. I used water as hot as I could bear to put my hand into. Immediately on the first impact of the hot water the bleeding ceased. I desisted at once, but the oozing soon recommenced. I then syringed continuously for some four or five minutes. The hæmorrhage ceased, the gum became pale and eventually completely blanched. There was never any recurrence after this. The patient complained of no pain, no sloughing followed, nor were there unpleasant after-results of any kind.—I am, Sirs, yours faithfully,

H. WILLOUGHBY GARDNER, M.D. Lond.  
Shrewsbury, Nov. 15th, 1892.

## "ELECTROPATHIC ADVERTISING."

To the Editors of THE LANCET.

SIRS,—I beg to inform you that I have commenced an action for libel against the newspapers to whose article you refer in your annotation on "Electro-pathic Advertising" in

your issue of Sept. 24th, and I shall also hold you responsible. I request you to insert this letter in your next issue.

I am, Sirs, your obedient servant,

HERBERT TIBBITS, M.D., F.R.C.P. Edin., &c.  
Welbeck-street, W., Nov. 14th, 1892.

## CHOLERA AND THE GERM THEORY: A CRUCIAL TEST.

To the Editors of THE LANCET.

SIRS,—We have been recently informed that the Imperial Cholera Commission in Germany (a country which supplies us with such numerous therapeutic surprises) states that "wine—claret or hock—was found to kill the bacilli [of cholera] in a few minutes." Hitherto, when it was pointed out that in no single instance had the germ theory borne fruit in the treatment of disease, the excuse was pleaded that such agencies as destroyed the bacilli had an inimical effect on the system, and could not therefore be administered as remedies. Now here, according to this Imperial Commission, we have a totally different case. If cholera be due, as in Scotland we have been recently assured by Dr. Grainger Stewart, and as we are constantly being assured through all the medical journals at home and abroad, to the comma bacillus, and if claret or hock kills the comma bacillus in a few minutes, then claret and hock ought surely to cure cholera; here there can be no excuse that these beverages act as poisons to the system. Tea also, according to the same authority, killed the bacilli in one hour. If the Imperial Commission be right, and if the bacillary theory of disease be well founded, I submit that the cure of cholera should now be *un fait accompli*. If it be nonsense, as I believe it to be, then here we have another instance of the inanity of the whole thing. If, again, cholera be due to the presence of the comma bacillus in the bowels, why use tannin injections as recommended by Alexinsky of Jarsolaol (whoever he may be) and Professor Cantani of Naples, or why use astringents by the mouth? Would not purgatives to expel the bacillus be indicated? What with Dr. Brown-Séguard's "organic injection," injections of the juice of the thyroid gland, and of the serum of dogs and horses, truly the "science" of therapeutics may be said to be in a bad way.—I am, Sirs, your faithfully,

Glasgow, Nov. 11th, 1892. D. CAMPBELL BLACK, M.D. Glas.

## "AN ACCIDENT UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of the 1st inst. I find a note on "An Accident under Chloroform" by Surgeon-Lieutenant-Colonel Lawrie. I think this is the first accident of the kind ever recorded as having taken place in Surgeon-Lieutenant-Colonel Lawrie's practice of some scores of thousands of cases of chloroform administration. It is strange that it should have occurred after so much experiment, and so much assertion that if chloroform were only always administered everywhere according to the Hyderabad method its use would always be absolutely safe. If, however, such an accident can occur when the drug is administered under Surgeon-Lieutenant-Colonel Lawrie's personal supervision, and by one of his own students, it is clear either that the supposed safety of the drug has been exaggerated or that there are other reasons for its undoubted safety as administered in India compared with the conditions which obtain in England and in temperate and cold countries generally. Here in Madras, we have never had a death from chloroform, but we have had occasionally an "accident" similar to that described by Surgeon-Lieutenant-Colonel Lawrie, and in which a fatal issue has been averted by artificial respiration. My experience, as also that of Surgeon-Lieutenant-Colonel Lawrie, is very limited in regard to the administration of anaesthetics at home; and so I speak under correction when I say that if there is anything more puzzling than the safety of chloroform in India as compared with England, it is the extreme readiness with which apparently asphyxiated patients respond to artificial respiration here as compared with England.

I am convinced that our pure freely circulating air (for all operations are practically done in the open air); the dilute form in which the chloroform is necessarily administered owing to the high temperature of the atmosphere; the constitutional peculiarities of our patients, the result of dif-

ference in food, clothing, and temperate habits—I say I am convinced that these different conditions have a great deal more to do in rendering chloroform anaesthesia safe here than any particular difference in the methods we adopt. In regard to the matter of temperance alone, every surgeon in India knows how differently intemperate patients act under chloroform from the usual temperate individuals he has to deal with. We readily notice the difference here because the intemperate are as yet few and far between. Again, our patients never “funk” chloroform as Europeans constantly do. Surgeon-Lieutenant-Colonel Lawrie, in a late paper of his, has stated that till Hyderabad methods were introduced the patients used to bolt the moment they saw the chloroform bottle. English readers must take this statement as referring to Hyderabad alone. I venture to say there is not another surgeon in India who has had a like experience. Our patients as a rule simply cry out for chloroform for the most trifling operations. I have been watching this closely for the past ten years, and it has always been the same. So the fact is they do not fear it; the air is pure and warm; they are temperate, rarely muscular to the European degree, rarely bilious from over-feeding with loaded bowels, and always practically naked—everything in fact as favourable as can be for the ready reception and equally ready elimination of a volatile drug like chloroform. Surgeon-Lieutenant-Colonel Lawrie seems to approve of holding down a struggling patient. I think this approval is ill-advised. If the patient struggles and his movements are forcibly and completely restrained he closes his glottis that he may the better resist opposition, and elimination of the chloroform in his blood is thereby effectually arrested. Our custom here is to allow a patient's arms to swing about freely and to restrain only partially all other movements. He is simply prevented from removing the chloroform cap from his face, an attempt he is sure to make when becoming unconscious. I have come to regard this point as of some importance.

I am, Sirs, faithfully yours,

Oct. 22nd, 1892.

SOUTH INDIA.

### “FELIXSTOWE SPA.”

To the Editors of THE LANCET.

SIRS,—In the current issue of THE LANCET Dr. Jones gives a glowing account of the charms, and especially of the sanitary perfection, of Felixstowe. Oddly enough, however, he does not mention its system of sewerage. Is this because he hesitates to speak evil of the absent?

I am, Sirs, yours faithfully,

Nov. 14th, 1892.

GOLFER.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *Sad Boating Fatality on the Tyne; a Medical Student Drowned.*

ON Saturday evening last a sad boating fatality took place on the Tyne, whereby a student at the Medical College and a resident dresser at the infirmary lost his life. The facts are shortly as follow: Mr. Benjamin May and companions hired a four-oared outrigger to have a little exercise on the river, and all went well until about six o'clock, when the evening getting very dark the boat collided with a Blaydon steamer and all the rowers were upset into the river. They contrived to swim to the bank with the exception of Mr. May, who was missed, and although his companions made desperate efforts to reach him his body was not found until the following day, when it was recovered and taken to the infirmary, where it lies until interment to-day. Mr. May, who was in his twenty-first year and had nearly completed his curriculum, was distinguished as a student and carried off many prizes during his course. His remains were followed by professors, lecturers, and infirmary officials, and by nearly everyone of his sorrowful fellow-students, by whom he was held in the highest esteem.

### *Proposed Temporary Hospital for Cholera on Newcastle Town Moor.*

The sanitary and other committees concerned in the erection of a cholera hospital on the Town Moor have under their consideration a proposal to lay down concrete foundations and to put in the necessary sewers so that in case of a visitation of cholera emergency temporary hospitals could be promptly erected on the enclosed sites of about one and a half acres.

### *Dr. Maclaren of Carlisle on Alpine Climbing.*

Dr. Maclaren of Carlisle, who has been in the habit of visiting Switzerland for some years past and has therefore some experience of the pleasures and dangers associated with Alpine climbing, gave an attractive and most interesting lecture on the subject last week in the Viaduct Hall, Carlisle. He thought if all people who were still young would pay two or three visits to Switzerland they would be well repaid in health, and the general interest in nature which would be aroused. Young men, he said, used to cricket and football might commence to climb at once. Three or four could join together with one guide (a guide, though not always necessary, was advisable, and well repaid expense).

### *Tobacco and Snuff for Workhouse Inmates.*

The Lanchester board of guardians, in reference to the circular of the Local Government Board authorising an allowance of tobacco and snuff to non-able-bodied paupers, have represented to the Local Government Board that it might withdraw the term “non-able-bodied paupers,” and leave it to the discretion of the master to recommend these luxuries under certain circumstances to working inmates. Old men and women smokers were to be allowed two ounces per week.

### *Miscellaneous Items.*

The Gateshead guardians have resolved in consequence of the congested state of the County Lunatic Asylum to appoint a committee to consider the necessity and advantage of establishing an asylum on the guardians' land for the reception of the lunatics of the union. From this and other indications apparent in the same direction it appears to me that the day for huge lunatic asylums is over; at all events, that they have now reached their limit in the north.—Last week an interesting presentation took place at the Central Hall, Spennymoor, of a purse of gold and a medal suitably engraved with an illuminated address to Police-constable R. Boal, who discovered the fire at the North-Eastern Hotel and gallantly saved the lives of the inmates.—A Local Government inquiry has been held at Eston, near Middlesbrough, to sanction the purchase of land for a sanatorium for the district, to which there was no opposition.—Mr. Veitch of Middlesbrough has presented to the museum of that town a stone axe head which had been dredged in the River Tees. It is said to be a very fine relic of the stone age.—One of the events of the week has been the reopening of the Newcastle Art Gallery with a brilliant conversation, which was attended by the mayor and corporation and our principal citizens. The Newcastle Art Gallery is something unique, for under the same roof it includes the magnificent picture galleries, a concert hall and various club-rooms, besides separate rooms large enough for the meetings of our various scientific societies. There has been a great need for this in Newcastle, as we have nothing in the way of a medical institute.—In my last notes I mentioned that the seal had been driven from its haunts on the Northumbrian coast by the steamboat traffic. I have been sorry to hear, however, that on Saturday last a boat proceeded to the Seal Rock (one of the Farne Islands) in search of a female seal and her cub which were seen on the rock. They escaped. Not so a fine bull seal, which the fishermen shot. It is said to weigh forty-five stone, and the skin measures eight feet by five feet.

Newcastle-on-Tyne, Nov. 16th.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *Royal College of Surgeons.*

AN election for a Member of Council in the room of Mr. J. Kellock Barton, resigned, was held on Monday, when Dr. F. T. Heuston, Professor of Anatomy in the Medical Schools of the College, was elected by a large majority.

### *Graduates' Memorial Building: Trinity College.*

A sum of £6500 has already been received for the Graduates' Memorial of the Tercentenary of the University of Dublin, and it is confidently expected that before the year terminates an additional £500 will be added to the amount. The governing authorities of the University have consented to give a suitable site for the proposed building, and the matter will soon engage their consideration.

### *Dublin Hospital Sunday.*

The nineteenth annual collection in aid of the Dublin

hospitals took place last Sunday, and, so far as can be ascertained, it is believed that the returns will prove satisfactory. The hospitals aided by the fund receive annually upwards of 11,000 patients, attend 4500 lying-in women at their own homes, treat as extern patients more than 15,000 accidents, and relieve many thousands at their dispensaries. They contain about 1200 beds, many of which, however, cannot be utilised for want of funds. The work done by these hospitals costs some £43,000 yearly, of which about 10 per cent. is supplied by the Hospital Sunday Fund.

#### *Richmond Lunatic Asylum.*

Last year there were about 300 inmates of this establishment over the estimated accommodation, and the hygienic condition, the inspectors of asylums assert, remains unsatisfactory, as shown by the frequent occurrence of dysentery and other forms of zymotic disease. The governors have at last decided to obtain an estate in the neighbourhood of Dublin, and there erect a second asylum for the district. There is little doubt that, before long, it will be found more convenient for the counties of Dublin, Louth, and Wicklow to separate from the city of Dublin, as the patients belonging to the metropolis are increasing with such rapidity as to render it likely that a separate institution will be found essential for their treatment, but in the meantime the scheme adopted by the governors has the advantage of presenting the fewest difficulties. Not alone is the Richmond Lunatic Asylum overcrowded, but the workhouses situated in Dublin contain a large number of persons of unsound mind for whose care and accommodation more suitable surroundings are required. Considering the number of the insane in this district who require asylum care, a second institution affording equal accommodation to the existing Richmond Asylum will be required.

#### *Cork South Infirmary: Lady Students.*

At the monthly meeting of the trustees of the South Infirmary, Cork, held on the 11th inst., a motion by Colonel Donegan to rescind a resolution passed by the trustees at a previous meeting, permitting lady students to attend clinical instruction in the hospital. After considerable discussion the motion was lost by 14 votes to 5.

#### *Cork Hospital Saturday.*

Cork has done better than in 1891 by about £100. The street collections and private donations amounted to nearly £800, which is encouraging.

#### *National Registration of Plumbers.*

The general meeting of the members of this association was held recently. Professor Anthony Roche, in seconding one of the motions, said that he considered their Association one of the greatest possible importance from a sanitary point of view. Dr. McWeeney and Sir Charles Cameron also spoke. The latter said the association was not a trades-union, but was for the purpose of protecting the public on the score of health, for the public ought to be protected against incompetent persons calling themselves plumbers who were not able to discharge the duties which they undertook. The law said that no one could officiate as a medical man unless his name was on the Medical Register, and he could not be put on the Register unless he could produce evidence as to his competency. This was all they required with this Registration Association.

#### *Royal Hospital for Incurables.*

At a meeting of the governors held last Monday, Mr. Wm. Russell, L.R.C.S.I., was elected Resident Medical Officer. Mr. Russell was recently resident medical officer of Monkstown Hospital.

The following have been placed on the Commission of the Peace:—Wm. Kerr, M.D., for Armagh; Richard Harold, M.R.C.S. &c., Castleisland, for Kerry; and James Kilbride, L.R.C.P.I., M.R.C.S. &c., Athy, for Kildare.

Nov. 15th, 1892.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *Electricity and Diagnosis in Gynecology.*

At a recent meeting of the Société Française d'Electrothérapie M. Apostoli, whose name is so largely associated with the use of electricity in gynecological practice, read a paper on some New Points in the Uses of Electricity in Diagnosis in Gynecology. Electricity, he held, was not only

of undoubted benefit in uterine therapeutics, but it was also a great aid in gynecological diagnosis.

#### *Alcoholism in Switzerland.*

According to the official returns for the year 1891, out of a total of 6885 deaths of persons over twenty years of age in the fifteen most populous towns of Switzerland, 425 were due to alcoholism—in other terms, 6 per cent. Of these 425 deaths owing to this sad cause 366 were men and 59 women. Of 366 individuals who succumbed to this vice 188 belonged to the working-class category and 178 to the superior, or educated, classes, which proves—when the relative proportion of these two classes in the social scale is taken into consideration—that alcoholism is more frequent in cultivated society. It is worthy of note that the fifteen centres which are included in this statistical computation form only the sixth part of the total population: so that if the figures 425 be multiplied by 6 it is found that the number of deaths due to alcoholic vice in 1891 in the Helvetic Confederation amounts to the respectable, or rather disreputable, figure of 2550. Let those who will, then, take comfort in the poor consolation that the United Kingdom is not the only part of the world afflicted with what has been not inapily termed the "English disease."

#### *Hygiene in Schools.*

The science of hygiene bids fair to become popularised in France. The strides that this branch of preventive medicine has made in this country within the last few years are indeed considerable when the conditions existing under what may be termed the not very distant pre-hygienic epoch are considered. M. Strauss, a municipal councillor, proposes to create a municipal chair of School Hygiene destined to give instruction in this subject to the teachers in the municipal schools. The future municipal professor of hygiene will be elected, after a public competition, from the medical inspectors of schools of the city of Paris.

Paris, Nov. 16th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

#### *Dr. S. Guttman on the Recent Cholera Epidemic.*

At a meeting of the Society for Internal Medicine, on the 7th inst., Dr. S. Guttman spoke on the course taken by the last cholera epidemic. He said that the pestilence had taken its usual course from its home at the mouths of the Ganges and the Brahmapootra westwards to Russia. As usual, before spreading to Europe, it had raged with more than wonted fury in the basin of the Ganges. How it had got to Paris, however, had not yet been cleared up, but one must remember that the journey from Bombay to Paris took only about eighteen days. In Paris the outbreak of cholera had long been kept secret. In spite of the unambiguous results of microscopic examination, Professor Peter had maintained only the other day that the Paris epidemic was not Asiatic cholera. On the pretence that it was cholera nostras, all precautions had been neglected at first in Paris. The suburbs on the Seine below Paris had suffered most, the river there containing all the filth that the big city poured into it. A correspondence which he (Dr. Guttman) had had with the sanitary authorities of Antwerp proved that the cholera cases which occurred in that city were directly traceable to Paris and its environs. This being so, he thought it quite certain that Hamburg got the contagion from Antwerp, Paris, or Marseilles. The Hamburg epidemic had taught with terrible emphasis what an important part drinking-water may play in spreading cholera. The importance of other hygienic conditions had also been shown by the circumstance that, in direct contrast with what had happened in France, severe as the Hamburg epidemic had been, new cholera foci had nowhere been formed in Germany, a fact which had also struck French medical men. Dr. Guttman threw some light on the history of the dispute between the localists and contagionists, and concluded by describing how the knowledge of cholera had been deepened and extended by Koch's discovery of the germ of the disease.

#### *Treatment of Fractures of the Leg.*

At a meeting of the Society of the Charité Doctors on the 10th instant, Dr. Korsch of the 12th Grenadiers, assistant in Professor Bardeleben's ward in the Charité, delivered a lecture on the treatment of fractures of the legs by so-called ambulatory bandages. The method is not new. It was invented by a trussmaker at Göppingen named

Hessing, who furnishes patients in whom a false joint has formed at the place of fracture with an apparatus which enables them to walk about without inconvenience. The making of this apparatus, however, demands a several weeks' stay at Göggingen, and it is so dear that only rich people can buy it. Dr. Korsch has now proved that one can enable patients with fractures of the tibia or fibula, or of the ankle, to walk about by the much simpler means of a plaster-of-paris bandage. He has extended the application of the method to cases in which not only the bones, but also the soft parts covering them, are injured, and to fractures of the femur. In the latter cases he supplements the bandage by a splint, which can be improvised by any locksmith out of telegraph-wire and hoop-iron, or, if the latter cannot be got, sheet-metal.

#### Miscellaneous News.

Professor Hirsch of Berlin has finished his "History of the Medical Sciences," at which he has been working for years.

The work of the Imperial Office of Health has grown to such dimensions that its present premises have become too small for it, and a new building is to be erected.

Herr Schloski, director of the street-cleaning department in Berlin, and Dr. Weil, who were sent by the magistrates of this city to London to study the burning of house-refuse there, have now reported, and the magistrates have resolved to instruct the building department to draw up a plan of a destructor and an estimate of its cost.

The death-rate of Hamburg and its environs for the week which ended on Oct. 29th was only 17.7.

The friends of Hermann von Helmholtz have collected and published the speeches which were delivered at the celebration of his seventieth birthday.

Berlin, Nov. 15th.

## Obituary.

EDWARD COCK, J.P., F.R.C.S.

(CONSULTING SURGEON TO GUY'S HOSPITAL).

ON Aug. 1st, at the great age of eighty-seven, this eminent and popular surgeon died at Kingston-on-Thames, where he had resided for thirty-two years. He had given up hospital work for twenty-one years, but he might have been seen up to the last six or seven years coming up to his house in Dean-street, St. Thomas-street, S.E., daily for private consultations. His professional opinion was much valued by a large circle of friends, and his personal qualifications endeared him to all who came under their influence. "Teddy Cock's" last tale was always popular with Guy's men, and his cheery voice had a friendly ring in it which was acceptable. Edward Cock was born at Tottenham, where his parents resided. His family was related to the Clines. Sir Astley Cooper, who married Mr. Cock's aunt (his father's sister), in the early part of his career was a frequent visitor and inmate of his grandfather's and father's house (frequent mention of this will be found in the Life of Sir Astley Cooper, by Mr. Bransby Cooper). At the age of sixteen Mr. Cock was bound apprentice to Sir Astley Cooper and commenced his anatomical studies at St. Thomas's Hospital, where, as the two Borough hospitals were then united, the surgical and anatomical department of the school was carried on. The warmest feelings of mutual esteem and friendship always existed between the illustrious master and his pupil, and only ceased with the death of the former in 1841. A few years witnessed the separation of the two hospitals and the establishment of a new and distinct school at Guy's. There events naturally drew Mr. Cock to the place which was to be considered his home and *alma mater*, and where his illustrious uncle still continued to fill the post of surgeon. Mr. Cock took an active part in the arrangements for the new school and worked hard at the formation of an anatomical museum. When the school opened in 1826, although still an apprentice, he undertook the duties of Demonstrator of Anatomy. From that time, during the succeeding twenty years, he continued to teach anatomy in connexion with Mr. Bransby Cooper, and subsequently with Mr. Hilton, and only resigned his appointment into younger hands when the duties of hospital surgeon and his increasing private practice, added to the wear and tear of lecturing, began to undermine his health. On his relinquishment of the anatomical chair the former pupils of the hospital who had studied anatomy under his tuition availed themselves of the opportunity to present him with a handsome piece of plate. Mr.

Cock became a member of the College of Surgeons in the year 1828, and an Honorary Fellow amongst the first batch created in 1843. He was elected a member of the Council of the College in 1856, a member of the Court of Examiners in 1867, and President of the College in 1869. In 1838, he was appointed assistant surgeon to Guy's Hospital; but for some years previously the engagements of Mr. Aston Key and the absence of Mr. Morgan, who lived out of town, had thrown upon him the active duties of hospital practice and afforded him frequent opportunity of performing many of the operations of surgery.

In the year 1847, on the decease of Mr. Morgan, he became full surgeon; the subsequent death of Mr. Aston Key in 1849 placed him in the position of second surgeon; the death of Mr. Bransby Cooper a year or two later made him senior surgeon, and for twenty-two years he served the hospital in this capacity. He then retired from active work at the hospital and became its consulting surgeon—a position he retained till his death. Mr. Cock held the office of President of the Hunterian Society, was perpetual honorary president of the Pupils' Medical Society at Guy's, and always felt and evinced a zealous attachment and devotedness to the institution where he was educated. He was rigidly exact in his attendance to his hospital practice, and seldom if ever suffered private engagements or other interests to interfere with his public duties. He was a clear and fluent lecturer and his clinical lectures were always well attended.

As an operating surgeon Mr. Cock's experience was very extensive and, upon the whole, successful. In operations for harelip and in other cases where it is necessary with accuracy and precision to bring together and adjust two cut edges or surfaces he had a method of his own; this he accomplished by the uninterrupted suture, sewing the two edges together along their entire length with a fine needle and ligature. Mr. Cock, in his early days, was the author of several reviews, chiefly of French and German works in the British and foreign and other journals. While Demonstrator of Anatomy he published a work entitled "Dissection of the Vessels, Nerves of the Head, Neck and Chest," in which the different parts were described as they were successively brought into view under the scalpel of the dissector. The work was somewhat imperfect as only embracing a portion of the human frame, but Mr. Cock's "Head and Neck" was a model of clearness and precision and was deservedly popular. In the Royal Medical and Chirurgical Transactions several years back will be found his account of congenital malformations of the internal ear from dissections of patients who died in the Asylum for the Deaf and Dumb. From time to time he gave to the medical world short memoirs on different subjects whenever he considered that his experience entitled him to do so. These will be found dispersed in the Guy's Hospital Reports and the *Medical Gazette*. Amongst these are a series of cases of laryngotomy and tracheotomy, with remarks on the operation, and on the use of the trocar and cannula in its performance. Mr. Cock was one of the first, if not the first, to perform the operation of œsophagotomy. The Medical and Chirurgical Transactions for 1851 contains a curious and unique case of varix of the posterior tibial vein, the apparent result of a wound of the popliteal artery and vein eleven years previously, for which the femoral artery had been tied. The limb was amputated by Mr. Cock under circumstances described in the paper. During the session of the Royal Medical and Chirurgical Society for 1851-52 a paper by Mr. Cock was read and was published in the volume for 1852. It was entitled "Remarks on the surgical operations usually adopted in cases of retention of urine, together with an abstract of cases in which the bladder was punctured through the rectum, either for relieving distension or facilitating the cure of impermeable stricture." Forty cases of stricture of the bladder were enumerated, in the majority of which the operation was performed by Mr. Cock. The remainder occurred in the practice of his colleagues and came under his immediate observation. Considerably more than half of these cases occurred previously to the year 1850, and their precise dates are accurately stated in the published memoir. Mr. Cock did not, as has been stated, recommend puncturing the bladder in all cases of difficult stricture, but thought that in some few instances it might be found a better alternative for the patient than a tedious course of damaging catheterism.

The above, although but a brief outline of the career of a surgeon who formed a connecting link with the Clines, the Coopers and the Keys and the united schools in the Borough will doubtless prove of interest to our readers.

## Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed the First Professional Examination for the diploma of Fellow at a meeting of the Board of Examiners on the 14th inst. :—

*Anatomy and Physiology.*—Thomas Wilson, M.R.C.S., of University College and Mason's College, Birmingham; Edward Tenison Collins, M.R.C.S., Cambridge and Edinburgh Universities and Mason's College, Birmingham; John H. Crawford, of Edinburgh University Extra-Mural School; Percy R. Cooper, of Owens College and Royal Infirmary, Manchester; John W. Haines and Evelyn G. B. Adams, of St. Bartholomew's Hospital. (Ten candidates were referred back to their professional studies for six months.)

Passed on the 15th inst. :—

Herbert E. Counsell, M.R.C.S., and Charles Pollard, M.R.C.S., of Guy's Hospital; Charles E. Baker, M.R.C.S., of Cambridge and St. Bartholomew's Hospital; George O. Rigby, of Melbourne University and University College, Liverpool; Cuthbert H. J. Lockyer, of Charing-cross Hospital; Francis C. Bottomley, of Cambridge University and St. George's Hospital. (Nine candidates were referred back to their professional studies for six months.)

Passed on the 16th inst. :—

Douglas Crawford, of Berlin and Edinburgh Universities and University College; and Robert W. Michell, of Cambridge University and St. Bartholomew's Hospital. (Ten candidates were referred back to their professional studies for six months.) Of the forty-three candidates who presented themselves for this examination fourteen passed and twenty-nine were referred.

The following are the arrangements for the Final Examination for the diploma of Fellow, for which thirty-four candidates have entered their names :—Monday, 21st inst., 1.30 to 5.30 P.M., Written Examination; Tuesday, 22nd, 2.15 to about 5.30, Clinical Examination, *visà voce* and Written; Wednesday, 23rd, 1.30 to about 5, Operations; Thursday, 24th, 2 to 3.45, Surgical Anatomy; Friday, 25th, 5 to 8.30, Pathology. The examinations on Monday, Tuesday, Wednesday and Thursday will be held at the Examination Hall, Victoria Embankment. On Friday the Examination will be held at the Royal College of Surgeons. Candidates will be required to attend on each of the above dates.

**FOOTBALL CASUALTIES.**—The following casualties occurred on Saturday, the 12th inst. In a match at Felixstowe, between teams representing Landguard Fort, Felixstowe, and the Orwell Works, Ipswich, one of the latter team, aged twenty-four, sustained injuries to the abdomen, from which he died, in the Ipswich Hospital, on the following night. During a match between Warrington and Mossley a Warrington half-back fractured his clavicle. In the course of a match at Keighley, between Keighley and Haworth, a three-quarter-back of the former team broke two of his ribs. Whilst playing a match at Cowdenbeath, between teams representing the Cowdenbeath and Dunfermline clubs, one of the Cowdenbeath half-backs fractured his right leg.

**THE JONSON MEMORIAL FUND.**—At a meeting of the committee of the Jonson Memorial Fund, held at Sir James Paget's house on Nov. 3rd, the bust of the late Mr. G. C. Jonson was exhibited, and was much admired, the likeness being thought an especially good one. It was unanimously resolved : "That the bust of the late Dr. G. C. Jonson be sent to the next exhibition of the Royal Academy, in accordance with the wish of Mr. T. Brock, R.A., the sculptor, and afterwards be placed in the school-room of Epsom College." By the kind permission of Mr. Brock the bust will be on view to subscribers any day—Saturday and Sunday excepted—at his studio, 30, Osnaburgh-street, Regent's-park, before being sent to the Royal Academy.

**LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.**—A meeting was held at Park House, Croydon, on the 14th ult. (Dr. Duncan in the chair), to establish a branch of the above Society for Croydon and the neighbouring places. Dr. Mead, of Newmarket and London, explained the constitution and objects of the Society, and answered several questions on points of detail. The meeting unanimously resolved to form a division for Croydon and the surrounding places. Dr. Duncan was elected president; and Drs. Philpot, Richardson, Rosser, Parsons-Smith and Thompson, vice-presidents. A council was formed consisting of Drs. Beard, Cooper, Drew, Ormerod, Vincent, Wayte and Webster, and Dr. Whishaw was elected honorary secretary.

**ANDERSON'S COLLEGE MEDICO - CHIRURGICAL SOCIETY, GLASGOW.**—The second meeting of this Society was held on Saturday, the 12th inst., in the college buildings, when Professor A. M. Buchanan, M.A., M.D., delivered his inaugural address as honorary president. The subject was, "Medical Science, its Uncertainties, and how to Overcome Them." There was a large audience, who listened to his scientific oration with great interest. In treating of his subject he urged the importance of close attention to facts and their proper association and correct generalisation, at the close of the address receiving quite an ovation from those present. The meeting terminated with a vote of thanks and cheers for the honorary president.

**METROPOLITAN ASYLUMS BOARD.**—The number of patients in the several fever hospitals of the Metropolitan Asylums Board at midnight on Nov. 15th was as follows :—Eastern Hospital, 391 scarlet fever, 95 diphtheria and 47 enteric fever; North-Eastern Hospital, 458 scarlet fever; North-Western Hospital, 397 scarlet fever, 79 diphtheria and 21 enteric fever; Western Hospital, 301 scarlet fever, 36 diphtheria, 1 typhus fever and 14 enteric fever; South-Western Hospital, 305 scarlet fever, 54 diphtheria and 23 enteric fever; South-Eastern Hospital, 388 scarlet fever, 14 diphtheria and 16 enteric fever; Northern Hospital, 929 scarlet fever and 14 diphtheria; Gore Farm Hospital, 812 scarlet fever. At the South-Eastern Hospital there were 3 cases and in the hospital ship *Atlas* 8 cases of small-pox.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

- BAILEY, S. H., M.D., M.B., C.M., L.S.A., has been appointed Medical Officer to No. 5 District of Nottingham Union, vice E. C. Buckoll, resigned.
- BARTON, WM. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Wyeside Sanitary District of the Weobley Union.
- BURTON, R. G., M.D., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Rural Sanitary District of the Brentford Union.
- CHAPMAN, CHARLES W., M.R.C.P., has been appointed a Physician to the National Hospital for Diseases of the Heart and Paralysis.
- COOKE, WILLIAM H., M.R.C.S., L.R.C.P., L.S.A., has been appointed Senior House Physician to St. George's Hospital.
- DALBY, A. W., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Froce Rural and Urban Sanitary Districts.
- DARRELL, H. W., M.D. Toronto, C.M., L.R.C.P. Lond., has been appointed Medical Officer for the Third Sanitary District of the Blofield Union.
- DUMMERE, H. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Fourth Sanitary District of the Bromley Union.
- HEATON, GEO., M.B., B.Ch. Oxon., F.R.C.S., has been appointed Visiting Surgeon to the Children's Hospital, Birmingham, vice Hunt, resigned.
- MASON, WM., L.R.C.P., L.M., L.R.C.S. Edin., has been reappointed Medical Officer of Health for the St. Austell Rural and Urban Sanitary District.
- MATHIESON, GEORGE M.B., C.M. Glas., has been appointed Junior Resident Medical Officer to the County Asylum, Stafford.
- MCCACHEN, F. W. D., L.F.P. & S. Glas., L.M., L.S.A., D.P.H. Lond., has been appointed Medical Officer for the Rugby District of the Rugby Union, Medical Officer to the Union House, and Public Vaccinator to the Town of Rugby, vice Angove, resigned.
- MACDONNELL, LUCIUS G. A., B.A., M.B., B.Ch. and B.A.O. Univ. Dub., has been appointed Surgeon to Aramac Hospital, Central Queensland, vice H. J. Hewer, M.B., resigned.
- MCKELVIE, R., M.D., L.R.C.S. Edin., has been appointed Medical Officer for the Workhouse and the Second Sanitary District of the Blofield Union.
- MILLS, JOHN, M.B., B.S. Irel., has been appointed House Surgeon to the National Eye and Ear Infirmary, Molesworth-street, Dublin, vice C. Sullivan.
- MOORE, W. HODGSON, M.R.C.S., has been appointed Honorary Surgeon to the Kidderminster Infirmary and Children's Hospital.
- MORTLOCK, AMBROSE W., M.B., M.S. Edin., has been appointed Medical Officer for the Second Sanitary Division of the Greystoke District of the Penrith Union.
- NEWMAN, D., M.D., C.M., F.F.P.S. Glas., has been appointed Surgeon to the Royal Infirmary, Glasgow, vice Macewen, resigned.
- ROMER, LESLIE R., M.R.C.S., L.R.C.P., L.S.A., has been appointed House Physician to St. George's Hospital.
- STROVER, H. C., L.S.A. Lond., L.A.H. Dub., has been appointed Medical Officer of the Sandy Sanitary District of the Biggleswade Union.
- TAYLOR, DANIEL M., M.A., M.B., M.C. Glas., has been appointed Deputy Coroner for the North Riding of Yorkshire.
- TOWNSLEY, J., M.B., C.M. Edin., has been appointed Medical Officer to the Ardley Local Board.
- YOUNG, CHARLES W. F., M.D. Lond., M.R.C.S., D.P.H. Camb., has been appointed Assistant Medical Officer to the London County Council.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST**, Victoria-park, E.—House Physician for six months. Board and residence, and allowance for washing provided. (Applications to the Secretary, 24, Finsbury-circus, E.C.)
- DEVON AND EXETER HOSPITAL**, Exeter.—Assistant House Surgeon. Salary £40 per annum, with board and lodging, not including alcoholic liquors and aerated waters.
- GENERAL HOSPITAL FOR SICK CHILDREN**, Pendlebury, Manchester.—Junior Resident Medical Officer for one year. Salary £80 per annum, with board and lodging.
- GENERAL HOSPITAL**, Nottingham.—Assistant House Surgeon for six months. Board, lodging and washing provided in the hospital.
- LIVERPOOL NORTHERN HOSPITAL**.—Assistant House Surgeon. Salary £70 per annum, with residence and maintenance in the house.
- NOBLE'S ISLE OF MAN AND GENERAL HOSPITAL AND DISPENSARY**, Douglas, Isle of Man.—Resident House Surgeon; unmarried. Salary £100 per year, with apartments, gas, coal and laundry free.
- NORTH-EASTERN HOSPITAL FOR CHILDREN**, Hackney-road, N.E.—Junior House Surgeon for six months. Salary at the rate of £00 per annum.
- NORTHERN INFIRMARY**, Inverness.—House Surgeon and Dispenser. Salary £70, with board &c.
- PARISH OF BIRMINGHAM WORKHOUSE INFIRMARY**.—Resident Assistant Surgical Officer for the Workhouse Infirmary. Salary £100 per annum, with furnished apartments, rations (which do not include alcoholic liquors), coals, gas, washing and attendance.
- QUEEN CHARLOTTE'S LYING-IN HOSPITAL**, Marylebone-road, N.W.—Resident Medical Officer for four months. Salary at the rate of £00 per annum, with board and residence.
- ST. LUKE'S HOSPITAL**, London, E.C.—Clinical Assistant for six months. Board and lodging provided.
- THE GLASGOW POLICE COMMISSIONERS**.—Physician Superintendent of their hospital, Belvidere. Salary £400 per annum, with house, accommodation, board and attendance. (Applications to the Clerk to the Commissioners, City Chambers, Glasgow.)
- THE NEW LONDON COUNTY ASYLUM**, Claybury, Woodford, Essex.—Medical Superintendent. Salary £1000 per annum, with house, coals, lighting, milk and vegetables. (Applications to Mr. Partridge, London Asylums Committee Office, 21, Whitehall-place, London, S.W.)
- THE LONDON THROAT HOSPITAL**, 204, Great Portland-street, and 72, Bolsover-street, W.—Pathologist.
- VICTORIA HOSPITAL**, Burnley.—Honorary Ophthalmic and Aural Surgeon.
- WESTERN GENERAL DISPENSARY**, Marylebone-road, N.W.—Junior House Surgeon. Salary £50 per annum, with board and apartments.
- WEST LONDON HOSPITAL**, Hammersmith-road, W.—House Physician for six months. Board and lodging provided.
- WEST LONDON HOSPITAL**, Hammersmith-road, W.—House Surgeon for six months. Board and lodging provided.
- WESTMINSTER GENERAL DISPENSARY**, 9, Gerrard-street, Soho.—Resident Medical Officer for one year.
- WOLVERHAMPTON EYE INFIRMARY**.—House Surgeon. Terms £00 per annum, with rooms, board and washing.

## Births, Marriages and Deaths.

### BIRTHS.

- FOULERTON**.—On Nov. 12th, at Brompton-road, S.W., the wife of Alex. G. Foulerton, M.R.C.S., D.P.H. Camb., of a daughter.
- HARRIS**.—On Oct. 30th, at Grosvenor House, Aberystwith, the wife of T. D. Harris, M.R.C.P. Lond., F.R.C.S., of a son.
- HARRIS**.—On Nov. 15th, at Tregorha, Twickenham, the wife of Percy Traer Harris, M.E.C.S., L.D.S. Eng., L.S.A. Lond., of Harley-street, W., of a son.
- HARRISON**.—On Nov. 14th, at Beverley-road, Hull, the wife of Edward Harrison, M.A., M.B. Cantab., F.R.C.S., of a daughter.

### MARRIAGES.

- RICE—HANNAY**.—On Nov. 15th, at All Saints' Church, Leamington Spa, by the Rev. C. H. Rice, B.D. (Rector of Chean and Rural Dean), assisted by the Rev. W. C. Furneaux, M.A. (Vicar of Leamington), and the Rev. A. Nicholson, LL.D., Bernard Rice, M.D. Lond., of 5, Clarence-terrace, Leamington, son of the late Bernard Rice, M.B. Lond., of Stratford-on-Avon, to Lilian Hyde (Zelly), third daughter of W. Hannay, Esq., of Leamington Spa.
- ROBERTS—WEARE**.—On Nov. 15th, at St. Mary's, West Kensington, Dr. Roberts, of Close-gate, Salisbury, to Fanny, widow of Arthur Weare, of Belvidere-villa, Upper Norwood.

### DEATHS.

- BROADWAY**.—On Nov. 3rd, at 61, Kennington-park-road, Sigismund Alexander Wain, Edward Broadway, M.R.C.S. Eng., L.R.C.P. Lond., only son of the late James Broadway, of Cairo, Egypt, aged 28.
- CRESSWELL**.—On Nov. 9th, at Grove Lodge, Winchmore-hill, N., John Cresswell, M.R.C.S., L.S.A. Lond., aged 74.
- MORRIS**.—On Nov. 18th, at Eaton-place, Brighton, John Morris, M.E.C.S., aged 44.
- WILTSHIRE**.—On Nov. 2nd, at Winkleigh, Tunbridge Wells, Thomas Wiltshire, Surgeon, aged fifty-six.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths.

## Medical Diary for the ensuing Week.

### Monday, November 21.

- KING'S COLLEGE HOSPITAL**.—Operations, 2 P.M.; Fridays and Saturdays, at the same hour.
- ST. BARTHOLOMEW'S HOSPITAL**.—Operations, 1.30 P.M.; and on Tuesday, Wednesday, Friday, and Saturday at the same hour.
- ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS**.—Operations, daily at 10 A.M.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL**.—Operations, 1.30 P.M.; and each day at the same hour.
- CHIEFSEA HOSPITAL FOR WOMEN**.—Operations, 2 P.M.; Thursday, 2.
- HOSPITAL FOR WOMEN, SOHO-SQUARE**.—Operations, 2 P.M.; and on Thursday at the same hour.
- METROPOLITAN FREE HOSPITAL**.—Operations, 2 P.M.
- ROYAL ORTHOPÆDIC HOSPITAL**.—Operations, 2 P.M.
- CENTRAL LONDON OPHTHALMIC HOSPITAL**.—Operations, 2 P.M., and each day in the week at the same hour.
- UNIVERSITY COLLEGE HOSPITAL**.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.
- LONDON POST-GRADUATE COURSE**.—Royal London Ophthalmic Hospital: 1 P.M., Mr. W. Lang: Diseases of Iris,—101, Gt. Russell-st.: 8 P.M., Dr. Galloway: Nervous System.—Parke Museum (Margaret-st., W.): 4 P.M., Dr. Louis. C. Parkes: Communicable Diseases.
- CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road)**.—5 P.M. Mr. Lennox Browne: Rhinitis, Acute, Purulent, Croupous, Hypertrophic, Hyperæsthetic (Hay Fever and Hay Asthma), Atrophic; Deformities and Deviations of the Nasal Septum.
- THROAT HOSPITAL (Golden-sq.)**.—5 P.M. Mr. F. G. Harvey: Internal Ear Deafness.
- MEDICAL SOCIETY OF LONDON**.—8.30 P.M. Dr. W. B. Hadden: Syphilis and Nervous Disease in Children.

### Tuesday, November 22.

- GUY'S HOSPITAL**.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
- ST. THOMAS'S HOSPITAL**.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
- ST. MARY'S HOSPITAL**.—Operations, 2 P.M.
- CANCER HOSPITAL, BROMPTON**.—Operations, 2 P.M.; Saturday, 2 P.M.
- WESTMINSTER HOSPITAL**.—Operations, 2 P.M.
- WEST LONDON HOSPITAL**.—Operations, 2.30 P.M.
- ST. MARY'S HOSPITAL**.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same day, 2 P.M.
- LONDON POST-GRADUATE COURSE**.—Hospital for Skin Diseases, Blackfriars: 4 P.M., Dr. Payne: Pityriasis Rubra and General Dermatitis.—Bethlem Hospital: 2 P.M., Dr. Percy Smith: Insanity with Syphilis.—101, Gt. Russell-st.: 8 P.M., Dr. Dakin: Preservation of Perineum.
- ROYAL MEDICAL AND CHIRURGICAL SOCIETY**.—Mr. J. W. Hulke: A case of Hepatic Abscess which burst into the Peritoneal Sac treated by Incision and Flushing; recovery.—Mr. Edmund Owen: The Radical Treatment of Severe Talipes Equino-varus in Children.
- HARVEIAN SOCIETY**.—7.30 P.M. Dinner at the Café Royal.

### Wednesday, November 23.

- NATIONAL ORTHOPÆDIC HOSPITAL**.—Operations, 10 A.M.
- MIDDLESEX HOSPITAL**.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.
- CHARING-CROSS HOSPITAL**.—Operations, 3 P.M., and on Thursday and Friday at the same hour.
- ST. THOMAS'S HOSPITAL**.—Operations, 1.30 P.M.; Saturday, same hour.
- LONDON HOSPITAL**.—Operations, 2 P.M.; Thursday and Saturday, same hour.
- ST. PETER'S HOSPITAL, COVENT-GARDEN**.—Operations, 2 P.M.
- SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN**.—Operations, 2.30 P.M.
- GREAT NORTHERN CENTRAL HOSPITAL**.—Operations, 2 P.M.
- UNIVERSITY COLLEGE HOSPITAL**.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
- ROYAL KNEE HOSPITAL**.—Operations, 2 P.M., and on Saturday.
- CHILDREN'S HOSPITAL, GREAT ORMOND-STREET**.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.
- LONDON POST-GRADUATE COURSE**.—Hospital for Consumption, Brompton: 4 P.M., Dr. C. Y. Biss: Pulmonary Emphysema.—Royal London Ophthalmic Hospital: 8 P.M., Mr. A. S. Morton: Ocular Paralysis.—THROAT HOSPITAL (Golden-sq.)—5 P.M. Mr. T. Mark Hovell: Middle Ear Disease.
- HUNTERIAN SOCIETY (London Institution)**.—8.30 P.M. Dr. S. Mackenzie: Urticaria.—Dr. G. Newton Pitt: The Value of Venesection in the Treatment of Thoracic Aneurysm.

### Thursday, November 24.

- ST. GEORGE'S HOSPITAL**.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
- UNIVERSITY COLLEGE HOSPITAL**.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.
- LONDON POST-GRADUATE COURSE**.—Hospital for Sick Children, Great Ormond-street: 4 P.M., Dr. Colman: Pathological Demonstration on Tuberculosis.—National Hospital for the Paralysed and Epileptic: 2 P.M., Mr. Victor Horsley: Surgical Treatment of Nervous Diseases. London Throat Hospital, Great Portland-st.: 8 P.M., Mr. W. R. H. Stewart: The Causation of Diseases of the Ear.—Central London Sick Asylum, Cleveland-st., W.: 5.30 P.M., Mr. John Hopkins: Cases in the Wards.
- CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road)**.—Dr. Dundas Grant: The Examination of the Organs of Hearing.
- BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-sq.)**.—8.30 P.M. Specimens by Mr. H. Reeves. Dr. Inglis Parsons: Total Absorption of a large Fibromyoma of the Uterus by Apostoll's Treatment.—Dr. F. C. Batcher: Cystic Formations of the Broad Ligament, Diagnosis and Treatment.

Friday, November 25.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.  
LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Bromp-  
ton: 4 P.M., Dr. C. Y. Biss: Hemoptysis.—Bacteriological Laboratory,  
King's College: 11 A.M. to 1 P.M., Professor Crookshank: Erysipelas  
and Suppuration (Streptococci).

CLINICAL SOCIETY OF LONDON.—Living Specimens at 8 P.M.:—Dr. Hadden:  
Two cases of Rhythmical Rocking Movements in Children.—Mr. Storer-  
Bennett: A case of extensive Fracture of the Upper Jaw.—Dr. F. R.  
Walters: A case of Pernicious Anæmia.—Dr. Pitt and Mr. Lane:  
A case of Cranial Cyst. Papers at 9 P.M.:—Mr. Hulke: A case of  
Pancreatic Cyst; exploratory laparotomy; enucleation impracticable;  
death from shock.—Dr. Roper and Mr. W. A. Lane: A case of Ex-  
cision of a Cancerous Stricture of the Small Intestine from a case of  
Complete Obstruction of seventeen days' duration.—Dr. James  
Calvert: A case of Subacute Œdema of Lung occurring above a  
Diminishing Pleural Effusion.

Saturday, November 26.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin De-  
partment, 9.15 A.M.

LONDON POST-GRADUATE COURSE.—Bethlem Hospital: 11 A.M., Dr.  
Theo. Hyslop: Insanity, with Organic Brain Disease.

## METEOROLOGICAL READINGS.

## Notes, Short Comments &amp; Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

## AN UNUSUAL CASE.

A. CORRESPONDENT writes:—"Can any of your readers throw any light upon the following case:—A young lady, aged twenty-three years, up to and about last Christmas was a pale, anæmic-looking girl, breathless upon the least exertion. A series of headaches led to an examination of urine, when it was found that it contained albumen (2 per 1000 Esbach) casts and fat cells. Iron was administered (four grains three times a day), and great improvement in health and appearance ensued. Colour has come to the cheeks and activity and energy have succeeded listlessness and breathlessness. But the amount of albumen has doubled in the time; in fact, it would seem that things improve in direct ratio to the increase of albumen. The heart is only slightly hypertrophied. Diet (milk, fish, starch &c.) is only sparing, yet weight increases."

Dr. John Housley.—We doubt very much whether any such book exists. The means adopted to procure a water-supply for a given village depend but little on the amount of population compared with the topographical, geological and other like conditions involved. Each case, as a rule, must be decided on its own merits, and these are best estimated by an expert water engineer.

Mr. A. T. Brand.—The book has not yet been brought under our notice

## A RECKLESS MEDICAL COMPETITION.

THE Reporter of Ashton-under-Lyne of Nov. 12th contains the following paragraph (the names which are given we have deleted):—

"The spirit of keen competition seems to have at last permeated the medical profession in Dukinfield. A week or two ago Dr. — and Dr. — opened dispensaries in different parts of the town at a charge of one penny a week per member. Now we hear that Dr. — and Dr. — have entered into competition, and commenced dispensaries (in one case next to an establishment run by Drs. — and —) at the small fee of a halfpenny per week membership."

We say little on such a state of matters until we have given the parties concerned an opportunity of explaining their participation in a system which seems disastrous.

Septic must have been aware that there are people so deluded as to believe anything that is improbable and absurd. We know nothing of "electropoise."

M.R.C.S. Eng. is thanked for his communication. He will understand that though we do not publish it, we appreciate it.

## A FORM OF DANDRIF.

To the Editors of THE LANCET.

SIRS,—I have a middle-aged lady under treatment who is suffering from a most troublesome form of dandrif, accompanied by considerable loss of hair, which has existed for years, and as she states she caught it from her husband through wearing his garden hat occasionally, it is probably parasitic. Would any of your readers kindly suggest a form of treatment? Bichloride of mercury has been used as an application both in the form of solution and of pomade (four grains to the ounce).

I am, Sirs, yours faithfully,

Nov. 14th, 1892.

LUX.

P.S.—The husband has derived much benefit from the application of pomade made with lanoline and bichloride of mercury of the strength named, but not until he had lost a great deal of his hair, and even now he cannot get rid of the dandrif.

## FRIENDLY SOCIETIES ABUSED BY THE WELL-TO-DO.

A CORRESPONDENT asks what can be done to prevent tradespeople and others in receipt of good incomes becoming members of provident medical associations "simply for the sake of being medically attended for 6s. per annum." He is surgeon to a "lodge," and has on his list a solicitor's managing clerk (an admitted solicitor), the principal draper, ironmonger, stonemason, a master carpenter, an artist, proprietor of hotel, ditto of several inns, who can all well afford to pay. He says if he declined to attend them the lodge could easily get a fresh surgeon from amongst his neighbours, and he would also lose attendance on their families. He justly observes that what is wanted in the profession is "coöperation."

General Practitioner.—We shall not forget the grievance indicated by our correspondent; but one thing at a time is often the best policy.

Mr. L. Miller.—We do not think our correspondent could do better than refer to the leading article in THE LANCET of Nov. 5th.

## MEDICAL AID ASSOCIATIONS.

Investigator, though objecting to all "sweating," agrees rather with "Verax" than with Dr. Phillips. He thinks the truest words spoken are those by "Fairplay." "It is very much the fault of medical practitioners generally that Medical Aid Associations are able to go on, for if they would keep only qualified assistants and pay and treat them well, the Associations would find difficulty in securing officers or members." He advises a conference of the medical and other officers, and thinks that in this way better terms would be secured. The demand on our space prevents the insertion of this and many other letters.

Surgeon-Major.—We are not aware of any Army Medical Report having been recently published. That for 1890 was reviewed in THE LANCET of July 30th, Aug. 6th and Aug. 18th, 1892.

Mr. Vernon Mossman (Manchester).—We shall be obliged if our correspondent (whose card has been mislaid) will forward us his address.

## SYMPHYSEOTOMY.

At a recent meeting of the Philadelphia County Medical Society Dr. Barton C. Hirst reported a case of symphyseotomy performed on a young woman in the University Maternity Hospital. The operation was successful as regards the mother, and a live infant was readily delivered. It is believed (says the New York Medical Record) that this is the first instance in which this operation, as a substitute for the Cæsarean section, has been attempted in the United States.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Introductory Lecture

MATERIA MEDICA.

Delivered in the University of Edinburgh,

By T. R. FRASER, M.D., F.R.S., F.R.C.P. EDIN.,  
PROFESSOR OF MATERIA MEDICA IN THE UNIVERSITY.

GENTLEMEN,—As we to-day commence a new session, which is contemporaneous with the introduction into our University of several important changes in medical education and graduation, it may be useful if I make some remarks on these changes, especially as this is the first opportunity that has presented itself for my doing so. Briefly stated, the most important changes introduced by the Medical Ordinance, which became law on the 5th of August of this year, are as follows:—1. Certain modifications in the preliminary examination in general education, tending generally to the simplification of this examination, but requiring that the entire examination shall be passed at one and the same time, before medical studies have been commenced. 2. Extension of the minimum course of study for the lower degrees to five years, with a few modifications in the educational and examination arrangements and requirements, the most important of the latter being the addition of mental diseases, ophthalmology, fevers and diseases of children to the curriculum. 3. The substitution of the title "Bachelor of Surgery" for "Master in Surgery," thereby rendering the two lower degrees similar in title; these becoming, therefore, Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.), and being only conferable together and at the same time. 4. The increase in the educational requirements for the degree of Doctor of Medicine and the introduction of an examination for that degree in Clinical Medicine, including some of its special departments. 5. The creation of a higher degree in Surgery, with requirements similar to those for the higher degree in Medicine, to which the title "Master of Surgery (Ch.M.," is to be applied. These changes, gentlemen, are not, however, likely to affect any of you. No doubt the new ordinance provides that every student who began his medical studies before the date when it came into operation shall be entitled to graduate under the system in force before or after that date, according as he shall comply with the regulations of the old or of the new ordinance. As nearly all of you have already entered upon at least your third year of study, it cannot be expected—and indeed the proceeding would be one of more than doubtful wisdom—that you would put yourselves in the position of beginners, and again undergo elementary studies and preliminary and first professional examinations. For you, therefore, the modifications in the curriculum, the institution of a new title for the lower surgical degree, the elevation of the requirements for the degree of Doctor of Medicine and the creation of a new higher surgical qualification are not matters of personal interest.

Indeed, the only provision contained in the new ordinance to which I need draw your attention, as being likely to concern any of you, is set forth as follows: "Subject to regulations to be made from time to time by the University Court, the University may also confer diplomas in special branches of medical and surgical practice on graduates of the University in medicine and surgery." It is undoubtedly the case that specialisation in medical and surgical practice has now become so frequent, and its advantages have been admitted so generally by the medical profession and by the public, that the time has come when the University should assume a definite position towards it. For by doing so it may succeed in limiting the assumption by unqualified persons of claims to special knowledge, in giving a just and adequate recognition to knowledge that has been actually acquired, and in advancing the study of special branches of medical and surgical practice, which require a more extended study than can be obtained in the curriculum for the several degrees in medicine and surgery. These objects might be gained in three ways: by instituting a degree for each special branch; by giving options, embracing the special branches, in the examination for degrees;

No. 3613.

or by conferring diplomas upon candidates who qualify themselves by definite courses of study, and who afterwards pass satisfactory examinations in the special branches. The first method is obviously objectionable, in so far as it would multiply degrees to an extent that would be detrimental to all degrees. The second method would fail in adequately recognising the special knowledge, and would introduce the anomaly of a degree qualifying for practice implying under one and the same title different acquirements in different holders of the degree. These objections do not apply to the third method, as it would not increase the number of degrees or necessitate the existence of degrees implying different acquirements on the part of different holders, while it would adequately recognise the special branch by a special certificate or diploma, for which the course of study could be pursued without interfering with, because subsequent to, the course for a degree. The medical faculty has already expressed the opinion that the following among other subjects might thus be recognised and fostered: ophthalmology, mental diseases, laryngology with aural and nasal surgery, medical jurisprudence, midwifery and gynaecology. Whatever special branch is adopted, the graduate would be required to devote some time, not less than one year, to such further special studies as would entitle him to a certificate in that branch. For the certificate in Ophthalmology, for example, his further studies would require to embrace optics, the anatomy, physiology and pathology of the visual apparatus and systematic and clinical study of eye diseases; for the diploma in Mental Disease, mental philosophy, the laws relating to mental diseases, and the systematic and clinical study of the subject; for the diploma in Medical Jurisprudence, criminal law, morbid anatomy (including practice in post-mortem examinations), toxicology and insanity. The possession of a certificate would, therefore, imply that knowledge had been acquired entitling the possessor to claim special qualifications for the practice of some selected branch of medicine or surgery. The training would become a means for fostering advanced studies in the University, and for forming, with the advanced studies already existing in connexion with theses and about to be instituted in connexion with the higher degrees in medicine and surgery, an Honours School in which higher studies, appropriate for an academic institution, would be conducted.

As I have referred to University Honours, I would express the opinion that it is not advisable to develop further the system of conferring honours on students for mere class or examination distinction, founded upon the work required for obtaining degrees. There is already a danger of diverting the student into too early specialisation, which, while it may lead to great devotion to several of the subjects required for those degrees, also leads to partial neglect of others; a danger which would become increased if special examinations beyond the standard of requirements for degrees were instituted. Such distinctions are not those which a University should place in the first rank. They are, after all, but little removed from schoolboy prizes or the ambitions of a cramming institution. The Honours School rather should be constituted by studies and work performed after the elementary training required for the lower degrees has been completed. Then only can higher studies and researches qualifying for honours worthy of a university be engaged in without interference with the acquirement of that fundamental knowledge which is absolutely necessary for every practitioner of medicine and surgery.

A scheme giving practical effect to this section of the ordinance will, I trust, by-and-by be issued. It will then be open to every graduate in medicine who adopts some special branch of professional work to obtain a high university honour, combined with a guarantee of special qualification to engage in that work. To other provisions in the ordinance I shall afterwards refer; but before doing so I propose to make a few remarks on the subject we are about to commence the study of in this class-room.

Medicine, as a practical Art, may truly be said to consist of only two branches—the knowledge of Diseases and the knowledge of their Cure. This knowledge has a wide foundation. It rests on the sciences of botany, zoology, chemistry and physics; of anatomy and physiology, and of pathology, medical, surgical and obstetrical. Notwithstanding the elevation thus reached, if we regard it merely as a practical art, that art to which you intend to dedicate your lives, then I say that medicine consists of only two branches of learning, one devoted to the knowledge of diseases, the other to the knowledge of remedies. The former teaches how to recognise

diseases, to trace their causes and effects, to anticipate their results; the latter how to recognise and administer remedies, how to ascertain their actions, how to apply these actions to the cure of diseases. Accordingly, in ancient times, when medicine had not yet reached the dignity of a scientific profession, but was an art only, it actually did consist of nothing else than these two departments, called the "Practice of Physic" and the "Materia Medica." Anatomy was all but unknown; chemistry was unborn; physiology was confined to a few crude conjectures about living functions, none of them more resembling the doctrines of the present day than the notion of the Greeks, that the blood swayed backwards and forwards in the veins "like the tide of Eurypus between Attica and Eubœa"; pathology, like chemistry, had no existence even in name; and as for the sciences of zoology and botany, the little known of them was merely some elementary facts comprised in one department of materia medica—that of the natural history of medicinal substances.

The first of the now extant writers on diseases, and the first author on remedies, represented in their works the whole range of the medical knowledge of two thousand years ago; and for many years afterwards their successors did little else than reproduce and variously dress up the observations and doctrines of the famous physicians of Cos and Anazarba. By-and-bye the cultivators of materia medica freed themselves from the trammels of the Greek school. To this result much was contributed by the discoveries of the alchemists and their immediate successors. More attention came to be paid to the physiological action of remedies, to those actions which occur in a state of health as contrasted with a state of disease. At the same time advantage was taken of the advancements that were being made in natural science, especially in chemistry and botany, to improve the description and definition of the articles of the materia medica. The scope of the subject, however, was not altered or its boundaries narrowed. In this University the first professor of the subject, Dr. Alston, in his teaching between the years 1738 and 1760, methodically discussed the natural history of medicines, and their action in health and in disease, with the diseases in which they are used. His successors, Dr. John Hope, Dr. Francis Home, Dr. James Home, Dr. Andrew Duncan and Sir Robert Christison, assigned the same latitude to the subject as it had received under the first occupant of the chair, but also added to it diet in its applications to disease and the therapeutic effects of electricity, galvanism and mineral waters. Indeed, the only curtailment that occurred during these eleven decades of the existence of the chair was when Dr. Cullen, in the session 1761-2, delivered a course of lectures on materia medica, in the interval between the death of Dr. Alston and the assumption of duty by his successor, Dr. Hope. It is not without interest to note that Dr. Cullen almost entirely restricted his teaching to general and special therapeutics, and made only brief and meagre reference to the physical properties of remedies.

I need scarcely tell you, therefore, that from the earliest times Materia Medica has signified the knowledge of healing materials and remedies—the knowledge of all means and circumstances directly or indirectly useful towards the cure of diseases. In the words of my immediate predecessor, Sir Robert Christison, "a complete course of materia medica should treat of: (1) medicines, properly so-called; (2) imponderable remedies or qualities of matter, such as heat, cold, electricity and galvanism; (3) diet, or food and drink, as medicinal agents." Among these several departments the one which, from its special importance and great extent, must engross the largest share of attention is that of medicines properly so-called. Consideration must be given to their chemical, physical and botanical characters, as well as to their physiological properties and effects and uses in disease. While in former times the state of advancement of the various sciences upon which the description and appreciation of the characters and properties of medicines are dependent gave a prominence to the chemical, physical and botanical characters, the present state of science no longer renders it necessary to maintain this ascendancy.

Pathology, after a long and no doubt unavoidably restricted attention to the gross lesions produced by disease, to the modifications of structure caused by abnormal action, or to what may be termed pathological anatomy, has now advanced far into the much more valuable investigation of the changes in normal action leading to or causing these gross changes or producing the conditions which constitute disease. Many important facts have been established in this branch of

pathology, which is now recognised as pathological physiology. The symptoms of several diseases, for example, have been shown to depend on perverted actions of definite portions of the nervous system, on chemical changes in constituents of the body, or on the introduction of hurtful substances, which have themselves been isolated and identified. Physiology has in each of these, and in many other advancements of pathology, acted as an indispensable pioneer, establishing by investigation the normal action and the normal composition of the structures of the body. The problems placed before the physician in each case of disease to which he is required to apply remedies are now, therefore, in many instances more definite and even more simple than they formerly were. Intelligent limitations have taken the place of superstitious or uninformed exaggeration of the curative power of medicines; and it has become apparent that, in order to treat the abnormal conditions with success, knowledge must be possessed of not only the pathological conditions, but also of the exact changes in structure or in composition which the remedial substances are capable of producing. A relatively new department, that of pharmacology, has accordingly been added to materia medica. It constitutes the foundation of therapeutics, or the application of remedies to disease; and as this application constitutes our main work as physicians or practitioners of medicine, the department of pharmacognosy (which deals with the physical characters of remedies) and that of pharmacy (which deals with the forms in which they are administered) must in a sense occupy subordinate positions. Let me add, however, that this subordination is only a relative one. Having regard to the ultimate object of medical study, a knowledge of the physical, sensible and chemical properties of medicinal substances and of pharmacy is of great practical value. Without it much of the advantage to be gained from the study of pharmacology and therapeutics will be rendered unavailable and useless; for the actual administration of remedies is necessarily based on knowledge of the former as well as of the latter.

The subject of materia medica, in so far as it is limited to medicines ordinarily so-called, includes all of these departments; but while the study of the chemical and other physical characters of medicines and of pharmacy should be engaged in at an early part of the curriculum, the study of pharmacology and therapeutics is impossible until a knowledge of physiology and pathology has already been acquired. This subdivision of the subject into two great groups, the physical and the biological, and the placing of the instruction in the former at an earlier period than that of the latter, would prove of much advantage to the student. He would find it a more easy matter to acquire a knowledge of physical and chemical characteristics and of pharmacological processes soon after he had studied botany and chemistry, and while the facts he had acquired of these subjects were yet vividly present in his recollection, rather than many months after the examinations in botany and chemistry had been passed. He would also be in a position to derive more benefit from, and to pursue with greater interest, his studies in systematic and clinical surgery, as he would possess some real knowledge of the remedies constantly being brought under his notice, whose names even he might otherwise never before have heard. The advantages would prove equally great if the departments of pharmacology and therapeutics were placed in a later part of the curriculum. As I have already pointed out, the former is founded upon physiology and the latter upon pathology, and as the separation of their consideration is highly inexpedient—if, indeed, it be not impossible—they cannot intelligently be studied until both physiology and pathology have been mastered. At a later part of the curriculum, further, some knowledge would have been acquired of the diseases which are treated by medicinal substances, and accordingly there would be avoided the perplexities and embarrassments which, in the entire absence of this knowledge, constantly arise from unavoidable references to diseases.

I have referred to the inseparable union that exists between pharmacology and therapeutics, and perhaps some expansion of this statement may be required in addressing an audience for the most part composed of those who now, for the first time, are invited to consider the meaning of these terms. As the object of pharmacological study and investigation is to obtain such knowledge as will enable us, by means of the physiological (or pharmacological) action of remedies, to restore to a standard of normal health the deviations from that standard produced by disease or pathological processes, it would be

highly inconvenient, and would increase greatly the difficulties of accomplishing this object, if the study and teaching of the action of remedies were dissociated from their application. The inconveniences of this dissociation become at once apparent when we realise that it would compel us, as students of materia medica, to ignore such remedial effects as that of salicin in rheumatic fever, of arsenic in chorea, of chrysophanic acid in psoriasis, of ipecacuanha in dysentery, or of iodide of potassium in aneurysm; and to ignore also if not actually the doses of remedies, at any rate the variations in doses necessary to produce different effects in disease and necessary for different diseases. It is, however, impossible to effect this dissociation, for our knowledge of the action of remedies is not only derived from their effects in normal states of the body, but also from their effects in diseased or pathological states, or, in other words, from their therapeutic effects. No description, for example, would be complete of the action of acetanilide, exalgine, phenacetine or phenazone which omitted their analgesic or pain-subduing effects; but this is a purely therapeutic action, not due to any narcotic or anæsthetic pharmacological action, and pain is a manifestation of diseased or pathological processes. No description would be complete of the action of digitalis, squill or strophanthus from which the diuretic action of these substances was omitted; but this action is manifested only in disease, and its demonstration rests upon clinical experience alone. No description would be complete of the action of quinine which did not include its action in reducing abnormally high temperature; but this action is displayed only in fever, and as fever is a pathological condition, the antipyretic action of quinine is necessarily a therapeutical one. No description would be complete of the action of iron which did not include its effects on essential constituents of the blood; but as these effects are produced only in anæmia, and as anæmia is a pathological condition, this, the fundamental action of iron, becomes a therapeutical one.

Influenced by such considerations as I have now brought before you, the Faculty of Medicine and the University Court adopted the recommendations that an examination on pharmacy and on the chemical, botanical and physical characters of medicinal substances should be taken either along with the examination on the subjects of anatomy and physiology, or at any earlier period of examination subsequently to the first professional examination; and that the examination on pharmacology and therapeutics should be taken at the end of the fourth winter of the new five years' curriculum, and after the examination on anatomy, physiology and pathology had been passed. These recommendations are in harmony with the expressed opinions of my predecessor in this chair (Sir Robert Christison), of the General Medical Council, of the Scottish Universities' Commission of 1876, and of the great majority of the teachers of materia medica in Great Britain, and they are supported by the arrangements now existing in the schemes of examination of English universities and of the Conjoint Boards of the Royal Colleges of England and of Scotland. They have been represented to the present Scottish Universities Commission in the form of two proposals: (1) To allow an examination on pharmacy and on the botanical and physical properties of medicinal substances, to be taken as soon after the first professional examination as the candidate desires; and (2) so to arrange the examination in pharmacology and therapeutics as to ensure that the candidate has obtained a sufficient knowledge of physiology before he studies the modifications of physiological conditions produced by medicinal substances, and a sufficient knowledge of pathological processes before the means for restoring them to a normal condition by medicines is required to be considered.

Although the essential parts of these proposals were apparently received with approval by the Commission, for they were reproduced, with at least one bewildering exception, in the first issued medical ordinances, I regret to say that in the final ordinances the Commission has departed from this position, and has, instead, adopted an extraordinary, and in some respects an unintelligible one. The Commission has ordained that the most unnecessary burden should continue to be imposed upon candidates of either maintaining at an examination standard—for two years after the examinations in chemistry and botany have been passed and when studies of totally different kind are occupying his attention—a knowledge of such of the details of these sciences as is required for even the most elementary study of pharmacy and of the

distinguishing physical characters of medicinal substances, or of again laboriously acquiring this knowledge. The Commission has also ordained that candidates shall not be examined in pathology until after they have passed an examination on the therapeutic applications of medicines, which implies that in the opinion of the Commission the modifications of function or of composition by which abnormal or diseased processes and conditions are to be restored to a normal condition by medicinal agencies are to be studied before any knowledge has been obtained of the abnormal or pathological processes themselves.

In order, apparently, that there should be no ambiguity in regard to this extraordinary conception of the relationship between therapeutics and pathology, a most significant word has been introduced into the new ordinance. In the previous ordinance, that under which your studies are being conducted, our subject is termed "materia medica" only. Lest any doubt, however, should exist that materia medica includes therapeutics—although, as I have explained, the history and the very nature of the subject leave no room for doubt—the Commission in the new ordinance has actually changed the designation to that of materia medica and therapeutics. There will, therefore, be no escape from the irrational position of the candidate being examined on the treatment of disease by medicinal agents before knowledge has been acquired of the diseases to be treated, and consequently of the teaching and study of this treatment preceding the possession of this knowledge. This dilemma will occur not only with medicines proper, but also with such therapeutic agencies as electricity, galvanism, foods, mineral waters and climate, for they obviously can be considered here only as means for treating disease. In former years not only did the simultaneous study of pathology and materia medica and the earlier acquaintance with disease, necessitated by a four years' curriculum, greatly lessen the dilemma with regard to medicines proper, but it was largely avoided in the case of the above therapeutic agencies, by postponing their consideration to as late a period of the session as possible, when considerable progress had already been made by the student in his pathological studies. In the future this will be impossible, and the acquirement of knowledge of the therapeutic uses of remedies will then become a mere unintelligent exercise of memory.

You are, gentlemen, to be congratulated that, in so far as your studies in this room are concerned, the new ordinance of the Commission does not apply to you. While I, for my part, look forward with some anxiety to the time when it may be necessary for me thus "to make bricks without straw," I do not forget that any scheme involving new conditions is produced under difficulties, that the statement of defects, even when uncompromising, is often the surest means for effecting their removal, and that the interests of science and of education are those which will ultimately prevail in our University.

## Lectures

ON THE

## PHYSIOLOGY AND PATHOLOGY OF BLOOD DESTRUCTION.

*Delivered in the Examination Hall, Victoria Embankment, on Nov. 22nd, 1892,*

By WILLIAM HUNTER, M.D. EDIN.,  
M.R.C.P. LOND. &c.,

ASSISTANT-PHYSICIAN TO THE LONDON FEVER HOSPITAL; LATE  
SANITARY RESEARCH SCHOLAR, GROCERS' COMPANY.

### LECTURE I. — INTRODUCTION.

GENTLEMEN,—The subject to which I propose to direct your attention in this lecture is a comparatively new one. Blood destruction (*hæmolysis*) has hitherto received too little attention at the hands of both physiologists and pathologists. In this respect the physiologists have been most in fault. Blood formation (*hæmogenesis*) appears to have monopolised their attention to the almost entire exclusion of the process which the necessity for a renewed formation of blood implies—namely, a previous destruction of blood; so much so that

while the literature on the former is voluminous (the organs concerned in this process have even been dignified with a special name, "hæmopoietic") the references to the latter as a normal physiological process are of the scantiest. I am not, indeed, aware of a single paper dealing in any systematic way with the latter. This circumstance renders somewhat more difficult my present task, which is to embody within the compass of this lecture the results of investigations relative to it, which I have now carried on for several years. In the Arris and Gale Lectures before the Royal College of Surgeons in 1889, and in an investigation into the "Pathology of Pernicious Anæmia," published by me in 1888, I had occasion to touch briefly on the subject. I was unable, however, at that time to give it the full consideration I deemed commensurate with its importance. This blank I now propose to fill up so far as I can; and although I am only too well aware how many points have still been left untouched by my observations, I hope that the present contribution to it may serve at least to point out in what directions information is still required; while at the same time it may afford a fresh point of departure for future workers.

#### DEFINITION OF BLOOD DESTRUCTION.

I have spoken of blood destruction as a definite process carried on in health, presumably by certain agencies, in certain situations and under certain conditions, just as blood formation is. That the blood is subject to changes both in its corpuscles and its plasma, necessitating from time to time their renewal, we have every reason, from analogy with the case of other tissues, to believe; and the first question which may naturally arise in your mind is, Why dignify by a special name a process in the blood which in the case of other tissues we are content to let pass without special notice? We do not feel called on to speak of a muscle destruction or a glandular destruction to describe the retrogressive changes which necessarily accompany the activity of these tissues. Why, then, speak of a blood destruction? In answer to this question I ask in return, Why speak of blood formation any more than we speak of a muscle or a gland formation? The reason in both cases is, I think, obvious—namely, first, that the mystery which still shrouds the origin and fate of the blood of itself naturally excites interest and inquiry; and, secondly, the activity of the other tissues is so bound up with the condition of the blood that it is a matter of paramount importance alike to physiologist and pathologist to learn everything they can regarding its life history, its mode of origin, the changes that occur in it and even its manner of death. The slightest deviation from the normal at any period of its life history may carry with it results out of all proportion to the apparent magnitude of the change itself. It will be one of the objects of this lecture to show how true this statement is as regards those series of changes by which the blood in health is affected more or less injuriously, and how an increase in these changes may be, and in certain cases are, responsible for some of the most severe forms of anæmia and blood disease.

#### EVIDENCES OF BLOOD DESTRUCTION DERIVED FROM A STUDY OF PIGMENTS.

Premising that such will be the result of our inquiry, I now ask your attention to the evidence we possess that a destruction of blood is a normal physiological occurrence. The evidence we possess on this point is unfortunately scanty and vague. It necessarily varies according as it is the plasma or the corpuscles that we have special regard to. Here let me say at once that when I speak of the blood I mean not simply an albuminous fluid in which are suspended certain corpuscles, but of a highly organised tissue—a tissue to which I would assuredly and without hesitation apply the term "living" did I not fear to be asked to define what life is. This view of the blood as a tissue is no mere opinion to be accepted or rejected according to the individual standpoint from which its study is approached. It is in my view a cardinal point in the consideration of the physiology and pathology of the blood. The relation of the various parts of the blood—plasma, white corpuscles and red corpuscles—to each other and to certain cells from which they derive their origin are, if anatomically less close, nevertheless physiologically no less intimate than that of the cells and matrix of any other tissue. On this point I would fain, did time permit, dwell. It must suffice now to state that the highly organised nature of the blood of which I speak is evident, in my opinion, not only in the white

corpuscles, but in an equal, if not even greater, degree in the plasma and in the red corpuscles. They are mutually dependent upon each other. No change occurs in the one without being attended by change of some kind in the other. No study of the behaviour of the blood under different circumstances can therefore be complete which does not have regard to this important mutual interdependence of its various elements. These remarks in the nature of a digression are necessary. If in the course of this study I appear to dwell too exclusively on the behaviour of one element of the blood to the apparent neglect of others, I should like you to understand that I do so for some particular reason. If, for example, as will be the case, I speak more of the red corpuscles than of the white, it will not be that I consider the changes in them to be more important than those in the white, but solely that the changes in the blood of which I speak are more easily studied in their case than in the case of the white corpuscles or of the plasma. If I speak much of pigment as an evidence of blood destruction, and study minutely its characters, distribution, mode of formation and ultimate fate, it is not on account of the importance of pigment as such, or of the lesser importance of other products, derived, let us say, from the breaking up of the white corpuscles. On the contrary, most of the changes I describe I shall have to refer back to the action of the white corpuscles or their congeners. My sole reason for dwelling so much on the red corpuscles will be that the points I desired to elucidate I found could best be elucidated by a study of the changes observed in them and in their chief constituent—hæmoglobin.

As I have stated, the evidences of the existence of any special process of hæmolysis in health naturally differs according as we have regard to the plasma, the white corpuscles or the red. In the case of the plasma and the white corpuscles such evidence as we possess, although not unimportant, is comparatively slight. I shall consider it later on, and for the reasons just stated I pass at once to the red corpuscles. Their chief constituent—hæmoglobin—is not disposed of in the same easy way, leaving little or no trace behind, as are the albuminous constituents of the plasma or the white corpuscles. Very early in the scale of animal organisation there appears an organ—the liver—one of whose functions it is to excrete from the body various pigment derivatives of effete hæmoglobin. Important evidence as to the occurrence of a destruction of blood as a normal process is derived from a study of these pigments, either excreted in the form of biliary and urinary pigments or stored up as blood pigment.

#### A. BILE PIGMENT.

As regards the bile pigments the evidence is of two kinds—that pointing to hæmoglobin as their source and that pointing to the liver as the seat of their formation. It will, I think, conduce to clearness if, avoiding detail, I state concisely what the purport of that evidence is. With reference, then, to the derivation of the bile pigments from hæmoglobin, there is, in the first place, the fact, now fully established in my opinion (Virchow, Jaffé, Langhans, Hoppe-Seyler, Cordua and Quincke), that the crystalline pigment—hæmatoidin—so frequently found in old blood extravasations is chemically identical with bilirubin, the chief pigment of the bile; and, secondly, the further fact that some of the pigments which give rise to the characteristic discolourations of bruises are indistinguishable in character and reactions from bilirubin and biliverdin (Langhans, Cordua and Quincke). 1. Under certain conditions therefore, such as those above referred to, the hæmoglobin of the blood undergoes changes leading to the formation of pigments closely resembling, if not identical with, the chief pigments of the bile.

The genetic relationship between hæmoglobin and the bile pigments becomes still more clear when we consider the close connexion now proved to exist (Hermann, Nothnagel, Kühne, Tarchanoff, Stadelmann and Afanassiev) between an increased destruction of hæmoglobin on the one hand and an increased formation of bile pigments on the other. The facts observed in this connexion are of this kind: that when hæmoglobin is injected into or set free in the blood, it is followed by an increased excretion of bile pigments. So immediate and close is this relation that an attempt has even been made (Stadelmann)—hitherto, it is true, with but partial success—to prove that it is quantitative as well as qualitative; that the increase in the excretion of bile pigments is proportional to the quantity of hæmoglobin set free. 2. Hæmoglobin is thus an important source of the bile pigments daily excreted in health.

To what extent this is evidence of a daily hæmolytic process we shall afterwards consider.

### B. BLOOD PIGMENT.

The bile pigments are by no means the only pigment derivatives of hæmoglobin. In addition to the various pigments and chromogens of the urine, some of which are without doubt derived from the bile pigments, while others may, as I think, derive their origin more directly from hæmoglobin, there is another variety whose origin from the blood is so obvious that it has received the name, *par excellence*, of blood pigment. This is the pigment so frequently met with around old extravasations, and as such its characters and the appearance it presents have long been familiar to everyone. It differs from the pigments we have hitherto been considering in two respects—first, that it is usually found in an amorphous or granular form; and secondly, that it retains all the iron of the original hæmoglobin molecule.

The first circumstance enables it to be recognised by means of the microscope, while the second also conduces to its easy recognition and detection, since by suitable micro-chemical methods the iron it contains can be made to give characteristic colour reactions. For the iron present is not organically bound up, as it is in the original hæmoglobin (in which case it is unaffected by such micro-chemical reagents), but it is free, in the form either of its ferrous or ferric salts, or of both, and most probably as an albuminate. In this form it gives all the reactions of free iron, is blackened by sulphide of ammonium, gives the Prussian-blue reaction with ferrocyanide of potassium and dilute hydrochloric acid &c. You will, I trust, have occasion presently to appreciate how greatly the use of such micro-chemical methods facilitates the detection of pigment where otherwise its presence might have escaped notice. Although, as I have stated, the origin of such blood pigment from hæmoglobin is so obvious as to be beyond all dispute, I would not have you believe that the interest connected with it or its genesis is thereby exhausted. On the contrary, around the apparently simple question of the mode of origin of blood pigment from hæmoglobin there raged nearly half a century ago a sharp controversy, taken part in by three of the most distinguished pathologists of the century—i.e., Henle, Virchow and Kölliker. It is not my intention here or now to rake up the ashes of past controversial fires; but in the discharge of my task I cannot but refer to certain points still in dispute regarding this subject of the formation of blood pigment. The consideration of these points I shall take up as they arise in the course of the present study.

*Scope of the Investigation.*—Blood pigment wherever found denotes a death of red corpuscles. The first point in estimating its significance is to ascertain in what situations it is normally to be found, under what conditions, and, so far as is possible, in what amount. Considering in how many situations, and apparently under what diverse conditions, blood pigment may be found such an inquiry may seem a very wide one. In reality, however, when we eliminate all those conditions in which the pigment is obviously derived from extravasated blood, we find that the scope of the inquiry is not so extensive as it at first sight appears. Extensive it no doubt still is; for any conclusion as to its significance, apart from extravasation, must be based upon a comparative study carried out on a large number of animals belonging to widely different classes. At least, so it appeared to me. My observations have therefore been made on animals representative of the different groups of the vertebrata—on rabbits and guinea-pigs, on dogs and cats, on ducks and pigeons, and on frogs, as representing the classes of herbivora, carnivora, birds and cold-blooded animals respectively. It is in my judgment well that the basis of observation was in this way extended; for I found that conclusions drawn from a study of the mammalia alone had to be materially modified in the light of later observations made on birds and amphibians. In no single instance, however, was the information thus gained more definite in its character, or wider in its extent, than was afforded me by a somewhat minute study of the character and distribution of the pigment found in man under different conditions of health and disease. To the results of these observations I will now direct your attention, illustrating the different points by means of photographs and sections thrown on the screen.

*Pigment derived from Extravasated Blood.*—I show you, first of all, sections from three organs—gland, liver and spleen. In each of them, as you will see, there is pigment

present; the gland, indeed, is almost packed full with it, the Prussian-blue reaction being extremely well developed. In the other two the pigment is much less abundant, but I ask your attention to its situation. The liver is markedly cirrhotic, and you see here and there, amidst the thick bands of fibrous tissue, narrow lines of pigment. Its distribution is quite irregular; it has, in particular, no relation to the liver cells. The lines correspond to lymphatics amidst the fibrous tissue. The spleen also shows thickening of its trabeculae and increase of fibrous tissue, especially around some of its larger vessels. Here and there amidst this fibrous tissue you will likewise see small clumps of pigment in form of lines corresponding, as in the former case, to the seat of lymphatics. Lastly, I show you a section of a liver chronically congested (nutmeg liver). In the central zone of the lobule the liver cells are seen to be more or less atrophied and to contain yellow particles of pigment. Unlike, however, the pigment just described, these particles give no Prussian-blue reaction when tested. If they contain iron at all it is not in free form, but is still to some extent bound up. In all these cases the pigment has been derived from extravasated blood. In the case of the gland this is obvious; in the case of the liver and spleen it is no less obvious, and what I ask you to note is that in both cases the pigment is not in relation to the active cells of the organ—the liver cells and the splenic pulp respectively,—but lies amidst fibrous tissue. In the nutmeg liver in which the pigment is in relation to the liver cells I ask you to note, first, that it is the cells of the central zone that contain the pigment, and, secondly, that this pigment does not give the characteristic reactions of free iron. My object in showing you these sections is by way of clearing the ground. In the course of this study I shall have much to say regarding the presence of pigment in the liver and spleen and the significance to be attached to it. I wish you to understand, then, at the outset that in all my further remarks it is not the pigment of extravasation or chronic congestion that I refer to, but to pigment arising independently altogether of either of these conditions, and distinguishable from the latter either by its situation or its character, or by both.

*Situations in which Blood Pigment is found.*—The three organs in which, according to my observations, blood pigment is to be found, independently of extravasation or congestion, are the liver, spleen and red bone marrow; occasionally also the kidney.

### LIVER.

Within the liver blood pigment is found in two situations—namely, the capillaries and the liver cells. Since both its character and the conditions under which it is met with differ in the two cases, it is necessary to consider these two situations separately.

*A. Birds: Within the Capillaries.*—I show you first of all sections of liver from the healthy pigeon. You will note that here and there, distributed apparently quite irregularly throughout the liver tissue, are masses of pigment, some of them of considerable size, all of them giving the characteristic reactions of free iron. The relation of this pigment to the capillaries or cells of the liver cannot in the case of the larger groups be easily made out, since they are frequently surrounded by groups of proliferating connective-tissue cells. The dark golden-brown granules and globules of which these conglomerate masses are made up appear, indeed, at first sight to have no definite relation either to the lobules, to the liver cells or to the capillaries of the liver. In their appearance they call to mind at once the large conglomerate heaps of pigment found so numerously in the livers of frogs—a section of which I now show you by way of contrast. In respect, indeed, of their irregularity in form, size and distribution, these masses might at first glance readily be taken for pigment formed from small local extravasations of blood, the resemblance to such being increased by the small-celled growth amidst which they lie. More careful examination, however, with a view to ascertaining their precise source, reveals that while the smaller heaps lie irregularly within the lobule amidst the liver cells, the larger ones lie in relation to the portal vessels, the small-cell growth amidst which they lie being derived from a proliferation of the connective-tissue cells of the sheath of these vessels. Further, even where no pigment heaps are to be found, you will note that throughout the capillaries of the liver particles of pigment in all respects similar to the individual particles of the larger groups are to be seen lying enclosed within cells of leucocyte nature. The shape of these particles is characteristic. The larger of them are

oval, resembling both in size and shape the original red corpuscles, from which without doubt they take their origin. The long diameter of some of these particles is greater than the breadth of the capillary in which they lie; and here and there at the bifurcation of a capillary such a particle has become arrested. Other particles carried up by cells become arrested behind the point of obstruction; and so by arrest of more and more particles, the larger conglomerate heaps are formed. This accounts for the irregularity in the distribution of these masses, their exact site being determined solely, and so to speak accidentally, by the arrest of the first pigment particle.

Such, then, according to my observations, is the mode of origin of the large heaps of pigment found in the liver of birds in health. The volume and shape of the red corpuscle when converted into pigment determine thus to some extent, according to the above view, the arrest of the particles in the capillaries of the liver. The frequency with which similar accumulations of pigment are found in the liver of animals possessing larger corpuscles than birds should therefore be *a fortiori* greater; and such is the case. Nowhere are such masses of pigment more common than in the liver of frogs. The red corpuscle of the frog has a volume, according to Kölliker, of 9.2 as compared with 1.7 in the pigeon.<sup>1</sup>

In mammals the average diameter is from 0.007 to 0.008 mm. In birds it varies from 0.015 to 0.018 mm., the transverse diameter being a little less than the mean longitudinal diameter, while in batrachians their long diameter varies from 0.015 to 0.058 mm. With such large corpuscles and correspondingly large particles of pigment it is not surprising that, as is the case, the liver of birds and frogs is so constantly the seat of large accumulations of pigment.

*In Mammals.*—In mammals the presence of pigment in this situation is altogether of less frequent occurrence. In young mammals it is, according to my experience, the exception to find it even in the smallest amount. This statement applies more particularly to the rabbit, dog and cat, and also to man. Even when present it is never in such amount as I have shown you in the pigeon; nor does it ever lead to the formation of similar heaps of pigment. In the section I now show you, from the liver of an aged dog, you will see a few pigment particles here and there distributed within the capillaries. The pigment is not free, but lies within leucocytes, occasionally also a few particles being seen within the endothelial cells lining the capillaries. The size of the granules varies much, the largest of them approaching that of a red corpuscle. In many cases part of the pigment appears to be diffused throughout the protoplasm of the cell. As I have stated, pigment in this situation is not unfrequently absent altogether. The younger the animal the less likely is any to be found, and conversely, the older the animal the more abundant is it likely to be. According to my observations age is the factor most important in determining both the presence and the amount of pigment to be found in the liver capillaries of mammals. A gradual increase in its amount does not therefore necessarily imply disease. When met with in old animals it may have a purely physiological significance, one altogether different from that usually ascribed to it. According to Quincke, an increase in the amount of pigment in the capillaries of the liver is an indication of an increased destruction of red corpuscles. I will presently show you that, on the contrary, such an increase, when associated with old age, as it so frequently is, is a sign of lessened destruction. I would not have you suppose, however, that pigment in this situation has always such a purely physiological significance. It may also under certain circumstances have an undoubted pathological significance, pointing to an increased destruction of blood. The diseases in which I find this most strikingly and typically exemplified are pernicious anæmia and malaria. It was a study of the former disease that first led me to investigate the whole subject of blood destruction. You will note from the sections now shown how exceedingly abundant the blood pigment is and how striking the iron reaction can be developed in it. By far the greater part of it lies within the liver cells; but what I wish you now to note is that some of it also lies enclosed in leucocytes within the capillaries. The proportion of pigment in liver cells and capillaries respectively varies very much, I find, in different cases. In some little or none is to be found in the capillaries, notwithstanding that it is abundant in the liver cells. In others, again, it is abundant

in both situations; while, lastly, in a third group, of which my cases furnish me with one example, characteristic pigment granules are present in the capillaries, while the liver cells are almost free. In all cases the pigment lies within cells either leucocytes or cells of kindred nature; occasionally also particles may be found within the endothelial cells lining the capillaries.

Turning now from such changes induced by disease, I show you sections from the liver of rabbits and pigeons, in which a large increase of pigment within the capillaries has been induced experimentally by the injection of toluylendiamine into the circulation. In the case of the pigeon (Experiment 72) you will observe a notable increase in the pigment cells within the capillaries. In the case of the rabbit (Experiment 89) a similar increase is seen, most marked in the capillaries at the periphery of the lobule. The conclusions, then, I would have you carry with you from this portion of our study are as follows:—  
1. One of the situations in which blood pigment may normally (i.e., apart from extravasation or congestion) be found is the capillaries of the liver. 2. The amount present varies much in different animals and under different conditions. While in birds and animals lower in the vertebrate scale its presence, sometimes in large amount, is the rule, in mammals, on the other hand, it is, without being precisely exceptional, nevertheless far from common. 3. The pigment is in health distinguished by the large and varying size of its individual particles, as may be best seen in birds and in the liver of malarial disease. 4. The chief factors influencing its presence in this situation and its amount in health are: (a) the size and shape of the animal's red corpuscles, determining as this does to some extent, first, the mode of death, and, secondly, the size and shape of the largest of the pigment particles. The larger the animal's corpuscles the more likely is pigment to be found. It is hence more common in birds than in mammals. (b) The age of the animal. The amount of pigment tends to increase with age. In young mammals its presence is the exception. (c) Abstention from food and want of exercise. By feeding an animal sparingly, especially if at the same time it be shut up, the amount of pigment in this situation tends, I find, to increase. Thus my observations show that in the livers of pigeons kept shut up for several months it will, other things being equal, be greater than in birds not so confined. It is in this way that the influence of the second factor—age—is to be explained. 5. A considerable increase may take place under pathological conditions as the result of disease, or be induced experimentally by the action of certain agents that destroy the blood. Such an increase is, however, not constant, even in the same animal. Within the liver cells: The capillaries are not the only situation where pigment is to be found within the liver. The liver cells also frequently contain pigment—sometimes, indeed, in far greater abundance.

*In Birds.*—I show you now sections from the liver of the duck and the pigeon. You will note that in addition to the larger particles of pigment present in the capillaries pigment granules of an altogether finer character are seen lying within the liver cells. It is even more abundant in the case of the duck than the pigeon. I ask you particularly to note the size of these granules as compared with those lying within the capillaries. While the latter are large and of varying size, the larger of them having a diameter of as much as 10–15  $\mu$ m., the granules within the liver cells are uniformly small, having a diameter not exceeding 1–2  $\mu$ m. Both varieties give a well-marked reaction of iron. I ask you, moreover, to note that there is apparently no strictly defined relation, as regards amount, between the pigment in the two situations. In some parts pigment is to be seen in the liver cells and in the adjacent capillaries; in others it is abundant in the capillaries and absent or only sparingly present within the liver cells; and lastly—and this is best seen in the duck's liver—it may be abundant in the liver cells, while little or none is to be found in the capillaries.

In mammals the presence of pigment within the liver cells is altogether less common and less marked—at least in health. It is in the form of fine granules, occupying for the most part the cells of the portal zone of the lobule. So small in quantity is it in the rabbit, for example, that the liver tissue gives but a slight reaction when tested with sulphide of ammonium for the presence of iron, instead of the very definite reaction which we have seen in the case of the pigeon and the duck. At least, this is the case unless, as Drs. Brunton and Delphine have

<sup>1</sup> Dictionnaire Encyclopédique des Sciences Médicales, tome vi., Act. Sang., pp. 445–446.

shown, the animal be in full digestion at the time. The same applies to the liver of the dog, the cat and of man. Here, in passing, I may note that throughout my observations I have always attached great importance to the examination of the fresh tissue. The best micro-chemical reagent for revealing the presence of free iron, or iron containing pigment in fresh tissues, is, according to my observations, sulphide of ammonium. A piece of fresh liver tissue placed in sulphide of ammonium takes on a colour varying from light greenish-yellow to coal black, according to the amount of free iron it may contain. If a piece of this tissue be teased out in sulphide of ammonium and examined at once microscopically, the pigment will be seen as coal black spherical granules, or as a diffuse greenish stain, according as it is in the form of granules or diffused in more soluble form amidst the protoplasm of the cell. For the fresh tissue sulphide of ammonium appears to me to be a far more delicate and reliable reagent than, for example, ferrocyanide of potassium and hydrochloric acid (Prussian-blue test). The reaction, if any, is developed at once, and without any injury to the cell protoplasm, whereas with the Prussian-blue test the degree of colour always depends to some extent on the length of time the tissue is allowed to be in contact with the reagent. Hence if, as sometimes happened, the two reagents gave results apparently not in agreement with each other—if, for example, the tissue after hardening gave little or no reaction of iron, whereas in the fresh condition it gave a considerable reaction—it was on the former and not on the latter that I relied most.

This difference in the behaviour of tissues before and after hardening is by no means uncommon. It is most common when the pigment is diffused throughout the cell, and it is due, in my opinion, to the circumstance that in the process of hardening the soluble pigment has diffused out. For this reason the best hardening agent is alcohol, Müller's fluid and other similar preserving agents are to be avoided. Tested in this way, the liver of young healthy mammals gives evidence of containing very little blood pigment. According to Drs. Brunton and Delépine<sup>2</sup> this amount is considerably increased during digestion. If then, as I think is the case, the presence of pigment within the liver cells in health is in mammals by no means a striking feature, the case is very different in certain forms of disease.

*In Disease.*—I show you sections from the liver in cases of pernicious anaemia. You note how very abundant is the pigment; how striking is the iron reaction it gives; and how characteristic is its distribution within the lobule. It lies within the liver cells, but not uniformly distributed amongst all the cells of the lobule. It is most abundant in the cells at the periphery of the lobule, while little or none is to be found in the cells of the inner third of the lobule. These latter are for the most part fatty, and are quite free from pigment. The pigment is in the form of granules, fairly uniform in size, although larger than those we saw in the liver cells in pigeons. It appears to occupy the axis of the rows of liver cells; but on careful examination with high powers it is in some cases seen to occupy a very definite relation to the bile capillaries. It lies close to the edge of the cell, as if in process of being excreted into the bile capillary. In no disease, as I have elsewhere shown,<sup>3</sup> does the amount of pigment found in the liver ever exceed—it rarely ever approaches—that present in pernicious anaemia. A large increase of pigment within the liver cells can, I find, be experimentally brought about by injection of certain substances into the blood. Such an increase I show you in the case of three animals, rabbit (Experiment 42), dog (Experiment 64), and of a pigeon (Experiment 72), induced by the action of tolylendiamine. You will note how exceedingly abundant the pigment is, and how the appearance of the liver contrasts in this respect with that of the liver of the normal animal.

The conclusions, then, to be drawn from this portion of our study are as follows:—1. That another situation in which pigment may be found within the liver apart from extravasation or congestion is the liver cell. 2. The frequency with which it is met here in health, and its amount, differ in birds and mammals respectively. In birds it is usually present, sometimes in large amount. In mammals, on the other hand, while rarely ever absent, it is, according to my observation, not present in any great quantity. 3. The pigment presents certain peculiarities, more especially in respect of the small

uniform size of its granules, which distinguish it broadly from that met with in health in the capillaries of the liver. 4. The conditions under which it arises also differ from those already seen in the case of the latter in the capillaries. (a) The small uniform character of the granules is as striking in birds, where the red corpuscles are large and oval, as in mammals, where they are small and round. (b) It is not increased in old animals. It is, on the contrary, more likely to be found in young animals than in old. (c) Abstention from food and exercise tends rather to diminish its amount. Thus my observations prove that it is not increased by withholding food from animals, or during inanition in man. Drs. Brunton and Delépine's observations show that it is increased during digestion in animals (rabbits). In all these respects therefore the conditions favouring the deposit of pigment in the capillaries and liver cells respectively are essentially different. 5. The only respect indeed in which they are the same is that in both cases I find an increase may take place as the result of disease, or may be induced experimentally by agents acting injuriously on the blood. Even here, however, there is a difference, for the increase which may occur under such circumstances within the liver cells is far greater than anything ever observed in the capillaries. This is true at least of disease.

(To be continued.)

## THE BLOODVESSELS OF THE THYROID GLAND IN GOITRE.

By R. M. HORNE, M.B., C.M. EDIN.

THIS communication is a short account of some work carried on during the present year in the Pathological Institute of the University of Strassburg, under the direction of Professor v. Recklinghausen, to whom I desire to express here my grateful thanks for his uniformly kind assistance and encouragement. Histologists have long pointed out the great richness of the blood-supply to the thyroid gland, and have demonstrated the existence of a comparatively thick media in the walls of its arteries. The morbid histology of the blood vascular system of this gland has been but little worked at,<sup>1</sup> Gutknecht alone of all the inquirers into the pathology of this organ having devoted much attention to it. Working on goitrous thyroids extirpated by Kocher of Berne, he claims to have demonstrated widespread hyaline changes in the walls of the bloodvessels, and also the presence of masses of colloid material in the lumina, both of those with degenerated walls and of those with still normal walls. These colloid masses he derives from the red blood-corpuscles of the circulating blood, in which a complicated series of changes leading to the formation of colloid is described. One is led to infer that these changes are induced by some influence exerted by the diseased thyroid. In the course of this research twenty-eight thyroids have already been examined. These, with one exception, were obtained post mortem. They include seven foetal thyroids removed from foetuses varying in development from between the third and fourth to between the seventh and eighth months; two from new-born children who had died at birth, one being premature about the eighth month, the other a full-time child; one from a child who had died a few days after birth, suffering from bronchitis and icterus neonatorum. The remaining eighteen were derived from individuals varying in age from six months to sixty-eight years, whose deaths had been induced by a variety of causes, comprising, for instance, such widely separated diseases as diphtheria, labyrinthitis purulenta and meningitis, tuberculous affections, asphyxia from drowning &c.

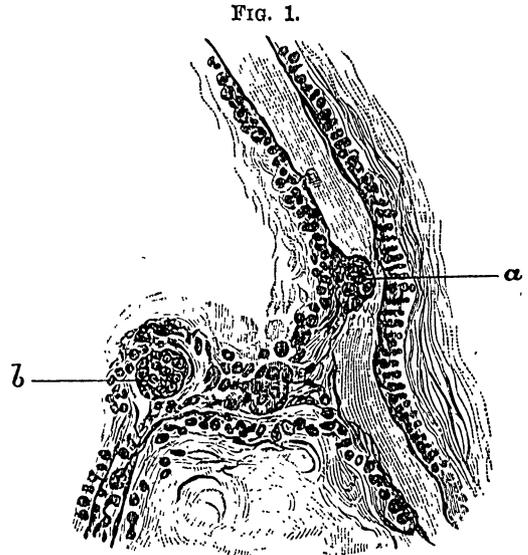

The glands were, with one exception, fixed in Müller's fluid and subsequently hardened in alcohol. The exceptional gland was treated with alcohol only. From these hardened specimens pieces were taken of a size convenient for embedding in celloidin or for cutting with the freezing microtome, which was, however, only occasionally used. Each piece, so far as practicable, was cut so as to contain more normal, preformed thyroid tissue along with

<sup>2</sup> Proceedings of the Royal Society, 1891.  
<sup>3</sup> THE LANCET, Sept. 22nd and 20th, 1888.

<sup>1</sup> Die Histologie der Struma: Virchow's Archiv, Band xcix., 1885.

one or more of the smaller adenomatous nodules. In cases where the nodules were too large to admit of this being done the piece was taken from the remains of the original tissue. In specimens not possessing nodules it is unimportant from what part the piece be taken. The pieces were generally obtained from the periphery of the gland with a portion of the capsule attached, and were cut at varying angles to the long axis of the lobe. The method adopted in the examination of these pieces, with the exception of the few earlier ones, was as follows. The piece was stained *en masse* in alum carmine, and, the excess of colouring matter having been carefully washed away in water, was subsequently hardened in absolute alcohol and then impregnated with celloidin in the usual manner. By this means the confusion so apt to arise between colloid material and celloidin is entirely avoided, as the latter, in contrast to the former, remains quite uncoloured and transparent. Each piece thus treated was cut in series. Serial sections were found to be necessary for the purpose of distinguishing definitely arteries from veins, veins from lymphatics and veins and lymphatics from distended follicles. The recognition of these various structures, often difficult and sometimes impossible from the examination of single sections, is readily accomplished if the structure under examination can be traced through a sufficiently large series of sections. The most important changes found in the course of this investigation are those developed in the arteries. These may best be described by a more detailed reference to one particular case in which they were very pronounced. The gland was removed post mortem from a young man aged nineteen. The section revealed the cause of death to be labyrinthitis purulenta with meningitis. Both lobes of the thyroid were small, and on longitudinal section were seen to be studded with numerous adenomatous nodules of various sizes, and distinctly encapsuled. Some were as large as a cherry, some were scarcely visible to the naked eye, and microscopic examination revealed others not seen macroscopically. Four pieces were taken for examination; three of these were cut in series after being embedded in celloidin; the other was also embedded in celloidin, but not cut in series. One piece only was stained *en masse* before being embedded and cut. Under the microscope the lobules of the gland are well defined and separated from each other by septa of normal fibrous tissue. Many of the gland follicles are composed of a solid group of cells without colloid; some contain a small quantity of colloid with a lining of low cubical cells, others are slightly distended from accumulation of colloid, which has led to a slight flattening of the lining cells. In addition to this—the original and more normal thyroid tissue—are seen circumscribed nodular areas of various sizes, which strike one at once from the depth to which they have taken up the alum carmine. They stand out in strong contrast to the less deeply coloured thyroid lobules. They have pushed aside the thyroid follicles in their growth, from which the older ones, at any rate, are separated by a capsule of fibrous tissue often containing many elastic fibres. The tissue composing the nodules is thyroid in its nature and represents the tissue of that gland in its various stages of development, from the branched, elongated, solid groups of cells through the stage in which the cells are arranged in round solid groups to the appearance of ordinary follicles containing colloid. In the older nodules the follicles become much distended and rupture of the walls between adjacent follicle is frequent, the cells, however, still retaining their cubical shape. The cells which build up these various structures in the nodule are much more deeply coloured than the cells of the normal thyroid follicles, and it is to these of course that the deep colour of the nodule as a whole is due. There are many other small, deeply stained areas to be seen which with low powers might in many cases be regarded as nodules in their youngest stage, but which with higher powers are found to be altered arteries. The alteration which these arteries have undergone consists of a well-marked proliferation of their endothelium in localised areas, so as to form solid buds of cells projecting into the lumina of the vessels in which it occurs. Such a condition has not previously been described in the arteries of the thyroid, or, so far as I am aware, in the arteries of any other organ. A typical example of this bud-like proliferation is seen in Fig. 1 (a), in which an artery is shown in longitudinal section. The three coats of the artery are easily traced throughout its whole course. The media is particularly well marked, consisting of several layers of muscle cells in transverse section, and here and there on the intima flat endothelial

cells are to be seen. At one point of the intima (a) there is a very evident projection into the lumen of the vessel. This is composed of a group of small, round or slightly polygonal, closely-packed cells, which stain well with alum carmine. The muscular coat passes entirely outside of this projection and is almost unaffected by it; perhaps slightly deflected to one side. The group of cells lies without doubt quite internal to the media in the intima itself, and can only have been developed by proliferation of the endothelial cells at that point. The innermost layer of cells—i.e., those towards the lumen—still retain their elongated, flattened endothelial character, but are larger and more distinct than normal, and form a continuous

covering over the projecting bud. The effect of this projection is evidently to considerably narrow the lumen of the vessel at the point where it is situated. In this section the lumen is reduced to a very narrow channel. The circulation has not been brought to a standstill thereby, as the vessel behind and beyond the bud is still filled with normal red blood-corpuscles. In a branch given off by this artery several such buds are found just at its commencement, although, owing to the obliquity of the section, their relation to the various coats of the vessel is not so satisfactorily shown. One bud (b) is seen lying free in the lumen, circular in shape and consisting of

FIG. 2.

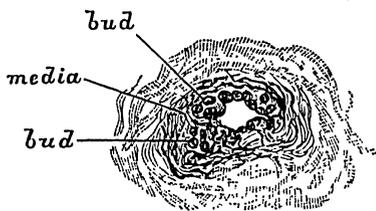

small round or polygonal cells surrounded by a layer of more endothelial-like cells.

In Fig. 2 another artery is shown in longitudinal section in which the bud-like proliferation of the endothelium is well displayed. This artery is remarkable for the number of buds present in the short length of vessel depicted. The buds themselves in their structure and position resemble that of Fig. 1. At several points also a commencing proliferation of endothelium is visible, which has not yet developed into a well-defined projection. The diminution in the size of the lumen is very evident. Transverse and oblique sections of

arteries with similar bud-like endothelial proliferations are naturally to be met with much more frequently than such beautiful longitudinal sections already figured, but are none the less characteristic. Two transverse sections are shown in Figs. 3 and 4. In the first of these the resolution of the wall into its three components is easily made, and there are seen to project from the intima two small rounded groups of cells resembling the buds already seen. In Fig. 4 the media is not so readily distinguished, but by following the vessel through a few sections all doubt of its arterial nature is removed. There are present in this section two projecting masses of cells: one is large and consists of cells similar in size and shape to those of the buds seen in longitudinal section, the innermost also partaking more of the nature of true endothelium, although in part of the margin they are more rounded than elongated. The other bud is much smaller, contains fewer cells, and is probably a younger stage of development. The endothelium lining the rest of

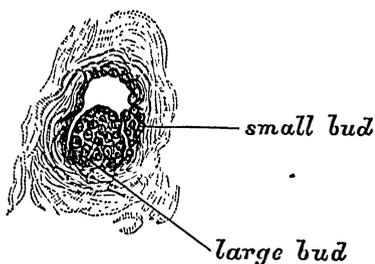

FIG. 3.

the lumen is well developed and almost resembles a low cubical epithelium. The lumen, although blocked to some extent by these buds, is in neither case completely closed, but still admits the passage of blood, normal red blood-corpuscles being present in both sections. Transverse sections of arteries displaying a more complete occlusion of the lumen than is here represented are readily found. What part is played by collapse of the walls of the vessel in this diminution in the size of the lumen it is difficult to determine. It would seem, however, to be small, for in most cases if the buds be supposed to have been removed there would remain a lumen large in proportion to the size of the vessel in which they are situated.

Perfect occlusion of arteries has not been satisfactorily demonstrated in this gland, but in one other it is frequently met with. In this specimen the lumen is filled with a mass of cells which cannot be resolved into bud-like pro-

FIG. 4.

jections. The cells resemble in size and shape those of the gland follicles, but stain somewhat more deeply. As it is often impossible to determine the presence of muscle cells in the wall of these occluded vessels, it becomes a matter of great difficulty to differentiate them from normal thyroid follicles. The difference in the depth of colour leads one to suspect their nature, but this can only be finally determined by tracing through a series of sections their connexion with the still functional arterial system.

While the proliferation of endothelium is generally directed inwards towards the lumen in the form of rounded buds, it is not always so. The groups of cells may cause little or no projection of the intima, but may develop outwards at the expense of the muscular coat, which is then only with difficulty, and sometimes not at all, to be followed at this point. Or again, as seen in some of the transverse or oblique sections of the smaller intra-lobular arteries, the proliferation is more general

and forms several irregular layers of deeply coloured cells surrounding the whole circumference of the lumen. The size of the buds varies much within certain limits. A size often met with is seen in Fig. 4. Larger buds than these are occasionally found, and buds of all sizes between these and a slight elevation consisting of two or three cells occur. It is probable that the enlargement of single endothelial cells indicates the commencement of the process. In connexion with their significance and ultimate fate it is of importance to learn if the buds become detached from the wall of the artery from which they have sprung, to be carried along in the blood stream. Attention has therefore been directed to discovering any indication of such a narrowing of the base as would be expected to occur as the natural preliminary to a detachment of the bud in its entirety. No evidence of this has been observed. On the contrary, the buds, rounded or conical, possess a base as great, or almost as great, as any other diameter parallel to the base. Attempts have also been made by tracing in either direction transverse sections of buds (such, for instance, as *b* in Fig. 1) lying free, in transverse sections of arteries, to determine if they were free throughout. The presumption of course is that these are merely sections of the projecting ends of buds which have their base of attachment at a lower level than the plane of section. My observations confirm this view. It is therefore concluded that detachment of the buds in their entirety does not occur. It is possible, however, that individual cells are thrown off into the blood stream. Cells larger in size and more regular in shape than normal white blood-corpuscles have occasionally been seen lying free in the lumen of an artery, and may possibly have come from one or more of these buds. This is a point demanding further investigation.

One can scarcely avoid being struck by the resemblance between many of these buds and young gland follicles. The interesting question, then, naturally presents itself: Does colloid ever occur in the interior of a bud? Sections of arteries have been found in this thyroid having buds which contain in their interior colloid not to be distinguished from the colloid in the true gland follicles. From each of three other thyroids also a section of an artery having a bud with colloid in its interior has been obtained. The occurrence of such buds though rare is positive. It would seem therefore that they possess, in common with true thyroid follicles, the power of secreting or of producing colloid material.

It remains for me to decide the frequency of the occurrence of these proliferative changes—(1) in the arteries of this particular gland; (2) in the other glands examined; and (3) finally to determine whether this condition is confined to the arterial system. It has already been stated that four pieces were taken from this gland for microscopical examination. In all of the sections made from these, numbering over two hundred, arteries presenting the condition described were to be found with the utmost facility. It is not an over-statement to say that the majority of the arteries in many of the sections were so affected. The condition is evidently a widespread one. But while this is so, it has also to be remarked that the larger arteries are almost or altogether free from any such proliferative changes. It is in the smaller arteries, whether extra-lobular in the inter-lobular septa, or intra-lobular in the inter-follicular septa, that the condition is most frequently seen. It also occurs in some of the arteries in several of the nodules. The buds may develop at any part in the course of a vessel in which they are liable to occur, but are as a rule most frequent at the points where branches are given off, or in the branches themselves at their origin. In all of the eighteen more fully developed glands the same proliferative changes in the endothelial lining of the arteries have been observed to a greater or less extent, arteries so altered being generally found without much difficulty. Of these eighteen glands, eleven presented one or more adenomatous nodules in one or other lobe. The remaining seven, although not containing nodules, were more or less enlarged, the enlargement in all probability being either due to an accumulation of colloid in the follicles—shown in five of the seven and especially well-marked in one case of extreme enlargement—or to an increase in the number of follicles themselves. Of these, one was removed from a girl two years and a half old, who had died of catarrhal pneumonia. The enlargement was only slight. Sections of arteries having bud-like proliferation of their endothelium have been distinctly demonstrated, but occur rarely. The other belonged to a six months' old child. The gland was enlarged in both lobes. On microscopic examination the alteration in the arteries is frequent and pronounced.

No colloid is present in the follicles of either of these two glands. One thyroid was obtained from a woman aged fifty-eight, in whom a slight exophthalmos was present. The cause of death was pneumonia. Both lobes of the gland were enlarged, the right much more than the left. The large size of the right lobe was seen on section to be due to several large colloid degenerated nodules—one of them cystic—which had reduced the original tissue to a minimum. In the left lobe several smaller nodules were also observed. In most of the sections made from the more normal part of the right lobe, as well as in those made from the left lobe, many arteries with bud-like proliferation of their endothelium were present. In the three thyroids obtained from new-born children the same changes were found, in varying degree. In that of the premature child, and in that of the icterus neonatorum case, it was only after the examination of numerous sections that distinct evidence of endothelial proliferation in the arteries was gained; in the other case, however, arteries so altered were present in the greater number of sections made. This gland was slightly enlarged. It was difficult to decide whether enlargement was present in the other two. Careful section of all three did not display any nodules.

Of the seven fetal glands examined, arteries having buds have been satisfactorily demonstrated in four, doubtfully in one, and not at all in the remaining two. In none of the four glands in which such arteries are found does the condition occur with the frequency associated with most of the other glands examined. One of these, removed from an anencephalic foetus, was decidedly enlarged in both lobes, no nodules were observed macroscopically or microscopically, and no colloid in the follicles. A large number of sections were made from this specimen, but in only a few were altered arteries found. As to the distribution of this proliferative change, great pains have been taken to determine whether it is confined to the arterial system. Without going into details it will be sufficient to state that no evidence of its occurrence in the endothelial lining of the veins has been obtained. My observations on the capillaries do not as yet admit of any definite conclusions.

It is not my intention to enter into a discussion of the bearing which these observations may be supposed to have on our views of the physiology and pathology of the thyroid. A more extended investigation of the various points here cursorily dealt with is necessary before any general conclusions can be based upon them. I am at present carrying on this research in the laboratory of the Royal College of Physicians, Edinburgh.

Slamanan, Scotland.

## A REPORT OF TWENTY-TWO CASES OF INTUBATION OF THE LARYNX.

By JAMES B. BALL, M.D., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN, AND PHYSICIAN TO THE THROAT DEPARTMENT, WEST LONDON HOSPITAL.

Of the twenty-two cases of intubation of the larynx here reported sixteen occurred under the care of some of my colleagues at the West London Hospital, and the remaining six were cases in private practice to which I was called by the medical men who were in attendance. The majority of the hospital cases I was enabled to follow throughout, owing to the courtesy of my colleagues, to whom I am also indebted for permission to publish the cases. All the patients were children, and they ranged in age from thirteen months to eight years. Of the twenty-two cases ten recovered. Intubation was performed in every case for symptoms of acute laryngeal stenosis which threatened the life of the child, and as the alternative of tracheotomy. In two cases the laryngeal trouble arose from traumatic causes—in one from swallowing very hot tea, in the other from swallowing carbolic acid. The rest were cases of laryngitis, simple or membranous (diphtheritic); it was not always possible to determine which. In five cases the disease was secondary to measles. Four of these died. In seven cases tracheotomy was performed after intubation had been tried, principally because the tube seemed to be clogged with membrane or secretions. All of these died.

In the cases which recovered the tube was left in the larynx for periods varying from three to thirteen days, the average period for the ten cases being eight days. The thread was

allowed to remain *in situ* in four cases, and in one of these it is noted that the child dragged the tube out by its means. In the rest of the cases the thread was removed immediately after the introduction of the tube. In all my own cases I removed the thread at once, and I have no doubt it is the best plan. In two cases (Cases 13 and 15) an ulcer was found post mortem on the anterior wall of the trachea, at a point corresponding to the position of the lower end of the tube. It is only right to mention that the tubes used in these cases were not constructed in accordance with O'Dwyer's later patterns. Case 16 is an instance of "death on the table," a rare occurrence with intubation. I have no intention here to make any remarks on the value of intubation or on the relative merits of intubation and tracheotomy. I will merely say that in two of my own cases (Cases 17 and 21), both of which recurred, tracheotomy had been previously recommended as the only chance of saving the child's life, and had been declined by the parents owing to the slender hope which was offered even if the operation were performed. In both of these cases they gladly consented to the mild and bloodless operation of intubation, although I only held out an equally slender hope of recovery. In this way I am sure that some lives may be saved by intubation which would otherwise not be saved, and, moreover, the operation is not so likely to be deferred until the child is *in extremis*, as tracheotomy too often is.

The following is a brief epitome of the notes taken. The sixteen cases first in order are hospital ones.

CASE 1.—Boy aged two years. Admitted to hospital on July 26th, 1889, under the care of Mr. Weiss, for a scalded throat, caused by drinking almost boiling tea. Marked signs of laryngeal obstruction. Intubation was performed on the evening of the 26th; immediate relief. Fed by enemata only. Tube removed on the 29th. No return of dyspnoea. Recovered.

CASE 2.—Boy aged four years. Admitted to hospital on July 27th, 1889, under the care of Dr. Drewitt, with a history of having swallowed about a teaspoonful of carbolic acid. Some hours after admission marked signs of laryngeal obstruction supervened. Intubation was performed. The laryngeal symptoms were relieved, but the breathing became very rapid and the child more and more cyanosed. Died on the following day. At the post-mortem examination there were found ulceration of the pharynx, slight gastritis and broncho-pneumonia.

CASE 3.—Boy aged four years. Admitted to hospital on Oct. 16th, 1889, under the care of Dr. Drewitt. Had been ill a week. Diphtheritic membrane was present on tonsils. There was considerable laryngeal dyspnoea. The urine contained albumen. Intubated on the evening of admission. On Oct. 17th the tube was coughed up, together with a long membranous cast from the trachea. Dyspnoea soon returned and the tube was reintroduced. On Oct. 19th marked signs of broncho-pneumonia appeared, the temperature rising to 102° or 103° on this and subsequent days. The tube was removed on Oct. 20th, but had to be replaced. On Oct. 23rd the tube was coughed up, and as the breathing continued easy it was not again replaced. The lungs gradually cleared and the child recovered.

CASE 4.—Girl aged two and a half years. Admitted to hospital on Aug. 25th, 1890, under the care of Dr. Drewitt, with symptoms of bronchitis and laryngitis, which had existed for two or three days. Intubation was performed soon after admission, with immediate relief of the laryngeal dyspnoea. The tube remained *in situ* until Sept. 1st, when it was removed and was not further needed. The bronchitis gradually cleared up. Recovered. Two months later this child was readmitted with similar symptoms, was intubated and recovered.

CASE 5.—Boy aged one year and ten months. Admitted to hospital on Oct. 19th, 1890, under the care of Dr. Hood, with marked laryngeal dyspnoea. The child was much cyanosed on admission. No membrane visible in the pharynx. Intubated immediately, with complete relief. The tube was coughed up in the night and was immediately replaced by a larger size. During the following days the tube was removed twice, but had to be replaced on account of the dyspnoea. On Oct. 31st the tube was finally removed. On Oct. 30th signs of broncho-pneumonia set in, which ran a course of ten or eleven days. Recovered.

CASE 6.—Girl aged four and a half years. Admitted to hospital on Oct. 21st, 1890, under the care of Dr. Hood. She had suffered from symptoms of laryngitis for two days. On admission she was cyanosed, and had marked recession of lower ribs on inspiration. No membrane in the pharynx. Urine contained a trace of albumen. Intubated at once with

complete relief. The tube was removed on the 23rd, and again on the 26th, but had to be replaced. On the 31st the tube was finally removed. Recovered.

CASE 7.—Boy aged four years and eleven months. Admitted to hospital on Oct. 28th, 1890, under the care of Dr. Herringham. The child had measles a week previously, and a croupy cough and stridulous breathing for three days. There was much swelling of the glands of the neck and diphtheritic membrane on the tonsils. Intubated immediately, and was relieved for a time. On the morning of the 29th the child pulled the tube out by means of the thread, which had been left *in situ*. It was replaced immediately. The breathing, however, became worse. Tracheotomy was performed, but the child died in the course of the day.

CASE 8.—Girl aged two years and three months. Admitted to hospital on Oct. 31st, 1890, under the care of Dr. Drewitt. She had measles a week previously. Breathing was bad for three days. Marked signs of laryngeal obstruction. Intubated soon after admission. Was relieved for a time, but much mucus collected in the throat, which the child did not seem able to clear away by coughing. Crepitation in both bases. Temperature rose to 104°. Tracheotomy was performed, with temporary relief. The child died next day.

CASE 9.—Boy aged three years and two months. Admitted to hospital on Nov. 11th, 1890, under the care of Dr. Hood. The child had measles ten days previously. Croupy cough and gradually increasing dyspnoea for three days. On admission there were signs of severe laryngeal obstruction. No membrane was seen in the pharynx. Urine contained albumen. Intubation was performed at once. Continued easy until Nov. 14th, when broncho-pneumonia developed. The breathing became more difficult. Tracheotomy was performed on Nov. 15th. The child died on the 17th.

CASE 10.—Boy aged four years. Admitted to hospital on Nov. 12th, 1890, under the care of Dr. Hood. The child had difficulty of breathing for three days. On admission he was cyanosed, and had signs of marked laryngeal obstruction. No membrane was seen in the pharynx. He was intubated immediately, and seemed much relieved for a time. On Nov. 13th the breathing had become more laboured. Tracheotomy was performed, but without apparent relief. Died on Nov. 14th.

CASE 11.—Boy aged three years. Admitted to hospital on Jan. 24th, 1891, under the care of Dr. Herringham. The child was perfectly well until the previous evening, when difficulty of breathing set in rather suddenly. On admission there was stridulous breathing. There was no membrane in the pharynx, and no albumen in the urine. On the evening of admission the dyspnoea had increased so much that intubation was performed. The child continued comfortable after this. The tube was removed on several subsequent days, but had to be replaced on account of return of the dyspnoea. On Feb. 6th the tube was finally removed. Recovered.

CASE 12.—Girl aged two and a half years. Admitted to hospital on Jan. 25th, 1891, under the care of Dr. Herringham. The child had not seemed well for a week. There had been difficulty of breathing for two days. Diphtheritic membrane was present on the tonsils. The urine contained albumen. The dyspnoea gradually increased and intubation was performed on the evening of admission. Relief was obtained for a time, but on the following day the tube seemed much clogged. It was removed, washed and replaced, but soon seemed clogged again. On the morning of the 27th tracheotomy was performed. The patient was relieved for a time, but she died the same evening.

CASE 13.—A girl aged thirteen months. Admitted to hospital on March 15th, 1891, under the care of Dr. Herringham. She had suffered from a croupy cough and noisy breathing for two days. On admission there was marked laryngeal obstruction and some lividity. There was no membrane to be seen. Intubation was performed soon after admission. The tube was coughed up on this and the following day, but had to be reintroduced owing to dyspnoea. During the two following days signs of broncho-pneumonia developed, and the child died on the night of the 18th. At the post-mortem examination no membrane was found anywhere. On the anterior surface of the trachea, corresponding with the position of the lower end of the tube, was a small round ulcer. There was another superficial ulcer on the anterior wall of the larynx, at the level of the cricoid cartilage.

CASE 14.—A boy aged two years and eleven months. Admitted to hospital on Feb. 24th, 1892, under the care of Dr. Herringham. He had suffered from difficulty of breathing for

a few days previously. On admission there were marked laryngeal obstruction and lividity. Intubated immediately. The patient died on Feb. 25th. On post-mortem examination membrane was found to be present in the larynx, trachea and bronchi.

CASE 15.—Boy aged one year and five months. Admitted to hospital on Feb. 26th, 1892, under the care of Dr. Hood. The child was suffering from severe laryngeal dyspnoea. Patches of diphtheritic membrane were visible in the pharynx. He was intubated immediately. The tube was coughed up after two hours and replaced at once; it was also coughed up again next day and on the day following. On the latter occasion it was replaced by a larger tube. On the evening of the 28th the dyspnoea increased. Several pieces of membrane were coughed up, but the tube seemed to be more or less blocked. Tracheotomy was performed, when the breathing became easier for a time. The child died on Feb. 29th. On post-mortem examination membrane was found in the larynx, trachea and bronchi. On the anterior surface of the trachea, opposite the position of the lower end of the intubation tube, was a small, round, superficial ulcer.

CASE 16.—Boy aged one year and five months. Admitted to hospital on Feb. 1st, 1892, under the care of Dr. Herringham, for chronic diarrhoea. On March 5th measles developed. On the 10th a croupy cough and some laryngeal obstruction were present. There was no membrane in the pharynx. On the 11th the dyspnoea had increased very much and intubation was performed by the house surgeon in charge. The tube was only introduced after a somewhat prolonged attempt, and the child had by this time ceased to breathe. The tube was at once drawn out by means of the string. Artificial respiration was resorted to and subsequently tracheotomy, but the child did not breathe again. On post-mortem examination no membrane was found in the larynx, trachea or elsewhere.

The remaining six cases came under my own care in private practice.

CASE 17.—Boy aged two years and three months. I was asked to see the case by Dr. Denton of Brixton on Feb. 26th, 1890. The child had a croupy cough for five days, and some laryngeal stridor for three days. No membrane was visible in the pharynx. The symptoms of laryngeal obstruction did not seem sufficiently urgent at my first visit to interfere, I was summoned on the morning of the 27th, when the laryngeal dyspnoea was very urgent. I performed intubation, and immediate relief followed. The tube was removed on March 3rd, but the dyspnoea returned in about an hour and I had to replace the tube. An attempt was made to dispense with the tube on March 5th, 7th and 10th, but on each occasion it had to be replaced. It was finally removed on March 12th. The child recovered.

CASE 18.—Boy aged thirteen months. I was asked to see the case by Dr. Starkie of Sussex-street on March 26th, 1891. The child had been suffering from whooping-cough for a month. Croupy symptoms had existed for two days. He was somewhat cyanosed and presented marked signs of laryngeal obstruction. I performed intubation and immediate relief followed. On March 27th the temperature rose to 104° and signs of broncho-pneumonia appeared. The pneumonia became extensively developed throughout both lungs during the following two days, and the child died on April 1st. The tube was not disturbed after its insertion, and the child breathed freely through it up till the time of death.

CASE 19.—Boy aged five years. I was called to see the case by Dr. Starkie on Nov. 16th, 1891. The boy had been suffering from broncho-pneumonia, from which he had recovered about a week. He had hoarseness and croupy cough for three days and some laryngeal stridor since the previous day. When I saw him there was very marked laryngeal obstruction. There was no membrane to be seen in the pharynx. The urine contained albumen. I performed intubation and the dyspnoea was immediately and completely relieved. On Nov. 19th I removed the tube and it did not require to be again inserted. Recovered.

CASE 20.—Girl aged eight years. I was asked to see the case by Mr. Reinhardt of Batterssea on Feb. 13th, 1892. She had suffered from croupy cough and laryngeal dyspnoea for three days. There were diphtheritic membrane on the tonsils, much infiltration of the lymphatic glands of the neck and the urine contained albumen. There were signs of severe laryngeal obstruction and the child was considerably cyanosed. I performed intubation, and the breathing was completely relieved and continued so until the following day, when the child died rather suddenly after a fit of coughing.

CASE 21.—Boy aged six years. I was asked to see the case

by Mr. Sequeira and Mr. Jones of Leman-street on April 22nd, 1892. The boy had just recovered from measles and had croupy symptoms for four days. A fatal case of diphtheria had occurred in the house in which the child lived five weeks previously. There was no membrane to be seen in the pharynx. The urine contained albumen. The signs of laryngeal obstruction were very marked. There were fine râles at both bases. Temperature 103°. I performed intubation, with immediate relief of the laryngeal symptoms. During the following days extreme broncho-pneumonia developed, but the laryngeal breathing continued easy. The tube was removed on April 28th, and did not need to be replaced. The pneumonia ran a severe and prolonged course, but the child ultimately recovered.

CASE 22.—Boy aged one year and eleven months. I was asked to see the case by Dr. Shaw-Mackenzie on July 23rd, 1892. The child had suffered from croupy cough and gradually increasing laryngeal dyspnoea for three days. There was no membrane in the pharynx and no albumen in the urine. The signs of laryngeal obstruction were very urgent. Intubation was performed, with immediate relief. The tube was removed on July 28th, but the dyspnoea became so severe after a couple of hours that it had to be replaced. It was finally removed on July 30th and the child recovered.

Wimpole-street, W.

### "ABDOMINAL SECTION IN CERTAIN CASES OF PELVIC PERITONITIS."

By G. ERNEST HERMAN, M.B., F.R.C.P. LOND.,  
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL ETC.

IT was my intention to take part in the discussion at the Obstetrical Society on Dr. Cullingworth's paper under the above title, but I was obliged to leave before the end of the meeting. The paper was a most valuable contribution to our clinical knowledge of inflammation of the uterine appendages. Its value lay in the features—first, that it was a plain record of every case, without selection; secondly, the cases occurred in a public hospital under the eyes of keen critics, so that Dr. Cullingworth was guarded against deceiving himself either as to the gravity of the symptoms before operation or the reality of the relief afterwards; thirdly, in relating the results, survival from the operation was not taken as cure, and there were no such phrases as "cure," "the happiest results" &c., but the patients were watched as long as possible, and the patient's actual state was given. I know of no publication in this country of so large a number of cases observed and reported in this accurate and complete way.

Some of the criticisms of the paper were inconsistent. It was urged that the mortality from pelvic peritonitis and from inflammation of the tubes was much smaller than Dr. Cullingworth's operative mortality; and at the same time the title was found fault with, because in so many of the cases there were tumours or abscesses. The latter fact made the former criticism not apply. Then Schmalfuss's valuable paper was quoted as bearing on the subject, but his operations were performed for "castration for neuroses," and in Dr. Cullingworth's paper there was not a single case in which the operation was done for a neurosis. This is important, because it explains the high death-rate as compared with the statistics of some other operators. In operations for the removal of the uterine appendages there is an inverse relationship between the death-rate from the operation and the proportion of cures. An operator who removes a great number of almost healthy tubes and ovaries for pain and other nervous symptoms will have a low death-rate from the operation, but a great number of failures to cure; whereas one who, like Dr. Cullingworth, only operates on cases believed to have serious organic disease will have a higher death-rate from the operation, but a large proportion of permanent cures. With regard to the question of cure, a discussion in Paris is reported in the *Annales de Gynécologie* for 1891, in which seven French surgeons brought forward lists of cases in which they had followed up the after-histories of the patients. Added together these comprised 288 cases, with 230 permanent cures, or 82 per cent. of cures and 18 per cent. of failures. Without complete details I cannot say that these cases were strictly comparable to Dr. Cullingworth's, but they are probably more comparable than those of Schmalfuss.

This paper was not brought forward that we might admire Dr. Cullingworth's diagnostic and operative skill, but to influence practice. The propositions laid down at the end are the important part of it. I can from my own experience confirm Dr. Cullingworth's statement that in suppurated ovarian cysts the temperature is often normal. I exhibited to the Obstetrical Society a specimen which supported Proposition 14. I doubt the correctness of Proposition 11; for I think the most common cause of pelvic peritonitis in the virgin is catarrh of the genital passage extending along the tube to the peritoneum. Such cases generally end in complete and permanent recovery, so that this view of their pathology is not verified; but cases admitting of this interpretation are, in my experience, far more frequent than tuberculous disease. Proposition 3 is the one which, if accepted, will have the largest influence on practice; and here I regret that I cannot follow Dr. Cullingworth. I do not think that the sooner surgical treatment is carried out the better; for I am sure that many (not all) cases in which there are distinct swellings in the posterior quarters of the pelvis, and there have been recurrent attacks of pelvic peritonitis, will get practically well if they are given sufficient rest in bed, combined with other proper treatment. In illustration I may refer to Case 31, in which the result was most satisfactory; but the patient had been in hospital only two days when the operation was done, and the conditions found were such as tend to recovery when the patient is under favourable conditions. In Cases 22 and 23, operated on seven and fifteen days after admission respectively, had the operation been postponed for a few weeks the apparent necessity for it would have disappeared. Dr. Cullingworth would no doubt in reply point to cases in which life was lost from the postponement of the operation, and I admit that the teaching of those who do not agree with him may lead to errors in this direction. But, looking at the proposition as framed by himself, I think that the unnecessary operations which would be done if it were generally acted on would lead to loss of life and suffering to patients greater than would come from the practice of never operating for inflammatory disease until medical treatment had been given a prolonged trial. I can therefore only adopt Dr. Cullingworth's third proposition with the alteration that surgical relief is sometimes called for, but should not be undertaken till medical treatment has been fully tried. Proposition 6 I think too sweeping. No general assertion like that can be applied to every case. Suppurating cysts out of reach by the vagina are better dealt with by the abdominal method. Mr. Doran reminded us of the recent innovation introduced by French surgeons—viz., the removal of the uterus per vaginam for pelvic suppuration. I think that removal of the uterus in such cases is an unnecessary mutilation; but the preceding preliminary to this, the "*débridement vaginal*"—that is, the division of the vagina round the cervix uteri, securing its vessels and freeing it, and then breaking open purulent collections in the broad ligament with the fingers—I think an improvement, which may sometimes obviate the necessity for abdominal section.

In conclusion, I think Dr. Cullingworth's practice will become that of the future. Just as physicians in the early days of ovariectomy, when nearly half the patients died from it, advised postponement as long as possible, but now advocate its performance as early as possible, so I have no doubt that as diagnosis becomes more accurate the cases proper for operation will become capable of better definition, and early operation will be the rule. At present the diagnosis of the cause of pelvic peritonitis is so obscure that I think if early abdominal section were the general practice in all cases of pelvic peritonitis, the mortality from the operation would be greater than that from the disease.

Harley-street, W.

1 Transactions of the Obstetrical Society, vol. xxxiii., p. 453.

HYÈRES SANATORIUM.—This institution, which has been closed for some time, has been reopened with improved arrangements and considerably increased accommodation. The sanatorium, which is intended principally for the children of the poor of Lyons who are suffering from scrofula, contains 100 beds, and in order that the children may have sea-water baths throughout the year funds have been provided for heating the water during the winter months. The children will be brought from Lyons in a specially constructed saloon carriage.

#### GREAT NORTHERN CENTRAL HOSPITAL.

COLLAPSE AFTER OVIOTOMY; TRANSFUSION; RECOVERY.

(Under the care of Dr. LEONARD REMFRY.)

THE following short account of a rare complication during the after-treatment of a case of ovariectomy is important, and there are two points to which we would draw attention. The first of these is the complication itself, and it is very probable that Dr. Remfry's idea is the correct one—namely, that the gradually developing collapse was due to a hæmorrhage. The symptoms were similar to those developed in two cases of concealed intra-peritoneal hæmorrhage from slipping of the ligature of the ovarian pedicle which were under our observation, in which the wound was opened and ligatures reapplied. In both the pedicles appeared to be quite secure at the completion of the operation. Both of them ended fatally, but it is possible that had the method and advantages of saline infusion been known and practised, a different result might have been obtained. Dr. Remfry's case illustrates the value of warm saline infusion, for it is difficult to do otherwise than describe the rapid improvement which followed its employment, to its influence on the system at large. It has been suggested that the effect of a saline infusion is more marked when a condition of collapse is due to loss of blood than when it is unattended with hæmorrhage, or the loss of blood is not a considerable factor in the case. Although our knowledge is daily increasing we still require the record of recent observations as to the result of this treatment in cases of excessive shock with tendency to a fatal collapse. A debate at one of the societies would do much to help us if the members would contribute their facts and not give opinions only.

A married woman aged twenty-eight was admitted to the Great Northern Hospital on Oct. 12th, 1892, for operation. On examination per abdomen there was a large, rounded, fluctuating tumour rising to within three inches of the ensiform cartilage, rather more prominent on the right side. In the right hypochondrium some solid masses were detected. Dulness was present over the tumour generally, comparative resonance in both flanks and distinct resonance above. Fluctuation was very marked from any part of the swelling to the anterior vaginal fornix. The uterus was behind and to the right.

Dr. Remfry performed ovariectomy, assisted by Mr. Raymond Johnson. The operation was a very simple one. There were no adhesions. The tumour, which contained a dark grumous fluid, was for the most part unilocular, but contained a few secondary cysts. The pedicle was broad and contained some unusually prominent vessels. These were first of all tied separately and then the rest of the pedicle secured in the usual way, including the first ligature. The stump was returned perfectly dry. The patient took the chloroform well and the whole operation did not occupy more than forty minutes.

All went well till 8.30 p.m.—i.e., five hours after the operation,—when the patient began to vomit and retch repeatedly and became very restless. The temperature was slightly subnormal; pulse 120. She gradually grew paler and more restless, complaining continually of pain in the left iliac fossa. At 10 p.m. the pulse was 140 and hardly to be detected at the wrist. Ether and brandy were subcutaneously injected and a little champagne given by the mouth. The collapse continued with cold extremities and perspiration. A nutrient enema containing brandy and opium was given. Later on Dr. Remfry was sent for, and on arrival at 2 A.M. found the patient in much the same condition. She was apparently moribund, with extreme pallor, cold extremities, and cold sweat. Temperature 97.8°; pulse extremely feeble and fluttering in right radial, not to be felt at all in the left.

Respiration relatively good, never becoming markedly shallow or sighing in character, and about 30 per minute. Examination per vaginam found Douglas's pouch apparently empty. Any reopening of the abdomen was of course out of the question on account of the extreme collapse. It was decided to try transfusion as the last chance. The apparatus was of the simplest, consisting as it did of a glass cannula, some indiarubber tubing, and an ordinary brass ward syringe. The fluid was ordinary salt and water (one drachm and a half to the pint) at a temperature of 110°. The right median basilic vein was opened in the usual way, and the cannula tied in. Altogether about two pints and a half were injected with numerous short intervals during the refilling of the syringe, and one long one of several minutes. After about half a pint had been used there was a distinct improvement, for the left radial pulse could be distinguished, though quite uncountable. Before the operation was completed the lips showed a faint pink colour and the extremities began to be warm, the patient voluntarily expressing herself as feeling better. The pulse was now countable, 170.

Very gradual improvement continued. At 5 A.M. there was a slight rigor, the temperature rising to 100.8°. A hot brandy and beef-tea enema was given, and as the patient was very thirsty she was allowed to sip hot water occasionally. At 8 A.M. the temperature was 99.6°, the pulse 180, stronger; the extremities were warm and the mucous membranes not anæmic. An enema containing forty grains of quinine was given, and ordinary nutrient enemata were ordered every four hours. After this the patient had some good sleep, and at 10.30 A.M. the temperature was normal and the pulse 137. During the day all went well, and in the evening the temperature was normal and the pulse 105. Some champagne and milk and soda by the mouth were retained. After an excellent night's rest the patient next morning was in good spirits, complained of no pain in the abdomen, had a normal temperature, and a good pulse of 100. Eleven days after the operation she was practically well; the abdominal wound was well healed, and there were no abnormal symptoms of any kind.

*Remarks by Dr. REMFRY.*—The case is a highly interesting one—first, because of the extreme collapse so gradually developed; and, secondly, because of the equally gradually developed recovery and the efficacy of the transfusion. What was the cause of the collapse? It is impossible to speak with certainty. Was it hæmorrhage or was it one of those obscure disturbances of sympathetic origin? Against the theory of hæmorrhage it is impossible to bring forward any one decisive argument. The following details, however, should not be lost sight of, as collectively they are important: (1) the special care with which the pedicle was tied and its bloodless appearance before the abdomen was finally closed; (2) the steady improvement under transfusion, without the occurrence of any further, even temporary, collapse; (3) the absence of the least resistance in Douglas's pouch; (4) the almost normal respiration throughout. I may say that, beyond passing a sponge into the pelvis and feeling the left ovary with two fingers, there was no manipulation inside the abdomen. My thanks are due to my house physician, Dr. Mason, for his great assistance in the treatment adopted and also for his accurate notes of the case.

#### LANCASHIRE COUNTY ASYLUM, RAINHILL.

A CASE OF FATAL COMA OF UNEXPLAINED ORIGIN.

(Under the care of Dr. W. F. MENZIES, Senior  
Assistant Medical Officer.)

THE following case was one of ordinary lactational melancholia ending fatally by convulsions and coma. Somewhat similar instances occur now and then, and are too often, we fear, passed over as unrecognised uræmia or general paralysis. The more we know about toxæmias the more do we incline to the belief that they may be the cause not only of the acute and delirious types of functional brain disorders, but also of the slower melancholic and stuporous. The former have, in fact, been long assigned to this origin. The recital of such cases may in the future throw some light upon the pathology of coma. In the series of sixty-four deaths from coma, out of 1000 investigated by Dr. Wynn Westcott, as coroner, in a London district, the cause for it was described as due either to excess of serum in the brain or effusion of blood; in a few cases congestion of the brain was alone detected at the post-mortem examination.

A married woman aged thirty-four was admitted into Rainhill Asylum on Dec. 3rd, 1891. She was emotional, excitable and hot-tempered as a girl, but always abstemious and of steady, regular habits. She had had no fevers, rheumatism, dropsy or fits; no infantile convulsions. The patient had been married eleven years; her five children were all alive and healthy, their ages ranging from ten years to twenty months. She had had no miscarriage. The husband said he had syphilis five years before marriage, but had been thoroughly treated. His doctor told him the cure was complete, and he might marry with impunity. He showed no traces of the disease. For two years he had been out of work, and nine months ago the landlord sold the furniture for rent. This seemed to have preyed upon his wife's mind so much that, after growing gradually more depressed for four months, she showed signs of suicidal propensity, and was removed to the workhouse hospital. Up to this date she had been nursing her youngest child. Afterwards she improved in health and was allowed to go home, but five weeks before admission she was found by the police wandering aimlessly about the streets at night. She then complained of great headache and dimness of vision, saying she felt as if her "brain was being twisted round," and was in terror of harming her children if left alone with them.

On admission the patient was a well-nourished woman, but flabby and toneless, with muddy, greasy skin and dark complexion. Pupils 5.5 mm., equal, of regular outline and normal reaction. Tongue clean, moist, steady on protrusion. Forehead drawn up into deep horizontal furrows. No facial tremors. She complained of an unpleasant taste in her mouth; other special senses normal. No impairment of general sensory or motor nerves; optic discs and retinae normal. Heart not hypertrophied; other thoracic and abdominal organs normal. Urine: 1770 cc. in twenty-four hours; sp. gr. 1016, reaction faintly acid; no trace of albumen, bile, blood or sugar. Urea: 28.34 grammes. The mental condition was one of semi-stupor, with a good deal of general depression; recent memory much impaired; attention deficient; could be roused easily to answer ordinary questions rationally; when left alone sat motionless, with hands folded and eyes cast down; was not resistive; she said that she felt as if there were "race horses rushing round" inside her head. The patient's condition remained unchanged for nine days. Temperature normal; the stupor deepened, and habits became wet and dirty; was always thirsty, and would if permitted drink a large bedroom ewerful of water at one draught. Sixteen days after admission she was seized with a convulsion, which commenced with a cry, and at once involved the left face and hand; the head and eyes deviated to the left; the pupils were equal, 6.5 mm., and inactive to light; when the fit passed off slight general rigidity remained. Next day another convulsion occurred, this time general; throughout the day slight twitchings were visible, and the mental state was coma of the usual type; the pupils remained equal, 7.5 mm.; the right reacted slightly, the left was inactive; retinal veins engorged and tortuous; some urine drawn by catheter was normal; from this time there was gradual failure of respiration, the lungs becoming cedematous; peptones were administered through the nose-tube, as she was unable to swallow. She died five days after the first convulsion.

*Post-mortem examination.*—The notes need only a brief summary, as they throw little light upon the case. Except for slight pallor and increase of subarachnoid fluid the brain appeared normal. There was no thickening of membranes, which stripped with normal difficulty; no opacity; no pink patches of congestion over surface of cortex; depth, colour and striation of the grey matter were normal. Ependyma of ventricles normal. No disease of larger arteries. No softening anywhere. Pons, medulla and cerebellum normal. Fresh sections of frontal, parietal, central and occipital cortex revealed some excess of pigment and granular degeneration of the deeper layers. There were patches of broncho-pneumonia scattered about the cedematous lungs. The kidneys were healthy, no loss of depth in cortex, no adhesion of capsule. All other organs normal.

**SALE OF PUTRID FOOD.**—On the 17th inst. the secretary of the London and Provincial Coöperative Supply (Limited), Edgware-road, was summoned before Mr. Hannay, at the instigation of the Marylebone Vestry, for exposing rabbits for sale which the presiding magistrate described as being absolutely green. Evidence being given showing that the sellers were cognisant of the condition of the food, the defendant was fined £20 and costs.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

*Hepatic Abscess bursting into Peritoneum treated by Incision and Flushing.—Radical Treatment of Severe Talipes Equinovarus in Children.*

An ordinary meeting of this Society was held on Nov. 22nd, the President, Sir Andrew Clark, in the chair.

Mr. HULKE gave the details of a case of Hepatic Abscess which burst into the Peritoneal Sac and which was treated by Incision and Flushing. The patient was a man aged thirty-five, who was under the care of Dr. J. L. Paul and himself. He presented a large liver abscess which three months previously had emptied through the lung and had burst later into the peritoneal sac—an accident marked by extreme collapse. On the second day after this event the peritoneal sac was opened, a very large quantity of pus evacuated, and the sac flushed out. After this the patient's desperate condition rapidly improved and he recovered, so that for several months he was able to resume his occupation. His recovery was, however, still incomplete, an abscess having again collected and been opened in July last. The case was offered to the notice of the Royal Medical and Chirurgical Society as an encouragement to the practice of promptly opening the peritoneal sac and flushing it out under like circumstances of the escape into it of the contents of an abscess.—Dr. GEORGE HARLEY said that this was the first case recorded, so far as he knew, of recovery after flushing the peritoneal sac for removal of pus due to rupture of a liver abscess. It was rare for such abscesses to burst into the peritoneum. Though usually deeply seated they worked outwards towards the liver convexity and burst there, refilling again and again, and usually rupturing into the pleura. He thought it would be better for the patient if they ruptured into the intestine, and probably many did burst in this direction, but they escaped recognition. He referred to a case of hepatic abscess of eleven years' duration which had burst six times—five times through the lung and once through the intestine. If they refilled, this occurred rapidly, giving rise to acute symptoms. Opening these abscesses, washing them out and draining them were no guarantees against refilling.—Mr. GODFREY said that a great extent of dulness upwards did not of necessity mean that the pus was in the pleura, and he referred to a case in which a hydatid of the liver was accompanied by dulness as high as the third rib, and it was treated as an empyema. In another case in which he made an incision through the lower ribs he found on introducing his finger that the abscess was subphrenic. If patients with these subphrenic abscesses lay on the left side the dulness was usually less than when standing up; it did not simply shift as in empyema. Rupture into the peritoneum was one of the rarest accidents to happen to these abscesses.—Mr. BARKER asked what was the temperature of the fluid used in washing out the abdomen. He had often noticed that flushing of the peritoneum was followed by an improvement in the patient's condition, but after a time, if the flushing was continued, this was succeeded by depression. He himself commonly used water at a temperature of about 108° F. Latterly he had used simply boiled, sterilised water, and he thought the results were better than when water mixed with germicides was used, as the latter imported a new element into the case. One advantage of the hot fluid was that it rapidly checked oozing. The two last cases in which he had employed flushing were those of children of tender age; in one two pints of pus and in one one pint were evacuated; they were not tubercular cases.—The PRESIDENT adverted to one case of abscess of the liver which had come under his notice in the London Hospital four years ago. There was a history of dysentery six months previously, after which the patient had never been well. On admission the signs were indefinite: there were loss of flesh and colour, a temperature of 100° F., a rather rapid pulse and morning sweats. The liver was rather smaller than normal and there was no point of tenderness over it or at the shoulder. Later a little friction developed at the lower part of the back. With a long and moderately small trocar inserted from the side he withdrew about twelve ounces of pus and the patient got better. Six weeks later he was again ill with rigors and sweats, elevation of temperature, rapid pulse and discomfort over the liver, which was not

enlarged. A surgeon who saw the case used a short trocar inserted from the front, and he found no pus. The patient died and a small abscess was found in the thick part of the right lobe of the liver.—Mr. HULKE, in reply, said that in the case related in the paper the pus had already burst through the pleura. He used the water so hot that he could just bear his hand in it. Though distilled water was good, some endosmosis of water into the surface cells of the peritoneum might occur, and a neutral saline solution was, perhaps, better for this reason.

Mr. EDMUND OWEN then read a paper on the Radical Treatment of severe Talipes Equino-varus in Children. He said that the orthodox treatment of severe club-foot by subcutaneous division of the tibial tendons and of the plantar fascia, and subsequently of the tendon of Achilles, left much to be desired. The tendon of Achilles should, in all cases of congenital talipes, be the first to be divided. In not a few cases of slight equino-varus its subcutaneous section sufficed in the way of actual operation, and in severe cases the amount of the inversion of the sole could be correctly estimated only after its section. Though subcutaneous surgery in general had doubtless played a useful part, it was at the present day more or less of an anachronism. It had been entirely superseded in the operative treatment of reducible inguinal hernia, and greatly to the advantage of ruptured persons; but subcutaneous operations were still generally performed for the cure of congenital club-foot. Operating thus, comparatively in anatomical darkness, the surgeon could not know for certain what structures he was dividing, nor could he be sure of severing certain important bands, deeply placed in the sole perhaps, which chiefly prevented his obtaining the perfect and easy rectification of the foot. Moreover, in a severe case of congenital club-foot, the skin itself offered a most serious impediment to a correction of the deformity. The operation recommended in this paper for adoption in severe cases of club-foot was that introduced by Dr. A. M. Phelps of New York. It consisted in dividing every resisting structure which was encountered in a free vertical incision passing from the dorsum of the foot into the depths of the sole over the head of the astragalus, the tendon of Achilles having been first cut. The improved position of the foot was thus obtained by lengthening the inner border of the foot rather than by shortening the external border, as was usually accomplished in tarsectomy. It consisted in inserting a broad wedge of space into the astragaloscaphoid joint. This space was duly filled up with granulation tissue, which was eventually converted into a strong and trustworthy cicatricial band between the anterior and posterior segments of the foot. The treatment of the foot subsequently to the operation was simple and satisfactory, and relapse was far less likely to occur than after the old method of operating. Mr. Owen had for several years been carrying out this open method of treatment, and in a considerable number of severe cases of congenital talipes he expressed himself as highly pleased with it. Further, Dr. Phelps wrote to him to the effect that he (Dr. Phelps) had now carried it out in 200 cases with no fatal result, and with but a very small proportion of relapses.—Mr. ADAMS regarded the advocacy of the open method as a retrograde step. He himself still held to the method by subcutaneous puncture, which excluded the air and kept the wound free from after-inflammation. He thought there should be no difficulty in finding and dividing the various tendons and ligaments. He preferred to divide the Achilles tendon last.—Mr. BRODHURST agreed in the main with Mr. Adams, and said that after operating by the subcutaneous method he had never seen a relapse. He held that the skin did not interfere with the reduction of the deformity, and said he had never seen a case in which the bones were so deformed as to interfere with reduction.—Mr. HULKE pointed out that the subcutaneous method was a strictly antiseptic one, and therefore Mr. Adams' views were not so opposed to Mr. Owen's as might at first sight appear. Every surgeon in hospital practice must have seen cases of inveterate deformity in patients of a certain age in which some operation of the kind advocated on the bony framework of the foot was absolutely necessary to fit the parts for functional use. Hueter of Greifswald had proposed division of the neck of the astragalus, and Macewen and others had advocated operations on the bones. So long as these extreme instances of deformity were to be met with, so long must some method more radical than division of the tendons be adopted for treatment of them.—Mr. OWEN, in reply, said that of course this operation had

not been proposed for ordinary cases of club-foot, but only for those in which subcutaneous surgery left so much to be desired. He maintained that the use of plaster was infinitely superior to Scarpa's shoe, and that bony deformity was common in cases of severe talipes equino-varus—a statement easily verified by the study of museum specimens.

## MEDICAL SOCIETY OF LONDON.

### *Syphilis and Nervous Disease in Children.*

An ordinary meeting of this Society was held on Nov. 21st, Mr. Goodsall, Vice-President, in the chair.

Dr. W. B. HADDEN read a paper on the Bearings of Syphilis in respect of the Production of Nervous Diseases in Children. After alluding to the observations of Dr. Barlow and Dr. Judson Bury, "that nearly every variety of nervous affection of acquired syphilis has its parallel among congenital examples," as in part true, he passed on to consider the question whether syphilis was an important agent in the etiology of such infantile disorders as hemiplegia, posterior basal meningitis and sclerosis of the convolutions. In the absence of post-mortem proof, clinical evidence, however strong, must be received with reserve. He referred to Osler's work on the cerebral palsies of young children, and remarked that only one case out of 120 was ascribed to congenital syphilis, whereas Abercrombie mentioned four, if not six, out of a series of fifty.<sup>1</sup> Sachs and Petersen found two such cases out of a series of eighty-three. He reviewed other statistics of the same kind, and pointed out that the balance of opinion was in favour of syphilis being an important and a frequent cause. There were not many observations bearing on the condition of the vessels in congenital syphilis, but he thought arterial disease was probably less uncommon than was generally supposed. He pointed out that the majority of cases of hemiplegia in young children arose without any apparent cause; that syphilis was known to predispose to arterial changes in adults and occasionally also in children, and he insisted that a syphilitic history should be most carefully sought for. His own experience in this respect was based on the notes of forty cases, mostly at the Hospital for Sick Children, Great Ormond-street. Though he had no pathological experience to offer, his cases possessed a special value on account of their having been observed in very early life. He divided his cases into (1) those with an acute onset and (2) those without a definite onset. Many of the latter were probably congenital and dependent on mechanical conditions during pregnancy or delivery favouring intra-cranial hæmorrhage; others were probably associated with sclerosis of the convolutions. Many of the acute cases followed so closely on certain specific diseases—measles, diphtheria &c.—that a causal connexion might be reasonably assumed. In most, however, there was no apparent cause, the hemiplegia supervening on convulsions in children in apparent health. The commonest cause being thrombosis or hæmorrhage, the question resolved itself into the inquiry as to the causation of arterial degeneration. Up to three years of age embolism was rare, but after that it became comparatively frequent. In the cases of hemiplegia under consideration embolism might be practically excluded. With reference to syphilis he said that in twenty-five cases of hemiplegia having an acute onset no inquiry was made in three, there was no evidence in nine, in five there was a bare suspicion, in six there was a stronger history, and in two the presence of syphilis was undoubted. In discussing his cases he commented on the fact that in more than one the symptoms had supervened in children presumably syphilitic during a course of mercury, a fact which might be adduced as an argument against the specific origin of the lesions. He concluded by suggesting the following points for discussion:—1. Was there fair clinical evidence that infantile hemiplegia was often syphilitic? 2. Was arterial degeneration common in children, and what share had syphilis in its causation? 3. What share had syphilis in the causation of non-congenital idiocy? 4. Did syphilis act as a factor in the production of sclerosis of the convolutions in chronic meningitis? 5. Was mercury a constant and infallible therapeutic test in infantile syphilis? Dr. ALTHAUS, after referring to the value of the triad of symptoms—the notched teeth, keratitis and median otitis—in the diagnosis of congenital syphilis, made some

<sup>1</sup> Brit. Med. Jour., June 18th, 1887.

required on the differentiation of this variety from the acquired disease in children. Although the hemiplegia might occur in children in apparent good health, a prolonged watching would rarely fail to be rewarded with the discovery of signs of syphilis. He agreed that mercury alone was often disappointing, but combined with iodide of potassium it gave exceedingly satisfactory results in these cases.

Mr. SHEILD remarked that the deafness in children was usually not due to otitis media, but a large majority of them had complete nerve deafness caused by an effusion into the tissues of the labyrinth and auditory nerve.

Dr. LEES said that, looking to the difficulty of proving the presence of syphilis, that affection might act more largely as a cause than could be actually demonstrated; yet, notwithstanding this, he did not believe that it was to a great extent provocative of infantile hemiplegia or of posterior basal meningitis; the latter might coexist with syphilis without being actually due to it, and he related a case in which he believed that this relation existed between the two. The fact that many of these cases did better on mercury and iodide of potassium than on any other combination of drugs did not prove that they were necessarily due to syphilis. He related two cases of gummata on the cranial nerves in children, one being in a little boy and the other in a girl aged thirteen. He referred to a third case in a boy aged eight, who had a paralytic affection of the lower limbs, and who at first was thought to have spinal caries, but the case ultimately turned out to be one of syphilitic cerebral fibrosis.

Dr. BARLOW said that he could recall about six cases of hemiplegia in congenital syphilis, in two of which necropsies were made. In one, a girl aged nine, who had been under observation for five years, there were all the signs of inherited syphilis; she had a convulsion, followed later by the development of hemiplegia, first on one side and then on the other, and she later passed into a state of hebetude. There was found extensive and typical syphilitic disease of all the arteries of the circle of Willis, with marked sclerosis of both hemispheres. He said that the rule was to get generalisation of the disease all over the nervous system—first convulsions, local or general, then hemiplegia, perhaps spasm on one side and palsy on the other, then choroiditis, interstitial keratitis, and finally idiocy. Such was the typical course of cerebro-spinal syphilis. The prognosis was always bad, though the symptoms might be relieved by iodide of potassium and mercury. The true basis of observation was morbid anatomy, and it should be remembered that every kind of lesion found in acquired syphilis was found also in the congenital affection, though the distribution was different.

Dr. WALTER CARR said he had made necropsies in six cases of posterior basal meningitis and in none of them was there evidence of congenital syphilis. He considered that the remarkable definiteness of the clinical symptoms and of the pathological lesions of that disease pointed to some definite but at present unknown etiology.

Dr. WHEATON thought that some of Dr. Hadden's cases might be instances of insular sclerosis, either syphilitic or not. He remarked on the prevalence of gummata in children, which were not generally recognised. He thought that one of the commonest lesions in children was an osteitis or necrosis of the bones of the skull. In some cases of hemiplegia with Jacksonian convulsions tubercle was found in the substance of the brain.

Dr. HADDEN, in a brief reply, admitted the necessity of further post-mortem evidence, and said that his experience of the presence of gummata was very limited.

## Reviews and Notices of Books.

*Vegetable Parasitical Diseases of the Skin.* By Dr. D. C. DANIELSSEN. London: Sampson Low, Marston and Co. Bergen: C. Floor. 1892.

THIS is an atlas in large folio consisting of nine plates and seven woodcuts of the vegetable parasitical diseases of the skin, the text of which is written in Norwegian and English in parallel columns. Although complete in itself as far as the limited subject of which it treats is concerned, it really forms the fourth and fifth parts of the atlas of diseases of the skin

commenced, by the author in conjunction with the late W. Boeck, many years ago; accordingly, the first plate of the present fasciculus is numbered Plate XIV. The plates of the previous parts represented Norwegian scabies of the palm and sole, psoriasis of the back, herpes ophthalmicus, of tertiary syphilis (five plates) and anaesthetic leprosy (five plates), and the text was in Norwegian and French. The present instalment, which we hope will not be the last, is welcome evidence that Dr. Danielssen's interest in the subject of diseases of the skin is unabated.

The plates in the present fasciculus comprise favus of the body with tinea tonsurans; favus of the limbs; favus of the scalp, with artificially inoculated favus of the arm in a herpetic form; tinea, or, as the author calls it, herpes tonsurans of the head and artificially inoculated tinea on the forearm; sycosis; pityriasis versicolor; very extensive tinea circinata of the whole trunk in complicated patterns, which he considers to be the same as the herpes tonsurans maculosus of Hebra. This latter is now generally acknowledged to be the pityriasis rosea of Gibert, while this plate apparently represents a true tinea circinata in concentric circles and of wide extent. The next is a plate of eczema impetiginosum traced to the staphylococcus pyogenes aureus and albus; and, finally, there is a plate comprising the microscopic appearances of the organisms previously treated of. The plates themselves, which have been executed at Bergen, are very fine specimens of chromo-lithography, and show well the advances that have been made in that process, since the first fasciculi were printed by the same firm some thirty years ago.

The explanatory letterpress is comprised in eighty pages, and is no mere perfunctory explanation of the plates, but contains a large amount of original matter recording experiments in inoculation of the various organisms. Among other results of Dr. Danielssen's observations, those on favus inoculation (which primarily produced vesicles, the characteristic favus crusts appearing later) are specially worth quoting, as he comes to the conclusion that they point to there being only one kind of favus fungus, in opposition to the cultivation experiments and deductions of Quincke, Elsenberg, Frank, Unna and others which he quotes. The text, indeed, is very interesting and well worth reading, though, like the bibliophile with the *édition de luxe* depicted by Du Maurier, owing to the enormous size of the pages, it is somewhat difficult to decide how to hold it for perusal. It is, however, well worth the extra trouble, and we can heartily congratulate both author and publisher on this handsome contribution to the knowledge of vegetable parasitical diseases.

*Disease in Children.* By JAMES CARMICHAEL, M.D., F.R.C.P. Edin. Edinburgh and London: Young J. Pentland. 1892.

THIS is the latest addition to the series of Pentland's "Students' Manuals." It will be observed that Dr. Carmichael prefers to call his work "*Disease in Children*" rather than "*Diseases of Children*," since he holds that, "with few exceptions, and those mainly of a congenital nature (malformations), we are dealing with the same diseases as in adult life, modified as they are by the conditions of growth and development going on in the child. It is not strictly correct to talk of diseases of children as we would of women, who suffer from ailments peculiarly their own. Disease in children must be studied on the same lines and by the same methods as disease in adults." This seems to us a just and necessary distinction. The chief difficulty in the way of a writer of a manual on the subject lies in the reception and rejection of material. He feels justified in assuming that the reader already possesses a fair acquaintance with some of the ordinary works on practice of medicine, and aims rather at emphasising those clinical features and therapeutic

problems which present themselves in the case of children. Hence many works on the subject touch very lightly on pathology, are incomplete regarding clinical details and can only be profitably studied by the student when he has been well grounded in the theory and practice of medicine. We have examined Dr. Carmichael's volume with care, and, as a work which, as he says, is "limited in extent and of a purely clinical character," we regard it as a very satisfactory performance. It would be difficult within the compass of rather less than 600 pages to give a more comprehensive, and yet succinct and practical, survey of the subject than that afforded by the author. The arrangement of the work is good, the information is accurate and well up to date, and the style is forcible and lucid. The diseases to which children are specially prone, such as pertussis, rickets, catarrhal pneumonia, rheumatism, chorea, pseudo-hyper-trophic paralysis &c.; receive adequate attention. The subject of treatment is considered very fully and the advice given is practical and judicious. No doubt, in a department such as this, where so many questions remain *sub judice*, exception might be taken to some of the author's recommendations. Thus, to take only one example, Dr. Carmichael seems to put considerable faith in diuretics for the cure of ascites—a sufficiently common but nevertheless probably erroneous view. He also recommends purgatives for this condition, whereas there is a growing opinion among the best authorities that they are usually injurious. We wonder what evidence Dr. Carmichael has for his assertion that "the so-called idiopathic ascites is common in children." We question this assertion very seriously. Still, we repeat, the author's views on treatment are in general sound and valuable. The writer is felicitous in some of his brief and pithy statements of knotty problems. It would be difficult to convey better in a single sentence what is known regarding the pathology of rheumatism than the following:—"The rheumatic diathesis "indicates a liability under certain predisposing causes—such as exposure to cold and damp, associated with disorder of secondary digestion—to the evolution of definite morbid processes in the blood and sero-fibrous tissues which is termed rheumatism, the intimate pathology of which is still *sub judice*." The chapters on Nervous Diseases are full and comprehensive and include a good account of Friedreich's ataxia. The author devotes an appendix to the questions of food and medicines in general, and the modes of preparation of special articles of diet for the sick and the idiosyncrasies of children with regard to drugs are fully considered. The clear printing, freedom from printer's errors, good paper and tasteful binding of this volume are very creditable to the publisher.

#### OUR LIBRARY TABLE.

*Guy's Hospital Reports, 1891.* Edited by N. DAVIES-COLLEBY, M.A., M.C., and W. HALE WHITE, M.D. Vol. XLVIII., being Vol. XXXIII. of the third series.—The first impulse of the member of the profession into whose hands this volume comes will be to search for the statistical report of the hospital. They will be anxious to know what cases, and in what number and variety, have been under treatment in the various departments of the hospital, and with what result. The feeling of disappointment at finding absolutely no "report" which can be called a *report* of the hospital will not be quite compensated for by the papers on various subjects by members of the staff, lecturers &c., however excellent, or by the list of specimens added to the pathological museum during the previous year, which is included in the volume. The contents of the volume include a paper by Dr. Hale White, on the Treatment of Chlorosis by Hydrochloric Acid, in which he comes to the conclusion that it will not cause more improvement than would be produced by rest

in bed with good food. Dr. H. J. Campbell writes on some of the interesting pathological conditions met with in animals from the post-mortem room of the Zoological Gardens. He has also an interesting contribution on the Localisation of Phthisis to the Apex of the Lung, and accounts for the fact of its commencing so frequently in that situation by its being extra-thoracic, and therefore placed under unfavourable surroundings as compared with other parts of the organ. Dr. Silk contributes a paper on the True Lines of Advance in Anesthetics. Dr. Beaven Rake, whose researches on the subject are well known, writes on some points in the Morbid Anatomy of Leprosy, as exemplified in the post-mortem examination of 109 cases under his care at the Leper Hospital, Trinidad. Dr. R. A. Bird gives his theory of the Origin and Spread of Variola. Dr. Frederick Taylor writes on Malignant Endocarditis, with cases; he also describes a case of Actinomycosis of the Liver and Lungs. Drs. Perry and Shaw give the results of their examination of fifty cases of Malignant Disease of the Stomach, with a short history of the cases and description of the specimens. The position occupied by the growths is illustrated in each instance by a diagram. Dr. Shaw also gives the list of preparations added to the museum during the year 1891, many of which are rare. The papers dealing with surgical subjects are few in number. Mr. Brailey contributes from the ophthalmic department a case of Pemphigus affecting the Conjunctiva; Mr. N. Davies-Colley a case of Ileo-colic Implantation followed by Resection of Portions of the Large and Small Intestine, for the Cure of Artificial Anus due to Gangrene after Strangulated Hernia. There is also a contribution by Messrs. Tubby and Manning from the physiological department, on the Properties of Pure Human Succus Entericus, with a few notes on Absorption by the Bowel and Intra-abdominal Pressure, based on the results of examination of Mr. Davies-Colley's patient. Mr. A. Parkin describes seven cases of Intra-spinal Hæmorrhage, in all of which the hæmorrhage was situated in the cervical region and was the consequence of injury. Papers are also included on the Volumetric Determination of Uric Acid in Urine, by Mr. F. Gowland Hopkins, and on a Form of Blood-pressure Manometer, by Dr. Starling and Mr. W. M. Bayliss.

*The Asclepiad.* Third Quarter, 1892. Vol. IX., No. 35.—The first paper in this interesting periodical, issued by Dr. B. W. Richardson, is the third of a series of lectures delivered twenty-two years ago on the Cause and Prevention of Death from Chloroform. This lecture deals with the modes of death and the measures of prevention of fatalities under the anæsthetic. Dr. Richardson says that death may take place in one of four ways—viz., (1) by apnoæal syncope, (2) by epileptiform syncope, (3) by cardiac paralysis, and (4) by shock. His practical hints are sound and sensible, and it may be noted that he commends the administration of alcohol prior to the administration of chloroform, if only for its moral effect upon the patient. He adds to the lecture a commentary written this year upon a few points of importance, in which he expresses a preference for Junker's inhaler. This valuable paper is followed by the text of a "maiden speech in the French tongue," delivered by him on June 6th, 1892, at a banquet given by the Société Française d'Hygiène to the Sanitary Inspectors' Association. Amongst the "Opuscula Practica" in this number are some wise remarks on the golden rule of "do unto others" in the treatment of disease. The memoir of Sir Thomas Browne, the author of the "Religio Medici," is as interesting as any of the series which add such a charm to the *Asclepiad*, especially valuable as it is in the critical analysis of the famous book. A contribution to the subject of Vital Cohesion and a discussion of the Opium Question are amongst the remaining important articles of the number.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 26, 1892.

EVEN a hasty glance at our report of the proceedings of the General Medical Council will show that its attention has been occupied by a variety of subjects of more or less interest to the profession and the public. The address of the President is generally a good guide to the main subjects of interest to be discussed in the course of the session. It was so in the case of Sir RICHARD QUAIN'S address on this occasion. Perhaps the subject to which he devoted most attention in his remarks was that of the illiberal legislation of foreign countries, notably that of France and Switzerland, in prohibiting the practice of medicine by foreigners, including Englishmen, in these countries, even when such practice is confined to cases of patients of their own nationality. It is sad to think that these restrictions, especially in Switzerland, are kept up mainly at the instance of the medical profession. Apart from this professional feeling, it is understood that the Federal Government would be willing to conclude with England an arrangement of reciprocity.

Sir RICHARD QUAIN spoke with feeling on this subject, and indicated that, in view of such jealous and narrow laws, English physicians should reconsider their practice of sending patients to great distances and inaccessible places, where most of all they may need the "special care of their best friends, English physicians," and where it is hard indeed if they cannot at least have medical attendants of their own nationality. We cannot believe that the republics of France and Switzerland will always display such want of liberality to the English profession, which has done so much to make the sanitary reputation of French and Swiss health resorts. After Sir RICHARD QUAIN'S address the Council proceeded with the details of its business. In connexion with the table showing the results of competition for commissions in the Medical Staff of the Army, the Director-General had informed the Registrar, in accordance with a request of the Medical Council, of four instances in which candidates were found to be deficient in the matter of correct spelling. The Council hopes, by tracing such defects to the bodies responsible for the preliminary education of such students, to stimulate these bodies to more care in the future. It transpired that the bodies responsible in these four cases were in one instance the Royal University of Ireland, in one the College of Preceptors, and in two the Royal College of Surgeons in Ireland. Sir JOHN BANKS and Professor MACNAMARA, with commendable promptitude, expressed their regret that their respective bodies had been at fault and their determination to bring the facts under the notice of these institutions.

Perhaps the most novel subject which has arisen so far in the course of business is the consideration of various documents in regard to Medical Aid Associations, and especially in respect of the nature and tendency of the relations of the medical officers of such associations to the members and to the general purposes of the associations. Our readers are by this time very familiar with the contention of Dr. LESLIE

PHILLIPS that such associations are practically companies for carrying on medical practice, in which all the work falls on the medical officer and most of the profit accrues to the association; and that neither the interest of the public nor the dignity of the profession is served by medical men who accept the appointments. A huge petition signed by over 1000 practitioners showed that Dr. PHILLIPS is not alone in his contention, which, however, is flatly contradicted by the managers of the associations, who have made counter-statements to the Council. The Council exercised an admirable judgment in refusing to accept hastily any representations on the subject. They have appointed the following members as a committee—viz., Dr. GLOVER (chairman), Mr. WHEELHOUSE, Mr. TEALE, Dr. LEECH, Dr. BRUCE, and Dr. MACALISTER. The whole subject is to be referred to them. They are authorised to take evidence and, after fully sifting the matter, to report at the next session of the Council. The Council was liberal enough even to sanction in a negative sort of way the expenditure of £100 for shorthand writing and other unavoidable expenses, but added, with characteristic caution with regard to expenditure for any but its own immediate and routine purposes, that no more was to be incurred without the previous sanction of the Finance Committee. Sir WALTER FOSTER and Dr. GLOVER argued that the funds provided by the profession could not be better spent than in investigating a subject deeply affecting its interests and its honour, but they did not succeed in getting a larger grant. Doubtless, however, if there be any prospect of bringing about improved relations between the profession and the industrial classes in such a vital matter as their medical attendance on honourable terms, the Council or its Finance Committee will not hesitate to show its sympathy by some small increase of the sum. It is creditable to both sides that they seem anxious, without any question of payment, to give all the information in their power to the Council.

The Council did still more work on Tuesday. It resolved to apply the doctrine of the offence of "covering" to those on the Dental Register, as it has long done to those on the Medical Register. It is pretty clear that there is much need for this step and that much dental business is done by unqualified assistants, to the injury of the public and of honest dental practitioners. An important question was raised in the form of an amendment on the Standing Orders, recommended by the Executive Committee, and of which we shall probably hear more. The Council, as is well known, often restores names which, for sufficient reasons, it has seen fit to erase from the Registers. It has transpired lately that in some instances the bodies, from which the qualifications of the practitioners whose names have been so erased were derived, have absolutely withdrawn the qualifications, and that by their laws or charters they are unable to restore them without a fresh examination. This does not apply to all the bodies.

It might so happen that, in the case of a practitioner who originally possessed but one qualification which had been absolutely withdrawn by the body granting it, the Medical Council might order his name to be restored while he was entirely without the only qualification on the strength of which he was originally registered. This is a very awkward state of matters. The change in the Standing Orders will

tend to prevent haste in the action of the bodies; but some way should be found for harmonising such action with the action of the Medical Council, otherwise a practitioner, whose offence would be sufficiently met by his temporary removal, may be finally removed from the profession.

On Wednesday the Council had several painful cases to deal with under the disciplinary clauses of the Acts, particulars of which will be seen in our reports. We do not care to rejudge such cases, or to call in question the discretion of the Council; but we venture to say that none will accuse it of too much severity in any of the instances.

“SERIOUSLY, the safe side for the lay world to take is that which is against the vivisector. We shall not be absurd enough to say that no knowledge of value can be gained by such experiments.” These words, used by one who is writing against “vivisection,” appear to express also the sentiments of some of those outside the lay world who nevertheless wish to make for themselves friends therein. The anti-vivisection controversy has now passed beyond the initial stage, and the views that men hold and the parts they play have been made abundantly manifest in their various expositions and exhortations. This lay agitation has been carried on mainly in the columns of *The Times*, where have been set forth, in language the meaning of which could not possibly be misunderstood by the most obtuse of intellects, the arguments for and against experiments on animals. In the first instance, those who advocate experiments on animals were supposed to be on their defence, but as the discussion advanced it soon became evident that the “anti-vivisectionists” had put themselves in a false position through following the lead of those who were either remarkably careless or deplorably ignorant.

The position taken up by some of the “anti-vivisectionists” is that under no circumstances is experimentation on animals justifiable; but we venture to think that this position is not now generally accepted as being tenable. It is daily becoming more and more evident that the question to be determined is—how much good has been done, and how much information has been obtained, by experiments on living animals. Of course, even “anti-vivisectionists” disagree on this matter, but to Mr. LAWSON TAIT’s credit must be placed the fact that he has accepted this as being the real point at issue. He maintains that no great advance in medicine or surgery has been made which could not have been gained by clinical observation. It is quite conceivable that there may be a grain of truth in this statement, but let anyone attempt to calculate the enormous loss of life and the fearful amount of suffering that would necessarily have been involved in this slower process of gaining knowledge, and then let him put the question to himself whether it is not better that the lives of a number of the lower animals should be sacrificed, with the suffering in their case reduced to a minimum, than that a holocaust of human sufferers should be rendered necessary.

In this matter we ought to have advanced beyond the stage of mere recrimination, and even those who have spoken most strongly in favour of the total prohibition of experiments on animals are now in a sufficiently calm state of mind to go into it thoroughly and with as little bias as possible. The questions to be discussed are: 1. Are experiments on animals justified by the results obtained? 2. Are such

experiments carried on under proper restrictions and by qualified and humane investigators in this country? To both these questions we can answer unhesitatingly in the affirmative. If, however, Mr. TAIT’s utterances are left unanswered the public might be allowed to remain under the misapprehension that those who advocate experiments on animals have put themselves beyond the pale of ordinary argument, and that it is a matter of supererogation at this period to affirm that experiments on animals are of the slightest use. In a letter to *The Times*, in answer to an article that appeared in the columns of that journal, Mr. TAIT, for example, sets forth several definite propositions to show that experiments upon animals are useless in enabling us to determine how the human organism will react. He, however, is extremely unfortunate in his examples. If no advances had been made as regards our knowledge of the circulation of the blood between the time of GALEN and that of CÆSALPINUS or SERVETUS, and if HARVEY by employing experimentation was able to set this question at rest, even allowing that he was not the discoverer of the circulation of the blood, and since he could not argue it out as Mr. TAIT would have done on the material offered by GALEN, was it not well that the period between that in which HARVEY carried on his experiments and obtained his results, and that when it could have been reasoned out by Mr. TAIT, should have been utilised in the study of more advanced problems of disease in connexion with the circulatory apparatus? Then, too, as regards the improvements made by JOHN HUNTER in the ligation of arteries in cases of aneurysm, most authorities will feel inclined to accept JOHN HUNTER’s statement, or rather the statement of Sir EVERARD HOME, his brother-in-law, as to the process of reasoning by which he was led to his method of treatment, in preference to any interpretation of his methods and arguments offered at this time of day by any critics, however able. In this matter it appears to us that JOHN HUNTER’s latter-day apologist has not been perfectly ingenuous, for Dr. HAYCRAFT has on more than one occasion supplied him in open meeting with chapter and verse (of which he has since made but scant use) from the works of JOHN HUNTER, proving that that writer was guided to his successful results through experiments on animals. The paragraph quoted by Dr. HAYCRAFT runs as follows: “The results of these experiments confirmed Mr. HUNTER in his opinion that the artery, in cases of aneurysm, is in a diseased state, and *led* [the italics are ours] him to believe that the disease often extends along the artery for some way from the sac, and that the cause of failure in the common operation arises from tying a diseased artery which is incapable of union in the time necessary for the separating of the ligation.” Could anything be more definite or more convincing?

The references to VON GRÄFFE’s work Mr. TAIT should never have made, as he confesses to his own comparative ignorance of diseases of the eye, whilst few people would have regarded him as one likely to accept a negative as evidence against a positive. Again, all who have heard Professor MACLEWEN, or who have followed the accounts of his wonderfully successful operations on the brain, will know how deeply that surgeon feels himself indebted to the researches of those experimentalists who have worked at the

subject of localisation of function in the brain, and to Sir JOSEPH LISTER for his experimental work on anti-septics. The mind and skill of Professor MACBURN might have been engaged in working out some such problems in their earlier stages had not so much of the ground been already cleared, so that his work of saving life and alleviating suffering could be directly entered on. Mr. GODLEE and Professor HORSLEY went a step further, and brain surgery to-day has become a recognised branch of the surgeon's work—a recognition it could not have obtained for years to come, and perhaps not for all time, had not experimentation on animals been resorted to. In Mr. TAIT'S own department of surgery we make bold to say that he now obtains results which could never have been compassed had not M. PASTEUR and Sir JOSEPH LISTER published their experimental researches; for, although Mr. TAIT criticises the details and methods of the antiseptic treatment, he, by his own showing and treatment, accepts the general principles worked out by these two great pioneers, and his patients recover and are not attacked by septicæmia or puerperal fever. We have now a knowledge of the conditions—by no means a perfect knowledge—under which these diseases are developed, and of the special conditions under which the etiological factors in these diseases can retain their vitality outside the body, under which they can invade the body and under which they are enabled to remain alive in the body; and whatever Mr. TAIT may think he daily avails himself of this knowledge. Anyone reading the dismal accounts of the outbreaks of hospital gangrene and of septic diseases generally recorded by Sir JAMES SIMPSON and others of the last generation of surgeons, or even of the older members of the present generation, and bearing in mind the tone of utter helplessness and hopelessness that runs through such accounts, cannot but be struck by the wonderful improvement in the statistics that are now at our disposal. Could Sir JAMES SIMPSON only come back amongst us what arguments would he not be able to adduce to help to convince us that we should look upon it as a duty to have recourse to any experiments on animals that could proffer promise of help to obtain results so different from those that surgeons in his time had to be content with.

As regards tuberculosis, it has been urged that because tuberculin has failed to give markedly satisfactory results when used in cases of tuberculosis, therefore KOCH'S experiments and investigation into the subject of tuberculosis have been of no value as regards the treatment of that disease. Could a greater mistake be made? The whole history of preventive medicine goes to show that not until the direct exciting cause of a disease had been found could any effective steps be taken to deal with the disease itself. Whatever KOCH has or has not done, he has obtained abundant evidence as to the part played by the tubercle bacillus in the etiology of tuberculosis. We have still much to learn about the saprophytic life history of this bacillus before we can attack it from every point, but we do not hesitate to say that there are already thousands of persons free from tuberculosis who would had they been born ten years earlier inevitably have been suffering from this disease. The increased precautions taken to disinfect the sputum of tuberculous patients and to avoid the use of milk from tuberculous animals may account for many of these thousands

whilst better ventilation and better general hygienic conditions, the necessity for which was emphasised by the fact that the tubercle bacillus requires favourable conditions for its development, may be held responsible for the others. The causes of disease can only be completely studied by having recourse to experiments on animals. The main part of the work must necessarily, from the nature of the medical practitioner's occupation, be done by careful observation at the bedside, as his main duty is to relieve suffering at the time he is called in; but we maintain that, although it is the duty of every man to go carefully, reverently, and hopefully to work with an open mind to learn all he can from clinical observation, he must be prepared to have recourse to experiments in order that he may be able to fill in wide gaps or to make fresh excursions from the points already won.

Mr. TAIT is a keen, we might almost say an obstinate, controversialist but an able surgeon, and we hope ere long we may hear that he has re-read his evidence and has been convinced that there is some good in "vivisection." As regards the second question, even Mr. BERDOE acknowledges that English physiology is honourably distinguished from Continental physiology, in that experiments made in English laboratories are comparatively moderate and within bounds. Even with some added qualification there breathes a reasonableness in this statement that gives promise of better things to come. Every experiment must be reported to the Home Secretary in a most detailed fashion, and these reports are published annually. Every licensed place is most carefully inspected at irregular intervals, and the animals experimented upon, if kept alive after the effects of the anæsthetic have passed off, are subjected to most careful examination to ascertain whether there is any discomfort or pain. English physiologists are Englishmen, and they help to form a public opinion that has decided in favour of experiments on animals, but against all unnecessary cruelty.

At the request of the Surbiton Improvement Commissioners the Surrey County Council deputed their medical officer of health, Dr. SEATON, to make inquiries into the health and sanitary condition of Surbiton. On Oct. 24th last Dr. SEATON submitted to the council the opinions he has arrived at as a result of his examination. It will be remembered that we appointed a Sanitary Commission to investigate the same subject, and that the report of this Commission was published in THE LANCET of July 16th of the present year. The system of intermittent pumping practised at the outfall sewage works, as a result of which it had been asserted that the air of Surbiton was at times offensive in the morning, was mentioned in our report, although our Commissioner was unable to confirm this statement during his visits. Dr. SEATON considers the present plan objectionable, chiefly because it allows sewage to stagnate for several hours in the sewers, and strongly recommends the substitution of continuous pumping at the works. He was, however, unable to detect any nuisance traceable to the present method, and was also able to satisfy himself that "the air in the sewer was travelling in the direction that might be expected, and with about the same gentle movement as in the daytime." The extremely well kept condition of the roads is also highly

commended. With the state of household sanitation Dr. SEATON'S report does not deal; but the county medical officer of health "certainly would advise the commissioners to make better arrangements for receiving and attending to any complaints that may be made about houses by medical men and householders, and to provide for the systematic inspection and registration of any lodging-houses, boarding-houses, schools" &c. Our report drew attention to several instances of insanitary houses erected since the passing of the Surbiton model by-laws in 1880, and noted the prevalence of cases of diphtheria (from the report of the medical officer of health) in numbers larger than those of any of the other acute specific diseases. This fact is also touched upon by Dr. SEATON, but not followed out further. Attention is directed to the report of THE LANCET "Special Commission on Sanitation in relation to the Law and Practice of House-letting," which appeared in our issue of August 20th last, and the importance of the matters discussed in this document is impressed upon leaseholders. In our report on the drainage of Surbiton it was pointed out that the offices of borough surveyor and inspector of nuisances were filled by the same person, a condition of affairs which Dr. SEATON thinks most undesirable, at the same time bearing testimony to the good work that has been done during the time that this arrangement has been followed. In conclusion Dr. SEATON remarks that, having given much attention to the system of voluntary registration or certification of houses, as practised at Eastbourne, he would be ready to report further upon the matter if desired by the Surbiton Commissioners. We note that the Surbiton sanitary authority will probably soon deal with some of the most important recommendations in Dr. SEATON'S report—e.g., the continuous pumping of sewage, the separation or not of the offices of borough surveyor and sanitary inspector, and the creation of the office of an expert sanitary official whose services shall be free to any resident in the district for the purposes of advice regarding household drainage and superintending alterations in drainage.

## Annotations.

"No quid nmls."

### THE DIFFUSION OF SMALL-POX.

THE diffusion of small-pox continues, although the extent of the several outbreaks is in most places not wide. In Warrington a third small-pox hospital is to be provided. It is to be hoped that it will not be near dwellings, for the two hospitals now in use have, it is to be feared, increased rather than decreased the extent of the epidemic by aerial diffusion of the infection. Since the visit of Mr. T. W. Thompson, medical inspector under the Local Government Board, a fresh impetus has been given to revaccination, and up to last week it was stated that out of some 400 attacks in Warrington no person revaccinated before having actually received the infection of small-pox had contracted the disease. Leicester, to which we refer elsewhere, has, we hope, got the disease for the moment under control; but cases of small-pox have occurred, both at Coventry and at Thame, in persons taking the infection at Leicester. In Leeds

there is risk of a serious spread of the disease, and Dr. Cameron again urges the need of notification, for small-pox remains unknown to the authorities and is confused with chicken-pox. At Liverpool forty-one cases were under isolation last week. At Otley a temporary small-pox hospital is being hurriedly provided. At Chesterfield fifteen cases are under treatment in hospital, and the disease is stated to be on the increase. A number of attacks have occurred amongst navvies engaged in different works in several parts of the kingdom, and it is evident that a careful watch should be exercised over this class of labourers, and that every effort should be made to induce them to submit to revaccination. The main difficulty of this lies in the fact that they do not like to run the risk which is involved by reason of the nature of their work and its attendant physical exertion. Moss-side has small-pox due to labourers on the Manchester Ship Canal. Manchester itself has provided special pavilions at Monsall in order to check the disease. Cases are also heard of from other localities, such as Stamford, Featherstone, Bramley, Bradford, Oldham, Sheffield, Wakefield, Huddersfield, Halifax, Chadderton, Blackburn and Newport (Mon.).

### AN OBSTRUCTIVE ADVERTISEMENT.

THOSE who are acquainted with London thoroughfares and the numberless impedimenta which beset them will not be surprised that a protest has been raised against the addition of one other obstacle to the tide of traffic. The presence of an omnibus used for advertising purposes only constitutes in the circumstances much too large a bid for public favour. Did it in any more practical way minister to public convenience objection might perhaps be silenced. Thus far it serves no other or higher purpose than that of a drifting handbill of the most massive and obstructive character. It comes as a mere lounge or street performer among the working craft of the streets. We need hardly wonder therefore if, with all its emblazonry of decoration, it is consigned to some quiet by-street, and assuredly we shall not regret to see it stranded outside the swift and swollen stream of public business.

### THE THIRSK DISASTER.

THE inquest held by the coroner for the North Riding of Yorkshire upon the victims of the accident on the North-Eastern Railway has resulted in a curious verdict, in which the jury award blame upon principles which it is not easy to understand and grounds which do not at all appear in the report of the evidence taken before them. The directors of the company are censured in strong terms for a mishap which does not seem to have been in any way due to defective system or inefficient management, but to the failure of a signalman on the one hand and of an engine-driver on the other to perform the routine duties assigned to them—failures for which no sufficient excuse, and no excuse that is even forceful, can be put forward—failures, moreover, which are both duly recorded and denounced in the very comprehensive verdict of the jury. It is impossible not to feel that this verdict would have been very different if the erring signalman had not, in all that has happened since his unfortunate lapse, behaved in a most worthy manner. That strong sympathy should be felt with such a man in such a position is both natural and right, and we for our part would gladly confess that there is no occasion to grow angry with a man who has manifested such a just appreciation of his position and whose fault, however serious its consequences, seems to have been in itself a very venial one. But when a proper desire to show mercy in one direction leads to unjust criticism in another it is necessary even for sympathisers in the sentiment to protest against its extravagance and abuse. There is much to be said in favour of an eight

hours' night for signalmen, but it is both unfair and foolish to single out the directors of a particular railway and hold them up to opprobrium as "the persons really-responsible" for a lamentable mishap merely because, in common with many other railway authorities, they have sanctioned the employment of their signalmen for longer periods of time. We trust that a more discriminating temper will prevail in the public discussion of the lessons of the Thirsk accident, for it would be regrettable indeed if, from whatever the cause, the discussion were to degenerate into a bandying of random accusations and indignant rebuttals to which heedless charges made in such circumstances inevitably tend.

#### THE IRISH LOCAL GOVERNMENT BOARD AND CHOLERA PROSPECTS.

CIRCULARS have been issued by the Local Government Board of Ireland, entitled "Precautions against Cholera," in which all sanitary authorities are urged to utilise the present winter and spring in removing from their midst those conditions which are known to be identified with the diffusion of cholera. Vigilance as to water-supplies, sewers and drains and the like receives a prominent place in the circulars. The housing of the poorer classes is next dealt with, and then come a series of precautions which it is necessary to adopt in the case of persons already suffering from cholera, and also with a view to its prevention among the population generally. Appended to the document dealing with the latter subjects is a memorandum drawn up by the Royal College of Physicians of Ireland, containing a few practical hints for the healthy and some simple remedies for the sick. A second memorandum traces the course of cholera and refers to its prospects during 1893; it also deals with the demands that have been made as to the imposition of quarantine restrictions. The experience of England is referred to in this connexion, and the Irish public are finally told that it would be useless to place reliance upon any system of quarantine, or even to trust wholly to medical inspection of vessels entering ports. Under these circumstances the Board again urge both the sanitary authorities and the public to make their preparations in advance, so that they may not find themselves at an unexpected moment face to face with cholera spreading through insanitary conditions, and this without any ready means of defence against it. The circulars are signed by the secretariat of the Board, but it is evident that the excellent and well-timed advice which they embody emanates, in the main, from Sir F. MacCabe, the medical adviser to the Board.

#### SAD DEATH OF A SURGEON AT PECKHAM.

ON the 15th inst. Mr. G. P. Wyatt, coroner for the southern division of London, held an inquiry at the George and Dragon, Peckham, respecting the death of James Andrew Murray, aged thirty-two years, a surgeon, lately residing at 49, St. Mary's-road, Peckham, who had been found dead under circumstances of a very painful nature. Mrs. Albina Murray of Cork, Ireland, identified the body as being that of her son, who was a widower. The circumstances of this sad case are as melancholy as they well could be. From the evidence it is to be gathered that Mr. Murray's mind was to some extent unhinged owing to pecuniary and domestic troubles and excessive drinking; and that, in the opinion of those who knew him, he was a source of danger to himself at least, if not to others. It was not surprising therefore that steps were taken by someone to have his mental condition professionally inquired into. The cumbrous process of the law as to the certification of insanity in individuals was made evident at this stage, in so far as there had to be a sworn affidavit and information laid before the magistrate, who thereupon ordered a medical examination. The position and action

of the relieving officer at this point became so anomalous that they called for a strong and unfavourable expression of opinion on the part of the coroner, with whom we fully concur. It is entirely wrong that it should be possible for a member of the community who has committed no overt act to be removed from his home as a lunatic by a minor lay official before any medical examination as to his mental condition has been made. A case of this sort does incalculable harm to the working of the Lunacy Acts, and accentuates the uneasiness of the public mind on the subject. No time ought to be lost in looking after a person whose mental condition renders him a source of danger to himself or to others; but the responsibility of action ought to be thrown as speedily as possible upon the shoulders of the medical authorities.

#### THE PURIFICATION OF THE THAMES.

IT is stated that steps are being taken to apply to Parliament in the coming session for an Act which shall make illegal the discharge of any sewage, purified or unpurified, into the Thames between Egham and the intakes of the London water companies. There is little doubt that sewage-contaminated water is frequently drawn from the river by the water companies, but the method of filtration, simple though it be, would appear to free it to a large extent from its objectionable organic impurities. But does mere sand filtration effect the removal of organisms? If, for example, the dejecta of a cholera patient were thrown into the river just above an intake, it is hardly conceivable that the ordinary process of filtration would render such contaminated water perfectly safe to drink. Evidence is very much wanted to clear up this point. Meanwhile the advisability of taking the course it is proposed to take will hardly be disputed, and, further, it is only reasonable to expect that the water companies should bear indirectly part of the cost of the outlay necessarily involved.

#### LEICESTER ISOLATION ARRANGEMENTS.

THE question of the provision of a new hospital for infectious diseases at Leicester is at a standstill, and we cannot but think that the refusal of the Town Council to come to any decisive conclusion is in part due to the fact that the chairman of the Sanitary Committee practically ignored, if he did not oppose, the protest of the Leicester Medical Society, who formally objected to the aggregation of small-pox cases on the site proposed, a site on which it is intended to receive other infectious fevers. Already small-pox has spread to other wards; indeed, Mr. Bremner's account to the Council of the diseases contracted by different patients in the existing hospital is such as to make us wonder how the place can be regarded as an "isolation" hospital at all. One thing is certain, and that is that the present hospital and its "quarantine" arrangements are utterly inadequate, and have failed in their professed purpose. It was admitted at the council meeting to be an ugly makeshift, a disgrace to the town, and to afford no proper means for the so-called quarantine system. This is what we always contended. But it is no reason why Leicester should remain idle. We admit that the question of site is all important, and this especially if small-pox is considered; and there is perhaps one advantage in the postponement of the question for the moment, for the delay will prevent any new attempt to deal with small-pox in the immediate future in such a way as to prevent the provision of such accommodation for the infectious fevers generally as a town like Leicester ought to possess. The existing site is already becoming surrounded by houses, building operations are likely to increase in its neighbourhood; and if it be a fact, as alleged by some members of the Council, that other and better sites are available, such alternative sites ought to be fairly considered

before a final decision is arrived at. In the meantime Leicester appears to be more free from small-pox than it was; but even its hospital seems to be associated with the mischief of spreading the disease, for one of the persons employed in the laundry, who under local teaching very naturally refused to be revaccinated, has died of small-pox. It is, however, astonishing to find that a town identified with the quarantining of persons exposed to infection—a system which, as one speaker put it, forms an "object lesson" to the country—should allow its small-pox hospital laundrymaids "to sleep in the town." If any one thing more than another shows the need for a new hospital, and for reform in the method of dealing with infection in Leicester, it is this disgraceful state of affairs. Hence we would suggest that no undue delay should occur in settling the vexed question of site for the new hospital.

#### THE OPENING OF THE NEW BRISTOL MEDICAL SCHOOL.

THE report we published last week of this function was, through an inadvertence on the part of the reporter, less complete than it should have been. In this way we undesignedly appeared to do an injustice to Dr. Swayne, whose services formed a prominent feature of the opening ceremony, and whose munificent donation should also have been mentioned. Before the principal part of the proceedings had commenced Dr. Swayne read an interesting address, in which the history of the school was traced, together with particulars of the professional career of his predecessors so far as their connexion with the Bristol school was concerned. Unfortunately, the name of Dr. Swayne was also accidentally omitted from the list of gentlemen to whom was entrusted the task of carrying out the whole of the arrangements connected with the dinner. We regret that this mistake should have occurred.

#### MUTILATION OF THE TEETH AMONGST SAVAGES.

DR. MAGITOT of Paris has published an interesting account of the mutilation of the teeth practised by various savage tribes. One variety, which is chiefly met with on the coasts of Africa and the west coast of New Guinea, consists of the breaking of a portion of the incisor by means of a knife and a piece of wood, and is performed between the ages of twenty and twenty-five. The custom of extracting the two central incisors is found in both hemispheres. According to Zerate it has been practised in Peru from time immemorial, where it is inflicted on conquered tribes as a sign of slavery. In Africa it has been observed on the Congo, among the Hottentots and the Batoxas. The mutilation by filing has for its exclusive centre the Malayan Archipelago, whence it has spread to the adjoining islands. It is a religious act, which is celebrated with great festivities at the age of puberty, but this only by the Mohammedans. The degree and character of this filing vary with the habits of the family or caste. The operation is performed by an expert, the *Tukang panggur* (filer), by means of a chisel, three bricks, two files, a small saw and a pair of cutting nippers, the instruments being rubbed with arsenic and lemon-juice before being used. It is the fashion amongst some tribes on the Senegal River to extract the upper temporary incisors in girls when quite young and to manipulate the chin, so that it is drawn forward and the lower incisors are made to protrude so as to overlap the upper lip, thus producing an artificial prognathism. In Indo-China and Japan a girl on her marriage paints her teeth with a black varnish. However, as this operation requires time and money, it is only practised by the wealthy class. Livingstone reported that among the Kafirs a child whose upper teeth erupted before the lower ones was regarded as a monster and killed. On the Upper Nile the negroes have their upper incisors extracted, in order to avoid being sold as

slaves, because of the loss of value brought about by this mutilation. Among the Esquimaux, as described by the Abbé Peritat, in some regions there exists a custom of transversely cutting off the upper incisors, the object of this being, according to local tradition, to prevent the human chin looking like that of a dog. \_\_\_\_\_

#### THE ITALIAN ELECTIONS.

THE representation of the profession in the Italian Legislature remains almost exactly as it was before the electoral struggle, which has unseated so many old deputies and reinforced Signor Giolitti's Government with so many untried men. We note with gratification that Dr. Guido Baccelli retains his seat for one of the divisions of Rome with an overwhelming majority, and that his presence in the Chamber may still be counted on in the interests of public hygiene and medical education. A severe contest in the third electoral collegio (constituency) of Milan has resulted in the defeat of the advanced Liberal candidate, Dr. Malachia de Cristoforis, a medical consultant and sanitary reformer of the most enlightened and thorough-going stamp, whose well-inspired and outspoken advocacy of improved hygienic regulations for Milan, particularly for the minimising of zymotic disease, has been felt for good by every sojourner, migratory or resident, in that great *entrepôt* of foreign travel. More than once, when commenting on the small-pox and typhoid outbreaks that have emptied the Milanese hotels and driven the tourist public to select alternative and less convenient routes, we have had to acknowledge our indebtedness for facts and suggestions to Dr. De Cristoforis. We hope his exclusion from the Italian Legislature is only temporary. The Senate, on the other hand, has had its deliberative and debating resources distinctly reinforced by the elevation of more than one medical practitioner or investigator to its membership—the most conspicuous of these being the illustrious pathologist and sanitary reformer, Dr. Tommasi-Crudeli, whose researches and conclusions on malaria mark an epoch in our knowledge of the etiology and prophylaxis of that disease.

#### THE OUTBREAK OF CHOLERA AT LUCKNOW.

WHEN cholera extends in an epidemic form over a large district of country, or when an outbreak occurs in a large and densely populated city, it is often extremely difficult, if not impossible, to trace its progress and the causes and methods of its spread; but it is different when the outbreak is on an extremely small scale and circumscribed within very narrow limits of space and time. The conditions and all the circumstances attending it must then be well known, or should be capable of being accurately traced. A cholera outbreak of this kind has recently occurred at Lucknow among the officers of the Royal Artillery of that garrison, which seems to have been of a very sudden and unexpected character. It appears that a captain of the Royal Horse Artillery and the mess-sergeant were attacked on the morning of Oct. 19th, and that both died in a few hours. A subaltern of the 2nd Field Battery developed choleraic symptoms on the evening of the same day, and he was nursed during the night by another officer, who was attacked by cholera on the following morning and died on the same day. Two other subalterns were then attacked, but in their cases the attack was not fatal, nor was it fatal in the case of the officer of the 2nd Field Battery. We infer from the reports that all probably belonged to the same mess, and the question comes, how did the cholera-cause get into the mess house on Oct. 19th, and what were the exact local conditions of the mess at the time? No mention is made of any other attacks in the cantonments, or of the prevalence of the disease among the native population at Lucknow at the time. A special inquiry has been ordered into all the circumstances attending this outbreak,

which resulted in three deaths from cholera on Oct. 19th and 20th—viz., two officers, Captains Grierson and Head, and the artillery mess-sergeant. October is late in the season, we imagine, for the prevalence of cholera at Lucknow. It is the occurrence of sporadic cases out of due season, as it were, and sudden and unexpected outbreaks of this kind, the rest of the garrison remaining healthy, at stations far removed from the endemic area, that are so difficult to fit in with any of the existing theories of the disease. Some authorities in India regard such occurrences as the earliest indications of an epidemic which is to follow much later on—in the hot and rainy seasons of the following year, for example. The inquiry will no doubt be of a searching and exhaustive character.

#### STREET REPAIRS AND STREET OBSTRUCTION.

A REAL grievance has been exposed by a correspondent who recently noticed at some length the interruption of traffic in the Strand, which for several years has been practically unceasing, in consequence of repeated alterations in the roadway. Shopkeepers complain loudly of the loss of custom thus inflicted on them, and travellers of the delay in their journeys. We must also allow that the ever-giving ratepayer has no less ground for protest when we remember with what cold zeal, what multiplication of labouring effort, and consequent expense, the ordinary British workman surrenders the muscular equivalent of his wages. Of course no one would think of interfering with needful public works of improvement, or even of crippling the deserving efforts of private enterprise; all that we would ask for is that the disturbance referred to be justified by commensurate advantages and approved by some higher than any local authority, that due notice be given of intended alterations, that the matter be so arranged that the course of general business in the district shall not be injuriously diverted, and, finally, that the work be carried through with vigour and despatch. Such annoyance as that we have here briefly described is not limited to one street or one city. It is in greater or less degree the chronic pest of many chief thoroughfares. The particular means to be used for its cure must naturally vary with diverse local conditions. Its main excuse, however, must ever depend upon its necessity, and its temporary acceptance, even as a matter of submission, upon its compatibility with common interests.

#### THE FATAL "RUN" AT RUGBY.

THE distressing circumstances attending the recent death of a boy at Rugby School while taking part in a "run" are familiar to most of our readers. Notwithstanding that no actual blame for his death can be attributed to any one associated with the poor lad, it is impossible to overcome a certain feeling of uneasiness in connexion with the sad occurrence. No recognised precaution seems to have been omitted. Medical examination on two occasions had failed to reveal any sign of constitutional weakness. The boy himself had made no complaint of being ill. He had run several times before as far as he would have run on this occasion, and with apparent ease. Published details of the post-mortem examination are unfortunately very meagre, but the evidence thus obtained went to prove merely that death was due to syncope from over-exertion. It is worthy of note that the run, though not longer than four miles was open to boys of all ages. This is a circumstance of more than trivial meaning. The pace, not the distance, in such a case constitutes the real difficulty, for, as everyone knows who has run in a paper-chase, the "hares" who lead it are chosen for their swiftness. A young boy, if ambitious to run well, as this boy was, does not use much care in regulating his own exertion. It is very doubtful that even if he felt unequal to the task he would care to acknowledge his unfitness. He would usually be only too

ready to accept his present conditions, and to run when required to do so. Clearly, then, these must be regulated for him. To a large extent they are so regulated. No boy may run if declared physically unfit. Doubtful cases are submitted to the medical officer of the school. Little more may seem to be needful, but that little should not, in view of the recent accident, be disregarded. We would suggest that the positive test of a preliminary physical examination be required to qualify for these runs, and, further, that as a rule boys of a similar age be selected to compete together. The full advantage sought in this form of exercise, and rightly if it be well administered, would thus be obtained with a minimum of risk to those engaged in it, and the temptation to perilous and fruitless excess would be avoided.

#### THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of the Association of Fellows of the Royal College of Surgeons of England was held at 5 P.M. on Wednesday, Nov. 9th, at the residence of Mr. George Pollock, President of the Association. There was a very full attendance of members of the committee. The meeting had been called for the purpose of considering a reply to the last letter of the committee received from an official of the College, with reference to the points at issue between himself and the committee of the Association. A long discussion ensued with regard to the action to be taken, and, after various resolutions and modes of procedure had been suggested, it was ultimately agreed to appoint a subcommittee to draft a report in the form of a reply. It was agreed that the subcommittee should meet on the 14th and submit its report to the adjourned meeting of the committee to be held on the 16th, at 5.30 P.M. The committee then adjourned and met again at Mr. Pollock's residence on the date agreed upon. The reply drafted by the subcommittee was presented, considered clause by clause, amended and passed. The honorary secretary (Mr. H. Percy Dunn) was instructed to have the letter type-written, to sign it and despatch it in due course. He also laid upon the table the letter forwarded to Mr. Holmes by the secretary of the College in acknowledgment with thanks of the first resolution brought forward on behalf of the Association at the annual general meeting held at the College on Nov. 3rd. The honorary secretary was instructed to call a meeting of the committee immediately on the receipt of an answer from the official of the College referred to above. This concluded the business of the meeting and the committee adjourned.

#### PERIODATES IN CHOLERA.

THE full and circumstantial account of trials of the periodates in the treatment of cholera cases at Hamburg which appeared in *The Times* of Nov. 18th cannot fail to have attracted attention, but we do not think that the publication was happily chosen. We may say at once that a letter embodying these statements was sent to us, with a request for its insertion in *THE LANCET*, but we adhered to our rule to admit to our columns only subjects of treatment which come from duly qualified medical men. Details such as are given in the statement are hardly those which should be placed before the public eye at any time, much less when they deal with a new method the success of which can only be fully gauged after a thorough investigation by experts. The lamentable results upon the public mind of a similar publication a few years back of a new remedy for tuberculous diseases can hardly be forgotten, for the false hopes raised by it must be vivid in the memories of many people. Then, too, in the case of this recently vaunted remedy, it must be borne in mind that towards the close of an epidemic of cholera the type of the disease generally grows milder, and recoveries are in larger proportion under any plan of treat-

ment. The statements made as to several of the patients being rescued from a moribund state by the administration of periodates—the action of which can only depend on the readiness with which they give up free iodine—cannot obviously be criticised until they are properly endorsed by the responsible medical officers in charge of these patients. Without in the least objecting to the trial of any remedies that are likely to be of service in the treatment of this severe malady we must yet deprecate the drawing of too hasty conclusions, and, above all, of the presentation of facts as to the trial of such measures, except before a medical tribunal and with duly accredited medical authority. We prefer therefore to suspend judgment until the latter course is taken.

#### NOTIFICATION AT LEITH.

It is startling to learn that in North and South Leith from Nov. 7th to Nov. 9th eighty-eight new cases of measles and twelve of scarlet fever occurred in one practice there, and that none of these cases were notified to the sanitary authority. We are not aware if measles is a notifiable disease at Leith, and there is still some general doubt as to the usefulness of its notification. But with regard to scarlet fever the case is different, and we cannot help thinking that the Leith authorities should take immediate cognisance of the alleged omission to notify the above-mentioned cases. Even with regard to measles, the health authority should know something about it, in order to take proper measures with regard to the closing of schools and exclusion of scholars.

#### THE ASYLUMS BOARD HOSPITALS.

THE hospitals of the Board continue to be abnormally full of fever cases. The number of patients in them on Nov. 12th showed an increase of sixty-four over those remaining at the end of the previous fortnight. The greatest number of admissions was at the Eastern Hospital (206) and the South-Eastern Hospital (202). Already there are more than 4000 cases isolated in the hospitals, including the two large convalescent institutions at Winchmore-hill and Gore Farm. In view of the energetic efforts which the Board is making to cope with the extra work it is hard to criticise closely the fact that a few cases here and there fail to get removed to hospitals.

#### TAKING THE OATH.

WE rejoice to see that the more cleanly mode of oath administration so often advocated in these columns has passed from the stage of discussion to that of practical application. We may remind our readers that Clause 5 of the Oaths Act, 1888, was framed on lines suggested by annotations which appeared in THE LANCET shortly before the passing of that Act. It was suggested that those who preferred to swear with uplifted hand instead of kissing the book should be permitted to do so. This more cleanly mode of adjuration has always been practised in Scotland and in the Channel Islands, but in no other part of the United Kingdom. Dr. Gordon Hogg, the newly elected coroner for the Western Division of Middlesex, has not only explained to jurors and witnesses that they can claim to be sworn with uplifted hand, but has strongly urged it as the more solemn method and as being free from any risk of infection, a by no means remote probability, seeing that *inter alia* jurors and witnesses must sometimes come from infected houses. Apart from this there is the objection which must always attend the handling and kissing of a book in indiscriminate use. Unless some movement is made by the presiding officials of courts of law this excellent clause of the Oaths Act must remain a dead letter. It ought to be extensively printed and posted on the walls of all courts, so that every juror, witness and person likely to be called upon to take an oath may be aware of the privilege which the Act

confers. It may be taken for granted that very few would prefer to be sworn "on the book" if they were made aware that they have a choice in the matter. Dr. Gordon Hogg deserves the thanks of the profession and of the public for so courageously taking the matter in hand, and it is to be hoped that his example will be rapidly and generally followed by other coroners, magistrates and judges.

#### SMALL-POX CASES IN ISLINGTON.

MR. HARRIS, medical officer of health for Islington, with commendable promptitude on Monday last intimated to the medical practitioners of the parish the fact that in the last five days he had received notifications of twelve cases of small-pox within his district. We are glad to learn that up to the time of our going to press there are no further notifications. To be forewarned is to be forarmed. The public seem to be under some impression that this disease has changed its character. The profession is under no such delusion. Perhaps boards of guardians and other sanitary authorities will begin to wonder whether they have been doing their full duty in regard to the promotion of public vaccination.

#### INFECTIOUS DISEASE IN THE BOLTON RURAL DISTRICT.

IT is reported that no less than fifty-three cases of infectious disease were notified in the Bolton rural sanitary district during last October. Most of these were cases of scarlet fever and enteric fever, and occurred chiefly at Tong. The authority's hospital at Rumworth is said to be full, and it is stated that cases have had to go to the workhouse hospital. It is gratifying to know that the health officer has emphasised the necessity of further hospital accommodation being provided. This is all the more necessary inasmuch as small-pox is announced to have appeared in the town of Bolton, and a case of that disease has been already isolated in the borough fever hospital. Having regard to the definite appearance of small-pox in Yorkshire and Lancashire towns, particularly in Warrington, it is extremely important that all sanitary authorities in this part of England should be provided with means of isolating any cases that may arise. But it is equally important that these should be so placed and constructed as not to defeat the object of their existence by themselves becoming foci of small-pox infection.

#### TYPHUS FEVER IN DUNDEE.

A SMART epidemic of typhus fever is reported from Dundee. Already more than twenty cases of the disease are isolated in hospital there. Pending more precise inquiries, it is stated that the disease has originated from a quantity of rags belonging to hawkers, which were deposited (how is not stated) in a certain house. In the meantime every effort is being made to limit and localise the outbreak. With this view the health officer has very properly suggested the institution of a sort of "quarantine house," where all those who have been in contact with any patients suffering from typhus fever should be detained for a time. We shall look for further particulars of this Dundee outbreak at an early date, and should like to know if, as was the case at Wigan, the Irish quarter was the one principally affected.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Algiers.*—Dr. Brault has been appointed Lecturer on Surgery and Midwifery.

*Ghent.*—Dr. E. W. Eeman has been promoted to the ordinary professorship of Special Pathology and Therapeutics of Internal Diseases and of Laryngology, Otology and Rhinology.

*Lille*.—Dr. Bayrac of Lyons has been appointed to the post of Chief of the Department of Practical Chemistry.

*Montpellier*.—Dr. Ville has been appointed to the Professorship of Medical Chemistry.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Isidor Henriette, Professor of the Diseases of Children; Dr. Antonio Garcia Cabrera, Professor of Anatomy in the University of Granada; Dr. Paoli, General Councillor of Salice, Corsica; Dr. Pietro Pellizzari, Professor of Dermatology and Syphilography in the Florence School of Medicine; and Dr. Emilio Fasola, *privat-docent* in Midwifery in Florence.

THE Glasgow Police Commissioners have given an intimation that cases of small-pox have appeared in every district of the city. In the hope that a further spread of the disease may be checked, the commissioners urge upon the citizens the importance of protecting themselves and their dependents from the scourge by promptly securing the revaccination of every person above ten years of age. Arrangements have been made for free vaccination in the case of those who are unable to pay for the performance of the operation. The course adopted by the Glasgow Commissioners in respect of the prevalence of small-pox in the United Kingdom seems to have been followed at Warrington by the gratifying result of effectually checking the progress of the malady. A fortnight ago as many as seventy-one new cases of the disease were reported in one week; last week there were only twenty-nine fresh attacks announced, and it is expected that this week a still further diminution in the new cases will be noted.

THE question of reform in the management and the registration of common lodging-houses has engaged the attention of the London County Council. The subject is of great importance, and one worthy of the prompt interference of the Legislature. It is satisfactory to find that as the result of an interview with the Home Secretary a deputation from the County Council received an assurance from the hon. gentleman of his complete sympathy with the object of the deputation, and of his desire to promote it by considering whether the control of lodging-houses could be carried out by the exercise of the Ministerial power of transfer under Section 10 of the Local Government Act, or would have to be effected by Act of Parliament.

AT a meeting of the Metropolitan Branch of the Incorporated Society of Medical Officers of Health, held on Nov. 17th, it was resolved, on the motion of Drs. T. Orme Dudfield and J. S. Bristowe, "that in the opinion of this meeting of metropolitan medical officers of health the permanent hospital accommodation of London for infectious diseases is insufficient and in the interests of the public health should be increased forthwith, and that copies of the above resolution be forwarded to the Metropolitan Asylums Board, the Local Government Board and the London County Council."

A MEETING of the Council of the Metropolitan Hospital Sunday Fund will be held at the Mansion House to-day (Friday), at three o'clock. The business of the meeting is to determine the report of the Council for the year 1892 and to order its publication; to revise the list of the Council for 1893; to order the convening of the next annual general meeting of constituents; and to consider what day of 1893 shall be recommended to the constituents for next Hospital Sunday.

SIR JAMES CRICHTON BROWNE, M.D., F.R.S., will this (Friday) evening preside at a dinner of the staff and past and present students of the National Dental Hospital and College and their friends. The festival will be held at the Royal Venetian Chamber of the Holborn Restaurant at 6.30 P.M.

THE Royal Commission on Vaccination assembled on the 23rd inst., Sir James Paget being in the chair. Dr. John McVail attended and gave evidence in favour of compulsory vaccination, quoting statistics to show the value of the operation as a preventive of small-pox. We understand that an interim report will shortly be submitted to Parliament.

THE second Grocers' Scholarship Lecture on the Physiology and Pathology of Blood Destruction will be delivered by Dr. William Hunter at the Examination Hall, Victoria Embankment, on Tuesday, the 29th inst., at 4 P.M.

THE Bradshaw Lecture will be delivered by Mr. Christopher Heath at the Royal College of Surgeons on Thursday next, Dec. 1st, at 4 P.M. The subject of the lecture will be Diseases of the Nose.

THE death is announced of Mr. Henry Whiting, M.R.C.S., L.S.A., of Haslemere. The deceased practitioner was for a number of years a medical adviser of the late Lord Tennyson.

THE Royal Microscopical Society will hold a conversazione in the Banqueting Saloon, St. James's Hall, on Wednesday, Nov. 30th, at 8 P.M.

THE death is announced of Dr. Axel Iverson, professor of surgery at the Communal Hospital, Copenhagen, on the 22nd inst.

BRIGADE-SURGEON HAMILTON, M.D., will read, on Dec. 5th, at the Medical Society of London, a paper on the Nature of Cholera.

## THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE winter sitting of the General Medical Council commenced on Monday, Sir Richard Quain, President, in the chair.

Mr. W. C. J. Miller, Registrar, presented the official notification of the appointment of David Caldwell McVail, M.B., as Crown nominee for Scotland, in room of the late Sir George H. B. Macleod.

Dr. P. Heron Watson formally introduced Dr. McVail to the President and the Council.

#### *The President's Address.*

THE PRESIDENT then addressed the Council. He said: On this occasion, being the fifty-third session of the Council, we miss the presence of our esteemed colleague, the late Sir George Macleod. We miss his dignified presence, we shall miss his words, not too often spoken, but always wise, always expressed in a kind and conciliatory spirit, always helpful in the discharge of our duties. I am confident that there is no one of those whom I now address, and who has had the privilege of sitting as the colleague of Sir George Macleod, but will deeply lament his loss to us as well as to his many friends. His place will now be occupied by Dr. David Caldwell McVail, who is not quite a stranger to the Council, for he has been already our colleague from June, 1886, to April, 1888. I have every reason to anticipate that, following the example of his distinguished predecessor, Dr. McVail will be found a useful and acceptable member of our body. I do not propose to occupy valuable time by lengthened observations of my own. I am anxious, as

no doubt you are all likewise, that we should proceed at once to the discharge of the important duties assigned to us by law. Let me say that we must never forget what these duties are. They are, in the first instance, the promotion and advancement of medical education, so as to ensure for the public competent and well-qualified practitioners; and, in the second place, to take care that the Medical Register is not stained by retaining on its pages the names of those whose conduct is such as to render them unworthy to remain members of the medical profession. These, with the preparation of the national Pharmacopœia, are our duties. I mention them thus specially because demands are constantly made upon the Council to undertake other duties, which are not in accordance with those assigned to us by law, and with which we can have no relation. With reference to the several occurrences which we have to note since the last meeting of the Council, I have to mention that, in accordance with the resolution passed on May 25th last, I caused a statement to be prepared by the solicitor to the Council, with reference to the conditions under which foreign medical practitioners are allowed to practise in this country, with a view to procuring, if possible, a reciprocity of privileges for English practitioners desirous of practising amongst their own people abroad. This statement was submitted to the Lord President of the Council, who communicated it to the Foreign Secretary, with a request that it should be forwarded to the several foreign Governments. It will be seen in the programme that attention was specially given to the subject by the English ambassadors in France, in Italy and in Switzerland. The result seems to indicate that though there will be greater restrictions than hitherto on the practice of English medical men in France, still these restrictions may not prove very oppressive. In the kingdom of Italy it may be said that there is no restriction on English practitioners. With regard to Switzerland, the English representative at Berne writes to Lord Rosebery as follows:—"Although I shall lose no opportunity of urging on the Federal Government the justice of granting to British medical men in Switzerland the same privileges that Swiss practitioners enjoy in Great Britain, I cannot hold out to your lordship much hope of my being able to obtain a relaxation of the present rule, which renders it incumbent on British medical men who are desirous of practising in this country to obtain the Federal diploma by passing the regular medical examination. However well disposed the Federal Government may be to act in a liberal spirit and to conclude an arrangement of reciprocity, the Swiss Medical Board, which has a decisive voice in such matters, remains firm in its opposition to any idea of reciprocity arrangements with foreign countries." Thus English practitioners, to whom is especially due the recognition of the health resorts in Switzerland, are debarred by the action of their medical colleagues in that country from attending on patients whom they send to those almost inaccessible mountain regions, from which, in case of difficulty or danger, escape is nearly impossible, and where most of all they would need the special care of their best friends—their English physicians. It would really be well that we should bear these facts in mind in reference to Switzerland, and consider whether we should not send our patients to other lands, where they can obtain all essential climatic advantages, still enjoying the privilege of being attended by medical men of their own country; or might we not recommend voyages by sea, for which great facilities are now offered, and which in many instances possess advantages over those Swiss mountain valleys where the climate is often unsuitable and even hurtful in certain forms of disease? Nay, may we not frequently regard some of our own winter resorts with more favour? In accordance with instructions given to our solicitor for the purpose of obtaining information on the subject, Mr. Farrer has communicated with the authorities at the Home Office and the Metropolitan Police. Both have informed him that they will direct the reports of convictions for felony or misdemeanour of medical and dental practitioners to be communicated to the Council. A form of return, as requested, has been prepared and placed at the Home Office and at Scotland Yard. Several of these returns have been already sent in; some of them, however, relate to non-registered and non-qualified practitioners. In this incident there is, however, an advantage, inasmuch as the authorities will have an opportunity of discovering the false statements of individuals who assume the rank of qualified medical practitioners to which they have no claim. The visitation and inspection of examinations have been made in the case of the Irish universities and the Scottish corporations. The reports on

these visitations have been forwarded to the several medical authorities concerned, and their comments thereon, together with the reports, will be placed in the hands of the Committee on Education when received. Arrangements are in progress for the visitation next year of the medical corporations in Ireland and some of the English universities, and several of these visitations will be completed before the meeting of the Council in May next. In accordance with the resolution of the Council on the subject of "covering" by dentists, which was referred to the solicitor with a request that, after communicating with the Dental Association, he should report to the executive committee at the present meeting, the solicitor has presented a report to the effect that it seems to him as much a duty of the Council to protect the public in the matter of dentistry as in medical practice. He advises the Council to issue a warning to dentists, through the medium of the British Dental Association, who are willing to undertake the duty, similar to that conveyed by means of a minute of the Council to medical practitioners before taking more decided action in regard to the offenders. I cannot conclude these few observations without remarking that year by year the duties devolving on the Council become more and more definite, more and more important and lead to more decided practical results. I can well understand that in the early and difficult days of the existence of our Council the duties were unfamiliar to many of its distinguished members, and that they found considerable difficulty in formulating and surmounting some of them. Then, too, it was thought and expected from the outside that much more could be accomplished by the Council than it had authority for doing. It is now recognised—and it is my hope that it will be more and more recognised every year—that the Council is doing all in its power to secure the higher education of the profession and to elevate and maintain its character in all that is essential in connexion with the welfare of the public within the lines marked down for us by Parliament. I can recognise that this Council, which I can better understand in my present position, composed as it is of the representatives from the great teaching and licensing authorities of the country, of representatives of the Crown and of representatives elected by the profession at large, should be, and is, a body well constituted to perform these important duties. In some other countries these duties devolve on Government officials; happily here they are placed in our own hands, and I am confident that we shall not fail to prove worthy of the trust thus reposed in us.

On the motion of Sir JOHN SIMON, seconded by Sir WALTER FORSTER, M. P., a vote of thanks was passed to the President for his address.

#### *Business Committee.*

Mr. Wheelhouse (chairman), Sir William Turner and Mr. Bryant were appointed the business committee, to continue in office for one year from the present date.

#### *The Arrangement of the Programme.*

Sir JOHN SIMON, raising a point of order, said that when he received the provisional programme he observed on it, as a remnant from last session, a notice of motion to be proposed by himself and seconded by Sir Dyce Duckworth, relating to proceedings taken in this Council. But when he got the programme that day he saw the notice of motion was absent, and he received at the same time a note from the Registrar stating "that certain documents and resolutions, proposed to be laid before the Council, are withdrawn on the advice of the solicitor, because they referred to a cause now pending in the courts of law." That was a resolution of the Executive Committee. Might he ask what these documents were? He was not aware that they referred to a case pending in the courts of law in regard to any proceedings in this Council, and in the interest of members he expressed his dissent from the view that the Executive Committee was at liberty in this offhand manner to suppress that notice of motion. Again, on turning to the minutes of the Executive Committee, he found no notice taken of the resolution.

The PRESIDENT said the resolution in question was come to on the previous day, and to his mind it was impossible for them to act otherwise. They could not separate Sir John Simon's resolution from other documents which followed, and if it were printed and discussed all must be discussed.

Sir WILLIAM TURNER said the Executive Committee considered the matter with great care. The solicitor spoke without the slightest hesitation and put it as strongly as this—that if this question were discussed by the Medical Council he felt it would be tantamount to a contempt of court.

The committee felt that they could not fly in the face of the very decided opinion given by their solicitor.

After some further discussion it was resolved to record the resolution in question on the minutes of the Executive Committee, and the subject dropped.

#### *Examinations for the Army Medical Staff.*

A table was received showing the results of the competition for commissions in the medical staff of the army in August last. It appeared from the document that the total number who presented themselves was 43. Of these, 20 passed for vacancies, 10 qualified, but were unsuccessful; 13 were rejected, 13 were deficient in medicine and 9 in chemistry and drugs. The Director-General of the Army Medical Department informed the Registrar that four candidates were deficient in spelling.

The REGISTRAR, in response to a request for the information, said that one of the four candidates passed the matriculation examination of the Royal University of Ireland, one the examination of the College of Preceptors in London, and two the preliminary examination of the Royal College of Surgeons in Ireland.

Sir W. FOSTER, M.P., moved that these bodies have a letter sent to them by the Registrar calling attention to the fact.

Mr. MAONAMARA seconded the motion. He considered it one of the most important duties they had to see that the preliminary examinations were kept up to the mark. He regretted very much that two of these gentlemen passed the preliminary examination of the College he represented, and he would be only too pleased to have an intimation from the Council conveyed to them in an authoritative manner. The College of Preceptors—a body which had been tried to be thrust down their throats there on several occasions—had also fallen short in its preliminary examinations. But it must not be thought there had been an all-round failure on the part of the candidates. It was in spelling, and he knew one of the most distinguished members of the English bar who, when he wrote a letter, was obliged to have a dictionary beside him to prevent mistakes in spelling.

Sir J. BANKS said the preliminary examination of the Royal University of Ireland was second to none, and he could not understand how one of these four men passed it, and he regretted it extremely.

The motion was agreed to.

Dr. HERON WATSON moved that the thanks of the Council be given to the Director-General of the Army Medical Department for his kindness in sending this return, and also in giving the information about the spelling.

Dr. BRUCE seconded the motion, which was agreed to.

#### *Medical Aid Associations.*

The next business was to receive communications from the Medical Defence Union and the Gloucester Friendly Societies' Medical Association in regard to medical aid associations. Both were long documents. That of the Medical Defence Union, written by Dr. Leslie Phillips, the secretary, was accompanied by some printed official reports of several medical aid associations in various parts of the country, which, he said, would sufficiently substantiate what he presented in the way of argument, and would reveal the condition of servitude to which the system carried out by medical aid associations had reduced many honourable members of the profession, who only sought the opportunity to escape from the thralldom into which they had drifted or been driven by stress of circumstances. The condition of affairs was alike derogatory to the honour of the profession and injurious to the best interests of the public. A medical aid association was a business generally formed by the amalgamation of the existing medical clubs in any particular town. Having once amalgamated into a medical aid association they throw open their doors directly or indirectly to any and every comer. But brief consideration, declared Dr. Phillips, was needful to see that the system of these associations was a sweating one. The skill, industry and labour of medical men were made use of to accumulate wealth for what was no more nor less than a trading company. The medical man was reduced to a condition of servitude; he was paid a miserable pittance; the greater proportion of his earnings was taken by the proprietors, not only to pay fees but to accumulate assets; the right to freely practise his profession was denied him, or only allowed on consideration that his earnings were divided between himself and his masters. Many, if not most, of these aids did not confine their sphere of operations to these *bonâ-fide* members of the amalgamated clubs, but practically carried on private and general practice among all comers, not so much for the

benefit of the medical officer as for their own emolument. They were, in other words, large unqualified corporations, carrying on medical practice under cover of one or two medical officers, to the destruction of the interests of the resident practitioners of the town. Another way of viewing the same thing was that the surgeon actually paid a tax upon his industry. Many of the associations were good enough to permit their medical officer to attend midwifery cases, but, in consideration of their kindness, they required that a part of the fee should be paid into the exchequer of the association for the benefit of its general funds. Each year the formation of medical aid associations was increasing more and more, and a definite disclosure of policy on the part of the Medical Council would serve not only to bring about a better understanding between the existing associations and their medical officers, but would prevent the extension of what all fair-minded men, both professional and lay, must regard as an iniquitous system. It appeared to him that it was not essential for any public inquiry to be made in this matter. Recent events and investigations had convinced him that a potent remedy would be a clear and unambiguous note of warning addressed by the Council to the medical profession, and especially to those associated with these medical aids. He suggested that a practical solution of this grave question, even if the Council did not see its way to declare it infamous in a professional respect for a medical man to engage himself to exclusively practise for and on behalf of a medical aid association, foregoing the right to privately practise his profession, or submitting to division of profits resulting therefrom, would be for the Council to declare it to be conduct infamous in a professional respect for any medical man to hold the office of medical officer to a medical aid association save and except under the same rules and usages as ordinary club appointments were held by the resident medical men in any particular town. The communication from the Gloucestershire Friendly Societies' Medical Association denied the charges contained in the letter from the Medical Defence Union, and defended the methods adopted by these associations, which, it was explained, owed their origin to a desire to remedy the abuses which accompanied the old club system, and which, it was declared, an impartial inquiry would show to be free from the evils alleged against them.

Mr. WHEELHOUSE moved: "That the General Council approach the consideration of the question of medical aid associations, and the evils said to be attendant upon them, by referring the whole subject to a committee authorised to take evidence, and after fully sifting the matter to report at the next session of the Council, the committee to consist of the following six members: Dr. Glover (chairman), Mr. Wheelhouse, Mr. Teale, Dr. Macalister, Dr. Leech and Dr. Bruce." He asked that this method of dealing with a very large question be adopted by the Council, because he felt that if they were to come to an immediate decision on a question of so much moment—a question which had agitated the profession throughout the country—they might very likely be guilty of hasty legislation on the subject. By means of a committee all parties would have their views fully presented and considered before the Council was asked to come to any decision on the matter. He asked for the purpose that the committee should be authorised to sift the matter really to the bottom, and be empowered to take evidence if necessary and to receive information from whatever quarter it might seem desirable.

Sir W. FOSTER, M.P., seconded the motion.

Dr. HAUGHTON said he felt extremely thankful that the name of no Irishman appeared on this proposed committee. There were five Englishmen and one Scotchman, and he hoped Dr. Bruce was pleased with the company he was in. This was a testimony which was gratifying to his (Dr. Haughton's) innermost heart of hearts as an Irishman that this disgraceful process of sweating medical practitioners did not exist on the other side of St. George's Channel. He felt so strongly upon this matter that he was prepared to vote that this practice was infamous in a professional point of view, and he hoped that the result of the committee would be to ask him for his vote in that direction.

Sir JOHN SIMON thought that the question of whether the public suffered by this practice ought to be considered; and if they found that injury was inflicted on the public by it, clearly it was within the province of the Council to deal with it. As regards the other questions, however, he was of opinion that they were questions for the British Medical Association and other medical associations to deal with.

Dr. GLOVER thought the Council would be entirely right in taking the course proposed of first examining the facts of the case. He wished to know whether the committee would be entitled to ask the assistance of the solicitor of the Council, as that seemed to be a very important matter.

The PRESIDENT: Certainly.

Sir W. TURNER asked if it was to be understood that the expression in the motion "authorised to take evidence" was intended to give authority to the committee to call persons before it.

Dr. GLOVER: I should distinctly be in favour of examining in person.

Sir W. TURNER observed that, though this might seem a very simple matter on the surface, there was something very important below. There was the question of expense. If they were to take evidence it must be presented to the Council in such a way that the members might sift it before coming to an ultimate decision. Was the evidence to be taken down in shorthand and then extended, and if so, who was to pay the cost? If the motion were to be read as Dr. Glover obviously read it, he hardly thought the question of the cost had been sufficiently considered. If they were to have evidence in this way the Council, he presumed, must bear the cost.

Dr. GLOVER had no hesitation in saying that this was an expense that the Council should willingly and cheerfully accept. He could not imagine a more useful purpose to which to apply some of their surplus than in providing a complete account of the evidence before the committee. But he did not anticipate that it would be necessary to examine many witnesses.

Sir W. FOSTER, M.P., regretted very much that the question should have been approached from an economic point of view with regard to the funds of the Council. They had before them a very grave complaint made on behalf of the general body of the profession, from whom the funds of the Council came. They complained, first of all, that this system was demoralising; and, secondly, that it was more or less injurious to public health, by bringing about a defective method of the practice of the profession. Those were two very grave accusations and they stretched over so wide a field that if they were to take notice of the matter at all it should not be in any spirit of haste or carping economy, but they must be prepared to go into the whole subject deliberately and sift it to the very bottom in order to arrive at a wise conclusion that would not be easily upset. If it were necessary that the inquiry should cost £1000, he thought they could not spend the money better than for the benefit of those who found it. He hoped therefore there would be no more objection to the proposal on financial grounds.

Sir JOHN SIMON had great doubts about the desirability of the committee at all, but if they were to have an inquiry and the committee found it necessary to incur expense, it should be a limited expense under the direction of the Executive Committee.

Dr. HERON WATSON pointed out that in addition to the cost of reporting the evidence there would be the expense of bringing witnesses to London. He asked whether the members of the committee were to be paid their expenses while sitting. Was the expense, whether £1000 or £2000, to be paid by the General Council or by the English Branch Council? It seemed to him that this was a question confined wholly to England. In Scotland, happily, they knew nothing of it, nor did they in Ireland, and he did not see why the Irish and the Scotch branches of the Council should be charged with any of the expense.

Dr. GLOVER said it happened that the English public and the profession in England were the sufferers, but they should have to know more than they did now before they could say that Scotch practitioners were entirely free from blame in this matter. He hoped the Council would not prejudice any aspect of the question and would insist on the power of the committee to take evidence. If it had not that power it should not be appointed. He had no reason to suppose that medical witnesses would be unwilling to come even at their own charges, and he believed the representatives of the friendly societies would be willing also.

Dr. HERON WATSON asked whether the members of the committee would be paid.

Dr. GLOVER: I do not wish to be paid.

Dr. HERON WATSON said he should like to hear that from every member of the committee.

Sir W. TURNER said there must be a limit to the expense.

Mr. MACNAMARA could not see the necessity for any great or searching inquiry. It was the principle, which had to be

considered, and he thought they had discussed the matter sufficiently to enable them to come to a decision. They would not be in a better position to enter on the question when the committee reported.

Mr. WHEELHOUSE said the authority to take evidence was desired for the purpose of supplementing written evidence, if the committee should think it necessary to verify statements in such documents by means of cross-examination. He never entertained any desire to be paid for his services on the committee, and he believed that was the feeling of all his colleagues.

After some further discussion,

Sir DYCE DUCKWORTH moved and Sir W. TURNER seconded the following rider: "But that the committee do not incur expenditure beyond £100, without the previous sanction of the Finance Committee."

Sir W. FOSTER, M.P., did not think that was treating the committee with any great confidence. However, as he was not a member of the committee, he did not care to resent it, and, if Mr. Wheelhouse agreed to the addition, he made no objection.

Sir W. TURNER said it was not a question of confidence in the committee, it was purely a business matter.

The proposal of Sir Dyce Duckworth having been accepted by Mr. Wheelhouse, the motion as amended was then agreed to.

#### *Midwifery Diplomas.*

The next business was a memorial from Dr. R. R. Rentoul with regard to the action of those registered medical practitioners who have formed schools of midwifery and examining bodies granting diplomas for the practice of midwifery, and praying that the Council would consider the making of a rule restraining such action on the part of these practitioners as being contrary to the Medical Acts.

Mr. WHEELHOUSE explained that Dr. Rentoul had presented two documents, one with the memorial and the other containing a large amount of evidence which had been brought together by Dr. Rentoul with regard to the memorial. He hoped the Council would take the memorial into consideration, because the question with which it dealt was one which was agitating the profession very profoundly indeed. He had letters before him from members of the profession entreating him, as one of the direct representatives, to use his best endeavours to have the matter considered by the Council. It was considered that the certificates given by those persons who undertook to examine women in midwifery questions were practically diplomas. They stated upon the face of them that the holders had been examined and that they were found competent to attend midwifery cases. They were used as diplomas all over the kingdom, and it was in order that the rights of the medical men on the one hand and those of the public on the other should be considered that Dr. Rentoul was agitating in the matter. He (Dr. Rentoul) said that the law demanded that those who practised midwifery should also have been educated and examined in medicine and surgery, and that unless they had been so educated and examined they could not be said to be competent to practise any one of the three branches. Indeed, he went so far as to say that if certain bodies were to be allowed to give certificates that persons were competent to practise midwifery, might not other combinations of medical men give certificates that they had examined persons in surgery and medicine, and certify that those persons were fit and competent to practise those branches? Dr. Rentoul appealed to the Council to put a stop to a practice on the supposition that it was detrimental to the profession and the public that those persons should be authorised to practise only one branch out of three which the law said they should be instructed in, but he forgot that the duty of the Council was only to see that such persons were not entered upon the Medical Register. If the Council were guilty of permitting any one of those persons to enter the Medical Register, then there would be cause for complaint. In the meantime, however, Dr. Rentoul entreated the Council to consider the question of the propriety of any body such as the London Obstetrical Society issuing certificates in the form of diplomas stating that it had examined and certified certain women as fit to practise midwifery. If the certificate could be so altered as to show that the women had been educated and examined and were certified to be capable obstetric nurses then he (Mr. Wheelhouse) thought the whole question would subside at once. He moved that the memorial be printed in the minutes of the Council.

Dr. ATHILL seconded the motion.

Sir WILLIAM TURNER pointed out what he regarded as a

fundamental error in Dr. Rentoul's case. The certificates in question had no legal value; they were simply an expression of opinion on the part of one or more individuals.

After some further discussion, the motion was agreed to.

#### *Application for Restoration.*

Mr. DAVID HYMAN DYTE petitioned for restoration to the Medical Register, from which he was removed in May of the present year. The Executive Committee recommended the Council to grant the petition; but after considering the matter in private for some time the Council decided not to do so.

#### *The University of Bombay.*

The Executive Committee reported that an Order in Council applying Part II. of the Medical Act (1886) to India having been received from the Privy Council Office, they had considered an application from the University of Bombay requesting the recognition of the degrees in Medicine and Surgery of that University and their registration in the Colonial Register, under Section 13 of the Medical Act (1886), and on Nov. 21st, 1892, passed the following resolution, viz.: "(1) That this application be acceded to so far as appertains to graduates of the University of Bombay who commenced the study of Medicine prior to Jan. 1st, 1892, but that the Executive Committee would call the attention of the University of Bombay to the recent regulations of the General Medical Council, which require that candidates who commence the study of Medicine after the above date should be engaged in professional study for five years; (2) that the recognition of these degrees of the University of Bombay be reported to the General Council."

Dr. HAUGHTON protested against the recognition of these degrees.

Mr. BRUDENELL CARTER asked the registrar whether in this matter the Executive Committee had not done something which was well within their powers.

Mr. MILLER replied that certainly this was the case. By resolution of the Council the Executive Committee were empowered to take the necessary steps for carrying into effect the clauses of the Medical Act of 1886 relating to the registration of the diplomas of colonial and foreign practitioners, and were instructed to report their proceedings to the Council from time to time.

Dr. HAUGHTON: Then all I have to say is that this Council has entrusted to the Executive Committee a task which they are incompetent to discharge.

#### *Covering by Dentists.*

The next business was a report by Mr. F. W. FARRER, the solicitor of the Council, with reference to the statement submitted to the Executive Committee by the British Dental Association. Mr. Farrer explained in this report that the statement of the Association mentioned fourteen cases of covering by dentists of such a character as would, if proved against a medical practitioner, involve the removal of his name from the Register. It seemed to him to be as much the duty of the Council to protect the public in the matter of dentistry as in that of medical practice. The Executive Committee would, however, recollect with what care the Council proceeded in the case of medical practitioners, what years of warning it gave them, how it promulgated a minute upon the subject and took the utmost pains to convey the minute to every medical practitioner, and how several cases were tried and practitioners warned before any name was taken off the Medical Register for the offence of covering. He would advise the Council to issue a similar warning to dentists, and to cause such warning to be conveyed to every dentist on the register through the British Dental Association, who had expressed their readiness to undertake the task. Looking to the position of a very large number of dentists and to the mode in which they had been in the habit of practising, he thought that covering in their case should be dealt with even more cautiously, if possible, than it was dealt with in the case of practitioners on the General Medical Register.

Sir W. FOSTER moved that the solicitor be directed to prepare a draft warning to registered dentists against the employment of unqualified assistants analogous to that given to registered medical practitioners on April 21st, 1888, and that the draft warning be submitted to the Council. The duty of the Council, he said, was to give all the help they could to the dental profession in putting down what was an illegal and undesirable practice.

Dr. GLOVER, in seconding the motion, said he was very glad that the Council had come to see the propriety of

extending the same principle as to covering to the dental profession as they had extended to the medical practitioner.

The motion was agreed to, and it was arranged that the draft warning should be submitted to the Council before the close of the present meeting.

#### *Proposed Amendment of the Standing Orders.*

A long discussion took place with reference to an amendment of the Standing Orders proposed by Dr. BATTY TURK. The amendment was framed with a view to meet a difficulty which arose some time ago in Edinburgh in connexion with the withdrawal of a qualification. The discussion resulted in a reference of the whole question to the Executive Committee for consideration and report during the present meeting.

The Council then adjourned.

WEDNESDAY, NOV. 23RD.

The Council resumed, Sir Richard Quain, M.D., President, in the chair.

#### *Medical Aid Associations.*

A communication in regard to Medical Aid Associations from the Wolverhampton Friendly Societies' Medical Association, calling in question the statements made by the Medical Defence Union and submitting a copy of their balance-sheet, and a memorial from Mr. W. R. Barclay, M.B., C.M. Aberd., in regard to the action of the Medical Aid Associations in Northampton, were referred to the special committee appointed on the previous day to inquire into and report on the subject.

#### *Dublin University Medical Examiners.*

Dr. HAUGHTON moved: "That, inasmuch as the reply of the medical examiners of the University of Dublin to the report of the visitor and inspector of the Medical Council (May-June, 1892) is already in the hands of the Registrar, it shall be considered at the present session of the Council." He was there, he said, to support a very important principle—a principle which had been recently violated by the friends of Sir Walter Foster, who was to second the motion—by first condemning a party and proceeding afterwards to inquire into the case. The principle was much older than Mr. Morley or his master, Mr. Gladstone, because it went back to the time of Rhadamanthus—an authority which even this Medical Council could not refuse to accept and acknowledge. Was this Council prepared to adopt the highly judicial authority of Rhadamanthus and say that, the University of Dublin medical examiners having been put on their trial, their reply was not to be considered? There was a principle of fairplay involved in the matter, and it was but fair and right that the report and the reply to it should be considered now and not postponed until some of them, including himself, were lying in their happy graves.

Sir W. FOSTER, M.P., seconded.

Dr. HERON WATSON doubted whether the Council was at present in a position to do what Dr. Haughton asked.

Mr. MACNAMARA supported the motion.

The debate was adjourned in order to proceed with the penal cases.

#### *The Case of Dr. W. Maunsell Collins.*

The next business was the consideration of the case of William Maunsell Collins (registered as M.D., Mast. Surg., 1866, Q. Univ. Irel.), who had been summoned to answer a charge of having been convicted of a felony. Dr. Collins appeared along with his counsel and solicitor respectively, Mr. C. F. Gill and Mr. Arthur Newton.

Mr. FARRER, solicitor of the Council, explained that on June 27th last, at the Central Criminal Court, Dr. Collins was convicted of forging a promissory note for £1500, and on the 25th of the following month he was ordered to enter into his own recognisances in the sum of £200 to appear and hear judgment when called upon.

Mr. GILL said that Dr. Collins submitted himself to the judgment of the Council as to whether they should think it right, in the discharge of their duty, to erase his name from the Medical Register. The Act of Parliament, he might remind the Council, made it entirely a matter of discretion whether they did so or not. There were many instances where this kind of discretion had to be exercised by other bodies. There were cases where persons who had earned pensions in the army or navy were charged with criminal offences and convicted of them, and it was a matter of discretion for the Treasury authorities whether the pensions should be forfeited. Council then proceeded to detail the circumstances in which Dr. Collins committed the offence,

and in conclusion appealed to the Council not to judge him more harshly than the Court before which he had appeared. After conferring in private the Council determined to direct the Registrar to remove the name of Dr. Collins from the Medical Register.

*The Council and the Registrar-General.*

Mr. FARRER informed the Council that other cases of complaint than those which appeared on the paper had been put before the President during the past six months, but inasmuch as they mainly turned upon certificates of death and irregularities in giving them, it was thought by the Executive Committee of the Council that such cases were properly the business of the Registrar-General, whose office it was to protect his Acts; and by the direction of the President he (Mr. Farrer) had prepared a draft letter, which would be considered hereafter by the President, to point out that if the Registration Acts were not complete, the Council would gladly join the Registrar-General in any representation to the Home Office to make them satisfactory.

Sir WILLIAM TURNER explained that the Scottish Branch Council had had sent to them two letters from the Registrar-General for Scotland upon this matter. The Branch Council would meet to-morrow, and they must reply to the Registrar-General for Scotland, and it would be a great convenience to them if Mr. Farrer could give them some idea of the form of the letter which he proposed to address to the Registrar-General for England, because they might be able to utilise it in their answer to the Registrar-General for Scotland.

Mr. FARRER agreed to produce the draft letter.

The PRESIDENT said there could not be any subject of more importance than this, because the Registrar-General rather wanted to avoid doing his duty. Well, he did not do his duty in prosecuting certain people who had subjected themselves to penal consequences.

Mr. FARRER said the Council must not say that the Registrar-General did not do his duty because he did not see his way to take proceedings in cases where they might think he should. The Registrar-General did his duty to the best of his ability, but he (Mr. Farrer) did not want the Council to do the duty which properly fell upon the Registrar-General.

*The Case of Mr. Stephen Francis Smith.*

The Council then proceeded to consider the case of Mr. Stephen Francis Smith (registered as L.S.A. Lond., 1884), who was summoned to appear on a charge of having been convicted of giving a false certificate of death and also on a charge of covering an unqualified medical practitioner. Mr. Shultess Young, barrister, appeared for Mr. Smith, and Dr. Bateman for the Medical Defence Union.

Mr. FARRER stated that Mr. Smith was convicted at the North London Police-court for having in July last, at Seven Sisters-road, made a false certificate concerning the death of Caroline Coxford and fined £10 and costs. Information and evidence had been also laid before the Council by which the defendant was charged with having been guilty of infamous conduct in a professional respect, particulars of which alleged conduct were as follows:—"That he had habitually acted as cover to an unqualified medical practitioner named C. A. Smith, permitting and enabling him to practise as if he were duly qualified, and signing medical certificates in cases attended by the said C. A. Smith and not attended by him."

Mr. YOUNG, on behalf of Mr. Smith, elected to have both parts of the charge gone into together.

Dr. BATEMAN then called attention to the evidence which had been given at the police-court when Mr. Smith was convicted of making a false certificate of death, with the object of establishing the second part of the charge. The points he wished to bring most before the Council were—first, that the defendant lived in Woodford, Essex, and that the unqualified practitioner lived in Seven Sisters-road—a distance of some miles—and that the house in that road was taken and rated in the name of C. A. Smith, the unqualified practitioner. The only defence which could possibly be urged in Mr. Smith's favour was that he happened to be out on this occasion to an urgent midwifery case. The evidence of the Coxfords clearly proved that they had never heard of S. F. Smith nor seen him at their house before their mother's death, and that they had no idea that C. A. Smith, who attended them as the assistant of a deceased uncle of the defendant, was not a qualified man and would not be able to give them a certificate of death.

Mr. YOUNG called the defendant, who stated that he had practised in Seven Sisters-road and the neighbourhood since June, 1889, when he started in practice afresh. A year and a half later he became assistant to his father, whose surgery was at Stratford. He had days and hours of consultation at Seven Sisters-road. His unqualified assistant there was about fifty years of age, and had been assistant for about ten years previously to another medical man there. He was called in by the Coxfords on July 25th, and on the following day, finding the patient very ill, he telegraphed to witness at Stratford, where he had been called to a midwifery case. He telegraphed to his assistant to call in Mr. Herring, a local practitioner, and went himself to Coxford's as soon as he could get away from the midwifery case. When he arrived the woman had been dead twenty minutes. He was paid his bill by the friends of the deceased, and he paid Mr. Herring his fee. From what he heard he was quite satisfied as to the cause of death, and no doubt had been thrown upon the cause of death as stated. His assistant was not with him now.

In reply to Dr. Bateman, Mr. SMITH said the person whom his assistant was with ten years before he took the practice was his (witness's) uncle, who died in 1889.

Mr. W. ROBERT SMITH, a Member of the College of Physicians and Surgeons (Canada) and L.S.A. London, father of the defendant, and Mr. HERRING were examined in corroboration of defendant's statement. The latter stated that he had never been called in before by Mr. Smith. He should have been inclined to sign the certificate in this case.

Dr. BATEMAN: Do I understand you to say you would sign a certificate of the death of a patient whom you had only seen in an unconscious condition, being taken there by an unqualified practitioner?

Mr. HERRING: Yes.

In reply to questions by the members of the Council, Mr. SMITH said the unqualified assistant's name never in any way appeared on the house nor on the accounts sent out. The name of the unqualified assistant appeared in the local directory as that of a medical man, but it was unknown to them both; and the information must have been given by the servant to a man who came round in connexion with the directory. He (Mr. S. Smith) rented a few rooms at the house in Seven Sisters-road for the practice, but the rest of the house was occupied by C. A. Smith, who was a married man and was rated for the premises. There was no partnership between them. The assistant received a salary of £150 a year, and the total receipts were about £400. He (Mr. Smith) was still registered as at Woodford, Essex, his father's house.

Mr. MUIR MACKENZIE: Have you any explanation to offer of your signing a certificate of the death of a patient whom you had not seen?

Mr. SMITH: I saw the deceased late at night, and the friends asked for a certificate to be sent on that night. I went home and signed it. I considered when I signed it that as the patient was a patient in my practice I was the proper person to sign it.

Mr. YOUNG then addressed the Council on behalf of his client, who he contended had not been guilty of such serious misconduct as would induce them to remove his name from the Register. His act was no doubt one of reprehensible carelessness, but not an act of infamous conduct demanding the censure of the Council, still less the removal of his name from the roll. With regard to the employment of unqualified assistants, he saw them advertised for every week in THE LANCET, and if it was an illegal thing to employ them he hoped the medical profession would very soon be made aware of the fact by an authoritative statement from the Council. Meanwhile it would be most unfair and unkind if this man was to be made the first victim of this new idea which had come over the medical world.

Replying to Sir John Simon, Mr. YOUNG said it was certainly not conceded that C. A. Smith, the unqualified assistant, was habitually treating patients without the supervision of Mr. Smith.

The Council deliberated in private, and when the public were readmitted,

The PRESIDENT informed Mr. Smith that the Council had decided not to remove his name from the register, but at the same time they cautioned him to be more careful in his relationship to assistants in future, and particularly in regard to giving death certificates.

The Council then adjourned.

THURSDAY, NOV. 24TH.

The Council resumed their meeting, Sir Richard Quain taking the chair.

*The Case of Mr. Stephen Francois Smith.*

The PRESIDENT said there had been some complaint that he had not censured Mr. Smith. He wished to explain that he had no authority under the law to censure. That question had been raised before. The Council might remove a man's name from the Register, and it might caution him, but it could not censure him.

*The Dublin University Examinations.*

The Council resumed consideration of the motion proposed by Dr. Haughton and seconded by Sir Walter Foster, to the following effect—viz.: "That, inasmuch as the reply of the medical examiners of the University of Dublin to the report of the visitor and inspector of the Medical Council (May-June, 1892) is already in the hands of the Registrar, it shall be considered at the present session of the Council."

Mr. MACNAMARA said he was strongly of opinion that the report with reference to the University of Dublin should be taken into consideration. He would be met at once with the objection that it had not gone to the Examination Committee, but he could not for the life of him say what light the committee could throw upon the question. The report of the visitor and inspector was in the hands of the Council, and so also were the answers of the examiners. It was proposed to postpone the matter, and from experience he judged that to mean until the Greek Kalends. He had the honour of being a visitor, and he had with him the report made on that occasion (1886) by the visitors upon a certain university. He would like to ask the chairman of the business committee what action had been taken by the Council upon the report. It had been shelved. He could not willingly submit to the censure that had been made in the report on the examinations of the University of Dublin. He would not allow that censure to go to the medical world without one word of reply or one expression of opinion of this Council on the merits of the case. They were always very fond in Ireland of speaking of the sense of justice that actuated the English mind, and what he asked for now was fair play.

Sir WILLIAM TURNER said the Council was not in a position to discuss this matter. He would like to put it to Dr. Haughton whether the Council should discuss the report of the inspector and visitor without having before it the answer of the University of Dublin.

Dr. HAUGHTON said the answer was in the Registrar's pocket.

Sir WILLIAM TURNER said his point was that the answer was not in the hands of the Council.

Dr. HAUGHTON promised the Council that it would find the answer very interesting.

Sir WILLIAM TURNER said he had no doubt upon that point, but neither the Council nor the Examination Committee had seen the report. It was a mistake on the part of Mr. Macnamara to speak of the report in question going out to the medical world. The report was a confidential document.

Sir WALTER FOSTER said he had seldom heard a more extraordinary argument than that advanced by Sir William Turner. It was an argument that would be worthy of an official grown grey in the Circumlocution Office. His position was that the Council must not discuss a matter of public interest because, forsooth! the Council had not taken the trouble to look at a document in its possession. It was the fault of the Council if it were not acquainted with the document. He protested against this method of meeting a grave resolution like the one before the Council. He wanted the reports of the inspector and visitor considered by the Council from time to time as they were delivered. If they were to have anything like effective criticism of the reports, they must consider them in detail and not *en masse*. His wish was to have the reports considered *seriatim*, a method of treatment which would be effective and save much valuable time. He hoped that if the Council did not accept the resolution in the exact form proposed it would, at all events, resolve that at the next session this report should be considered, together with any other reports that the inspector had already made.

Sir DYCE DUCKWORTH, as Chairman of the Examination Committee, objected to these reports being constantly in the boiling pot.

Dr. BATTY TUKE moved as an amendment, "That in the opinion of the Council it is inexpedient to take into consideration the reports of the inspector and visitors of examinations until the visitation of the final examination is completed." If each report were considered separately it would lead to great waste of time, for the old battles would be fought over and over again.

Dr. HERON WATSON seconded the amendment, saying that in his opinion it would be wrong on the part of the Council to discuss this particular report until it had the matter fully before it, and especially until it had the report of the Examination Committee.

Dr. ATTHILL thought the amendment raised a question altogether apart from that of the motion.

Sir WILLIAM TURNER proposed as an amendment, "That in the opinion of the Council it is inexpedient to take into consideration the reports of the inspector and visitors of examinations until the report of the Examination Committee on these inspections has been received." He must repudiate the reflection upon his public conduct made by Sir Walter Foster. He would not submit to it without a protest. He wished to ask the Council why an examination committee had been appointed, why the Council had solemnly some years ago appointed an examination committee and an education committee? They were appointed to receive the reports, and, after having carefully considered them and analysed them, to present to the Council what might be described as a fair judgment upon the reports and the answers given by the bodies inspected. It would be entirely out of place for this Council to take up the report upon the University of Dublin or any other examining body, even if the answer were before it, which it was not in this instance, when the Examination Committee had not seen and analysed the report.

Sir WALTER FOSTER said that Sir W. Turner had confused the remarks he made. They were a criticism of his arguments, not of him personally, and he had not drawn the distinction which he thought he might have drawn in the interest of the courtesies of debate.

Mr. BRUDENELL CARTER thought that it would be practically abolishing the Examination Committee if the Council proceeded to discuss this matter without their report.

Sir DYCE DUCKWORTH said that his idea as Chairman of the Examination Committee was that they should not consider the reports piecemeal, but wait until they were all in.

Mr. TEALE moved as a further amendment, "That so many of the reports of the inspector and visitors as shall be in the hands of the Council, with the answers of the bodies affected before the May meeting, along with the reports of the Examination Committee thereupon, be then considered by the Council."

Dr. GLOVER seconded this amendment.

Dr. BATTY TUKE amended his amendment to the following form—viz.: "After the reports of the Examination Committee on the reports of the inspector and visitors of examinations and the answers of the authorities inspected or visited have been laid before the Council, the Examination Committee is requested to report on the inspections from time to time as they are sent in."

Dr. HAUGHTON wound up the discussion with a short reply.

Dr. Batty Tuke's amendment was lost by three votes, while Mr. Teale's was carried.

On Mr. Teale's amendment being put as a substantive motion,

Sir JOHN SIMON expressed doubt as to whether the Council should adopt it without reference to the Examination Committee.

Sir DYCE DUCKWORTH said he would be prepared to bring forward a motion on the subject on the following day.

Dr. MACALISTER, seconded by Mr. BRUDENELL CARTER, moved, "That the reports of the visitor and inspectors of the final examinations, together with any remarks made by the examining bodies thereupon, be referred as they come in to the Examination Committee, and that the committee be requested to report to the Council at the May session on such of the final examinations as have been visited or inspected prior to the end of March, 1893."

Mr. TEALE said he would be happy to accept this motion in place of his own.

The Council took the same view and adopted Dr. Macalister's motion.

*Direct Representatives.*

Sir W. FOSTER moved: "That in the opinion of this Council the number of direct representatives on the General

Medical Council should be increased, in order to give the registered practitioners resident in England and Wales a representation on the Council in proportion to their numbers, as compared with the representation given to the practitioners resident in Scotland and in Ireland." At the outset he asked the Registrar whether he had received from the medical profession or any other bodies interested in this Council any representation in favour of an increase in the direct representatives.

Mr. MILLER said he had received none since the motion was made last year.

Sir W. FOSTER was sorry to hear that, and thought he might attribute it to the attitude of the Council towards his motion when it was rejected last year, and not to any diminution on the part of the profession in the earnestness of their desire to have an increased voice upon the body which governed the affairs of the profession. Since he last moved the motion there had been an election of direct representatives, in which there were certain incidents which he thought were unsatisfactory, and which pointed to a certain amount of apathy on the part of the profession with reference to their representation on the Council. Compared with the previous election there was a grievous falling off in the active interest taken in the election; and that, he thought, was not a healthy state of things. In 1886 74.1 returned their voting papers, whereas in 1891 only 68.3 made the return, and in neither case was the poll as heavy in this educated profession as it would be in any manufacturing or rural constituency for a representative in Parliament. He did not think that was creditable to the profession. Others might draw the inference from this that the medical profession was perfectly satisfied with the present direct representatives, and did not take the trouble to vote for those it had. That, however, was a reflection on the profession which he did not wish to cast. But he did not think it satisfactory that in 1886 25 per cent. of the papers in England and Wales were not returned, and in 1891, 38 per cent. In Ireland 41.5 per cent. were returned, and in Scotland there was no contest. He hoped when future opportunities occurred that the profession would take a much more vivid interest in electing its direct representatives. He had altered the form of his resolution from that of last year, limiting it to England. He placed his argument to-day on the numerical basis, and that basis was the disproportion of the representation of England and Wales as compared with Ireland and Scotland. Taking the Medical Directory he found there were 19,319 practitioners in England and Wales. There were three direct representatives—Dr. Glover, Mr. Wheelhouse and himself—and that gave one representative to every 6528 registered practitioners. On the other hand, he found that Dr. Kidd came there representing 2445 practitioners, and that 2850 practitioners in Scotland had as much power there as 6528 practitioners of England and Wales. He did not say that Scotland or Ireland had too much power; he wanted England to have more power in the Council in proportion to the greater number of practitioners resident in this division of the United Kingdom. If the same proportion were observed in regard to England as to Scotland and Ireland, England would have some eight direct representatives having regard to the Irish representation and seven having regard to that of Scotland. The Act of 1886 empowered them to carry this claim into effect, and if the Council were to make a representation to the Privy Council he had no doubt the latter body would give its sanction to additional representation. If that were not done, the position became difficult. The profession, if they were in earnest about the matter, could raise the question in many ways. They could raise it in the House of Commons and by approaching the Privy Council directly. The Medical Council was now asked to assist to remedy an injustice, and he thought it would be wise, expedient and, on all grounds, morally right and righteous if the Council would recognise the disparity and take steps to remedy it. If they did not, they put themselves in the position of refusing an appeal to their sense of justice.

Mr. WHEELHOUSE seconded the motion.

Mr. TEBALD: Does Sir Walter Foster propose also that there should be an increase in the Crown representatives to represent the public?

Sir W. FOSTER: I have no objection—I am not a Crown member.

Dr. GLOVER said that as this discussion had arisen, and as Sir W. Foster had spoken with very sweet reasonableness on the matter, he begged to support it. The great argument had

been well stated by him—namely, the great disproportion between the direct representation of England and that of Scotland and Ireland. He (Dr. Glover) called on the members of the Council, and that strong sense of justice which they possessed to consider this disproportion and the desirability of remedying it. There was another reason why he thought this proposal was a reasonable one. No observant member of the Council could fail to see that every successive meeting of this Council brought before it a number of questions very deeply affecting medical practice and medical practitioners in this country, especially, he might say, general practitioners. Considering both these reasons, it would be a mere act of justice on the part of the Council to sanction the very modest proposal of Sir W. Foster and so terminate this discussion, which would be a recurring one if not settled, and which would be raised in other quarters.

Sir JOHN SIMON said that not having the honour of being a direct representative, he did not know what the exigencies of that position might be, but if it involved the bringing before this Council of a motion of this character, he did not envy the occupant. He could hardly believe from his experience of the sagacity of Sir W. Foster that he was not quite conscious of the utter fallacy of his argument. His argument rested altogether on a numerical hypothesis. What reason was there to suppose that a numerical hypothesis was contemplated in the constitution of this Council?

Sir W. FOSTER said he explained a third member for England under the Act of 1886 on the ground of the number of practitioners living in that country.

Sir J. SIMON believed that never in the annals of Parliament was a Bill passed under less creditable circumstances than the Medical Act of 1886, and he believed if Sir W. Foster had asked for more he would have got it. He (Sir John Simon) absolutely denied that the numerical principle was recognised in the constitution of this Council. They had suffered disadvantage from their present numbers, and no one could pretend to say that it would be for the advantage of the transaction of their business that their membership should be increased beyond thirty. He could hardly suppose that Sir W. Foster could seriously propose to secure his object by getting rid of Dr. Kidd and Dr. Bruce. The proposal seemed to him quite unreasonable, and he repeated the remonstrance he made last year—that the time of the Council should be taken up with the consideration of the question.

Dr. PETTIGREW did not think that Sir W. Foster had made out any case, and maintained that the numerical idea was utterly absurd.

Dr. WILKS submitted that the numerical basis was entirely wrong, and moved the previous question.

Sir W. FOSTER: That deprives me of my right of reply.

Dr. GLOVER appealed to Dr. Wilks to give way.

Sir W. FOSTER also appealed to Dr. Wilks, who, however, did not give way.

In accordance with the standing order the Council at once voted, when it was decided by 16 to 8 to pass to the next order. At the request of Sir W. Foster the names of the members were taken.

#### *The Punishment of Defaulters.*

Mr. BRYANT had the following notice of motion on the paper:—"That no person who has been removed from the Medical Register by the Council under one of the penal clauses of the Medical Act of 1858, Secs. 28-29, should be restored under two years." He said he had been induced to place it on the minutes because he had felt in common with many members the inconvenience of constant attempts on the part of those who had been removed from the Register to be restored to it after the lapse of only a few months. It seemed to him it was very desirable that they should allow the profession to understand that they looked very seriously upon offences of that kind, and did not mean to trifle with them at all; and that they should for the future let every man feel that there was no possibility of success in appealing to the kind feeling of the Council to be restored before a certain period of time elapsed. It seemed to him, if they were serious in this matter, that two years was not too long a period. He was told by their solicitor that it would not be wise for them to put such a resolution upon their records; but if not, surely there could be no possible objection to their giving some kind of instruction to the Registrar, so that when anyone applied at the office to know whether there was any prospect of his being restored, the Registrar might be empowered to say that not

until the lapse of two years would it be expedient for him to make the attempt. He moved, instead of the motion on the paper, "That it be an instruction to the Registrar that no application on the part of a person who has been removed from the Medical Register by the Council under one of the penal clauses of the Medical Act of 1858, Clauses 28 and 29, be entertained under two years."

The PRESIDENT said the solicitor told him yesterday that the proposal on the paper was one virtually passing sentence before they tried a man. He said there were many different degrees of offence, and he did not think they could pass any such resolution.

Dr. MOORE did not think they should pass such a resolution.

Sir W. FOSTER appealed to Mr. Bryant to withdraw the motion, not, however, because he considered it in any way too severe, but because the Council showed on some occasions, he was sorry to say, a weakness in dealing with these offenders. If Mr. Bryant had said one year he thought it would be eminently judicious, but he thought two years too long.

Dr. BRUCE suggested as an amendment that the limit of the suspension should be until the name had ceased to appear in at least one issue of the Medical Register.

After a brief discussion, in which the general feeling seemed to be against both proposal and amendment,

Mr. BRYANT withdrew his resolution and the subject dropped.

#### *The Restoration of Diplomas.*

Dr. GLOVER moved: "That Mr. Muir Mackenzie's opinion be taken on the following question—viz.: Have the bodies the right to withhold the qualifications of a registered practitioner whose diplomas have been withdrawn from them only on the action of the Medical Council and in cases where the Council has ordered the restoration of the name to the Register? If they have—Has the Council the power to restore the name of a practitioner all of whose qualifications have been withdrawn?"

Mr. TBALE seconded the motion.

Sir WILLIAM TURNER thought it beyond the power of Mr. Muir Mackenzie to answer the second question.

Mr. BRUDENELL CARTER said, with regard to the Society of Apothecaries, that it certainly had the power to withdraw its licence from a licentiate, but it had no power of reinstatement.

Mr. BRYANT explained that the College of Surgeons had this power.

Dr. ATTHILL said the first question, in his opinion, was impracticable. He did not think Mr. Muir Mackenzie would undertake such a task or that the licensing corporations would cooperate with him in what would after all be an inquisitorial inquiry. He moved the omission of the first question.

Dr. HERON WATSON pointed out that the Scotch corporations were not likely to accept the opinion of an English barrister on a matter of this kind.

Dr. GLOVER asked leave to withdraw the first question.

The Council agreed to this.

After some discussion the second question was accepted by the Council in the following form—viz.: "In the event of the name of any practitioner being expunged from the Medical Register by direction of the Council, and of his qualifications being afterwards withdrawn by the examining bodies which granted them, has the Council any power to restore the name to the Register, and if so, under what description as regards qualification?"

#### *The Midwifery Question.*

Sir WILLIAM TURNER moved: "That the Registrar be requested to inform Dr. Rentoul that the certificates referred to in his memorial are neither licences nor diplomas within the meaning of the Medical Acts, and possess no legal value. The Council would also point out that, whilst the certificate granted to women might express that the holder had been trained as a practical midwife, it yet gives no legal qualification to practise." He could not help thinking that Dr. Rentoul failed to appreciate the true position of these certificates. As a matter of fact, they were mere expressions of opinion by certain persons who had taught midwives and examined them. They had no legal value whatsoever.

Mr. WHEELHOUSE seconded the motion. No matter what the wording of the certificates might be, there was a strong feeling among many members of the profession that these people believed themselves to be in the possession of a diploma which enabled them to practise midwifery.

After further discussion, the first part of the motion was agreed to.

The second part was afterwards adopted in the following form—namely: "That the President be requested by the General Medical Council to point out to the institutions and persons who grant such certificates that the certificates should be expressed in such a form as not to lead to the impression that it is a legal qualification to practise midwifery."

#### *"Covering" by Dentists.*

The Council next proceeded to deal with the following draft warning to registered dentists against the employment of unqualified assistants, prepared by the solicitor:—

"Any registered dentist practising for gain who knowingly and willfully deposes a person not registered or qualified to be registered under the Dentists Act, of professionally treating on his behalf in any matter requiring professional discretion or skill any person requiring operations in dentistry of a surgical character, will be liable to be treated as having been guilty of infamous or disgraceful conduct in a professional respect, and to have his name erased from the Dentists' Register."

Sir W. FOSTER moved that the draft warning, which he presumed was in the best legal form, be adopted.

Mr. WHEELHOUSE seconded and the motion was agreed to.

Dr. GLOVER wished to know how this warning was to be put into the hands of the dental profession. They were constantly met in the case of medical offenders by the plea of ignorance. He suggested that a copy of the warning be sent to every person on the Dental Register from this Council.

Sir W. FOSTER said this came before the Executive Committee in consequence of action by the Dental Association, who offered to circulate any warning of this kind among their members. He objected to that course as unworthy of the Council. He did not think they should rely on any private body doing that kind of work for them. He was informed that the method adopted when the warning was issued to the medical profession was to publish the warning in the minutes and advertise it in the medical journals. But they were constantly met by the plea on the part of accused parties that they were not aware of an offence until they were accused. He moved that this warning be issued from the office of the Council to every gentleman whose name appeared on the Dental Register.

Dr. GLOVER seconded the motion. It would not cost much, and then there would be no excuse for ignorance.

Sir W. TURNER thought the dentists would have not the least reason to complain if the course adopted in regard to the medical profession were followed in their case.

The REGISTRAR pointed out that the Dental Association undertook to forward any warning adopted by the Council to the persons on their Register whom it more immediately concerned.

The Council, by 16 votes to 4, adopted Sir W. Foster's motion.

The PRESIDENT: It has been carried that this is to be done from the office here. I confess I think that it is a very great mistake.

The Council adjourned.

## Pharmacology and Therapeutics.

### CARDIO-VASCULAR ACTION OF THEOBROMINE AND CAFFEINE.

Dr. COHNSTEIN, who has been working in Professor von Schröder's laboratory at Heidelberg on the effects of theobromine, caffeine and other similar substances on arterial pressure, confirms the views of Wagner, von Schröder and Binz as to the power of caffeine, or trimethylxanthin as it is chemically named, to raise the blood pressure, this being due to stimulation of the vaso-motor centre. At the same time it exerts a direct influence on the heart, as may be inferred from the alteration observed in the pulse, not merely as to its frequency but as to its hardness and the length of the pulse wave. Theobromine was recommended by von Schröder and Gram as a valuable diuretic, but the clinical observations of Hoffmann, Geisler and others caused this to be disputed, as it was believed by some that the undoubted hydragogue effect of theobromine was the result of direct renal irritation. Others, however, referred the diuresis to the effect on the heart and vessels. Dr. Cohnstein, whose experiments were carried out on dogs and rabbits, is

inclined to conclude that the diuretic effect of the drug is to be traced to a direct stimulation of the kidneys and to consider the improvement in the blood pressure, and therefore of the pulse, as secondary effects resulting from the improvement in the circulation which naturally follows the disappearance of œdema. Other xanthin compounds were studied, but the only one which can be said to have at present any practical interest is œthoxycaffeine, which has been recommended by Dujardin-Beaumez and others in migraine.

#### A NEW REMEDY FOR GONORRHOEA.

Dr. Alejandro Infante, a military medical officer, communicates to the *Revista Médica de Chile* an account of several cases of gonorrhœa and gleet which had proved rebellious to ordinary methods of treatment, but had been rapidly cured by the internal use of the fluid extract of a plant, the *Aplopappus llaeta*, which, like many other species which yield resins, belongs to the division *tubulifera* or *cynarocephala* of the order *Compositæ*. A fluid extract was prepared and this was made into a mixture with water in the proportion of from 2 to 5 per cent. In the chronic cases two or three tablespoonfuls were ordered daily. In a very acute case, where the urethra was almost impervious, a tablespoonful of a 1 per cent. mixture was ordered, at first every hour, and subsequently in less frequent doses of a stronger mixture.

#### TREATMENT OF LUPUS.

Encouraged by the accounts of satisfactory results obtained by Lannelongue, Augagneur, Dubois,<sup>1</sup> and other French surgeons in tuberculous diseases of bone by means of injections of sulphate of zinc, Dr. J. J. Fedoroff of the Borntskovski District Hospital has employed the same treatment for lupus with excellent results. He publishes two cases in the *Vraoh*, No. 27, in both of which the disease was of long standing. His plan was before injecting to shut off the affected locality from the general circulation by compress bandages, and to induce local anæsthesia with cocaine. A 10 per cent. solution of sulphate of zinc was used, about eight minims being introduced at each puncture. From two to four punctures were made around each ulcer, the point of the needle being directed under the base. About the third day the circumference became red and swollen; the next day necrosed tissue appeared on the base of the sore, which came away three or four days later, revealing a healthy granulating surface, and in from a fortnight to three weeks cicatrization was completed. In the cases thus treated there were several sores, and these were not all treated at the same time, it being considered inadvisable to make more than ten punctures at one sitting. None of the ulcers required any renewal of the treatment. If cocaine was not employed a severe burning pain was produced by the injections. With cocaine this was very much lessened. The after treatment consisted simply in a glycerine dressing. There was never any rise of temperature.

#### PROPHYLAXIS AND TREATMENT OF YELLOW FEVER.

Dr. Carlos Finlay of Havana, having in view the experimental researches of several European observers on the possibility of rendering animals insusceptible to the infection of diphtheria and tetanus by means of injections of the blood serum of animals which are naturally insusceptible to these diseases or which have been artificially made so, has proposed to apply a somewhat similar treatment to human beings in order to render them insusceptible to yellow fever, and even to act as a therapeutic measure in cases where this disease has already made its appearance. Of course it must be remembered that yellow fever presents many points of divergence from most other endemic and epidemic diseases. No definite bacteriological cause has been made out, and if there be a microbe it exists in some part of the body not yet determined, and there produces toxins which, being absorbed by the body, set up the disturbance which is characterised by the peculiar symptoms of yellow fever. Again, natives of localities where the disease is endemic enjoy immunity, also those who have resided in such localities for many years, but this immunity is destroyed by a prolonged absence, so that it is probable that whatever it is that confers immunity must be repeatedly introduced into the system. Dr. Finlay suggests that blood serum from acclimatised, that is to say, from insusceptible, persons might be expected to confer immunity if injected in a minute quantity into the system of persons newly arrived in countries where yellow fever prevails, and that probably a much larger quantity might act as a remedy in cases where the attack had already commenced. There

are, of course, in Cuba plenty of insusceptible persons, but it would not be easy to find any who would allow a sufficient quantity of blood to be drawn for the purpose. He therefore proposes to make use of the serum obtained by means of blisters, which is almost identical with that obtained from the blood. He has been able to put this method in practice in only a single case, but in this the results were encouraging; and as the procedure, if carried out with due antiseptic precautions, is perfectly harmless, there is no reason, he thinks, why it should not be given a fair trial. In the case alluded to Dr. Finlay, fearing on the second day that the attack would prove to be one of yellow fever, blistered his own forearm and obtained a few cubic centimetres of serum, which he preserved in sealed tubes. On the fifth day, the symptoms becoming pronounced, he injected half a cubic centimetre of the serum under the patient's shoulder. A very few hours later the nausea and the restlessness passed off and did not return; the temperature, too, sank, though this may have been due to doses of antipyrin. The albuminuria did not cease until the twelfth day, and the icteric tint was present up to the fifteenth; but the patient made a good recovery, the improvement certainly dating from a few hours after the injection of serum. It should be added that there was no soreness or induration at the seat of the puncture. Dr. Finlay's paper, which was read before the Havana Academy of Sciences on Aug. 14th, is published in the *Revista de Ciencias Médicas* of Aug. 20th.

#### THIOL v. ICHTHYOL IN GYNÆCOLOGY.

Dr. Stanislaus Kurtz, writing in the *Kronika Lekarsha*, gives several reasons founded on his own experience for preferring thiol to ichthyol in gynecological practice. The great reason probably why ichthyol has not become better known in this country as a valuable remedy in many skin and gynecological cases is its very disagreeable smell, which it is difficult to cover satisfactorily. Thiol, on the other hand, is odourless. Ichthyol, again, sometimes produces a smarting sensation when introduced into the vagina, from which disagreeable property thiol is free, and indeed it has a tendency to allay pain. Lastly, thiol stains are much more easily removed from linen than are those due to ichthyol. As to the therapeutic uses of thiol Dr. Kurtz has employed it both in hospital and private practice in endometritis after abortion, endocervicitis with erosions and in parametritis. He reports his experience in nineteen cases, in every one of which the results were satisfactory. He used a solution of from 10 to 20 per cent. for applying to the cervical canal either with a probe or by means of tampons impregnated with the solution. Effusions and solid exudations were rapidly resolved by means of thiol tampons in the vagina and these also allayed the pain complained of in the lumbar and pubic regions. In very long standing cases of pelvic exudations Gottschalk of Berlin has very successfully employed thiol tampons simultaneously with inunction of the same substance over the lower part of the abdomen; he also sometimes employs it internally.

#### TRIONAL AS A HYPNOTIC.

According to Dr. Böttiger of Halle trional is a particularly efficient and safe hypnotic. He has employed it in more than seventy cases of a mental and nervous character, and it very rarely produced giddiness, lassitude or any other disagreeable symptoms. Its action was generally manifested in about a quarter of an hour, fifteen grains being often, and thirty grains invariably, sufficient to induce sleep. Where the excitement was but slight the trional succeeded very well in quieting the patient and in inducing sleep, and even in cases of severe mental excitement several doses of fifteen grains each during the day acted so well as a sedative that hyoscine could be dispensed with. The only cases in which trional failed were those in which there was very severe neuralgia or where the mental and motor excitement was extreme, or in alcoholic patients. The drug was given at times by enemata, in the same doses as by the mouth, with equally satisfactory results.

#### MYRRHOLIN.

Dr. Kahn of Würzburg employs a solution of myrrh in an equal quantity of oil, under the name of "myrrholin," together with creosote, in laryngeal and pulmonary phthisis, finding that the myrrholin enables patients to bear the creosote far better than when the latter is given alone. He is not, however, as yet able to say whether the myrrholin exerts any direct action on the disease. He prescribes a mixture of 30 centigrammes of creosote with 20 centigrammes of myrrholin for a dose, to be taken in capsules. A cerate of

<sup>1</sup> Le Mercredi Médical, 18 Mai, 1892

myrrh has also proved very useful in eczema of the nostrils and in atrophic rhinitis, both simple and fetid. Pledgets of cotton wool impregnated with the cerate are passed into the nostril and allowed to remain ten or fifteen minutes.

## ROYAL BRITISH NURSES' ASSOCIATION.

### THE PETITION FOR A CHARTER.

THE Committee of the Privy Council appointed to consider the petition for a charter of incorporation made on behalf of the Royal British Nurses' Association met on Monday at the offices of the Privy Council in Downing-street. The Committee consists of the Marquis of Ripon, Lord Oxenbridge, Lord Hobhouse and Lord Hannen. Sir Horace Davey, Q.C., Mr. Muir Mackenzie, Q.C., and the Hon. W. H. Cross appeared for the petitioners, and Sir Richard Webster and Mr. L. S. Bristowe for the respondents, who are the governing bodies of training schools and hospitals in various parts of the country as well as the Council of the Nightingale Fund.

Sir Horace Davey, stating the case for the petitioners, explained that the Association was a purely charitable organisation. It did not seek profit, nor did it seek any compulsory powers. It was founded five years ago, its great object being to establish a register of nurses founded on the certificates of competency given by the training schools and hospitals. In no sense whatever did it seek to enter into competition with any of these institutions or to control their action. Its great aim was to save the public from being imposed upon by incompetent or inefficient nurses. By inefficient he meant, not only inefficient in skill, but inefficient in point of character. The Association did not pretend to train nurses. It did not pretend to do more than inquire into the competence and character of the persons applying for registration, and to state on the register the result of the inquiry. The registration was, of course, purely voluntary. There was no statutory provision that no one should have the right to call herself a nurse unless her name appeared on the register. The second object of the Association was to afford facilities for nurses exercising thrift and making provision for old age and for those accidents to which nurses were peculiarly exposed. The third object was to afford as much as could be facilities for rest and what might be called recreation. The nurse's life was exposed to great peril of sickness, and periods of rest and recreation were essential, and it was thought that this Association might supply a convalescent home for those who required it. Another object of the Association was to promote meetings, lectures and the like. Since its inauguration five years ago the Association had received a much larger measure of support than even its most sanguine friends expected. His information was to the effect that there were about 2700 nurses upon the register, published yearly by the Association. The importance of this figure would be appreciated when he informed their lordships that there were, according to estimate made, not by his clients, but by others, about 5000 trained nurses in the United Kingdom and about 15,000 women engaged in nursing. Their lordships had also to bear in mind that the Association had had the opposition of some of the principal hospitals and training schools, who had, from their point of view, done all they could to prevent their pupils and nurses entering on the register of the Association. In the circumstances of the case, he thought the Association had good reason to congratulate itself on the large number of nurses on its register. A great deal of the opposition to the Association had proceeded from a misunderstanding of the facts of the case, and he wished to make it clear to their lordships that the Association in no sense undertook to train nurses, but left that work entirely to the useful institutions now carrying it on. The Association desired to act, not in opposition to these institutions, but as supplemental and ancillary to them. It wanted to tell the world what persons held certificates and qualifications from them, leaving the world to judge of their value. One reason for desiring incorporation was the difficulty in obtaining funds. The petitioners had reason to believe that there were charities which would devote funds to such a work as the Association carried on if the latter were incorporated. If the work of the Association were admitted to be useful, then he contended it would be more advantageously and efficiently carried on if the Associa-

tion had the status of an incorporated body rather than that of a voluntary institution which might be dissolved at any moment. The petition, he might say, enjoyed the support of something like 1100 medical men, 1000 nurses and the matrons of hospitals all over the world. The opposition to it proceeded mainly from training schools and hospitals which derived a large part of their income from the out-nurses in their employment. The Association only admitted to its register the names of women who had gone through three years' training, while most of the training schools and hospitals which opposed the petition required a much shorter period of training.

Lord Hobhouse pointed out that there was nothing in the Charter about a three years' course of training.

Sir Horace Davey said that the period of training would be defined in the by-laws of the Association.

Lord Hobhouse.—And of course the by-laws may be altered by the Association.

Sir Horace Davey.—Certainly.

Lord Oxenbridge.—Is the register to be gone through year by year and purged? A good character might in course of time disappear.

Sir Horace Davey replied that this was a matter of some difficulty. All the Association could do was to say that at the time of registration the person registered was capable and reliable. The guarantee of the Association was solely with regard to the period of the training; it had no reference to the character of the training.

Sir Richard Webster then presented the case of the respondents. Before dealing with what he said it may be convenient to state here the reasons drawn up by his clients and presented to their lordships. They were to the following effect:—1. That a general register is not adapted to the calling of nurses for the sick, and that any possible register of nurses would be misleading to the public and detrimental to the interests of nursing. 2. That the proposed register of nurses is in no way analogous to the existing register of medical men, and that the arguments in support of the latter do not apply to the former. 3. That a register of nurses could not be effectually carried on except under statutory powers. 4. That any attempt to maintain such a register under the authority of a Charter would lead to mischievous results. 5. That the grant of a Charter would enable the Royal British Nurses' Association to acquire a real, if indirect, power of controlling the education of the whole nursing profession. 6. That the Royal British Nurses' Association is not a sufficiently representative body, and that it has not secured sufficient support or achieved sufficient success to enable it to be entrusted with such powers. 7. That it has not the means of discharging the duties and responsibilities which the Charter would impose upon it. 8. That the establishment at the present time of any register of nurses would be premature and injurious. 9. That a general register of nurses is unnecessary. That the other objects for which the incorporation is sought can be accomplished without the grant of a Royal Charter.

Sir Richard Webster submitted that if any such powers as those contemplated in the Charter were granted they must be surrounded and safeguarded by provisions analogous to those found in the Medical, Pharmacy, and other Acts. He could not help thinking that there was a good deal of misapprehension about the whole business. It arose from a little forgetfulness of some first principles. This Association could get itself incorporated at once if it simply chose to use the word "limited." It was not a fact that a corporation must carry on trade simply because it used this word. The question for their lordships was whether, the Board of Trade not having thought fit to allow the Association to be incorporated with the omission of the word, the Association should be entitled to incorporation by Royal Charter. He contended that this could not be regarded as a purely optional system of registration. If the Association received this Royal Charter its register would come to be considered by the public as a series of certificates. Every person whose name appeared on the register would be regarded as a person in every way fit and qualified to be upon the register of duly trained and qualified nurses; thus it would become compulsory for a nurse to get admission to the register.

Lord Oxenbridge.—You mean that, in your opinion, if a nurse wants business she must get upon this register?

Sir Richard Webster replied in the affirmative. He contended that the register set forth in the proposed Charter would not lead the public in any way to the source of information from which they could best obtain convenient and

accurate particulars as to what were the qualifications of the nurse.

When the Committee adjourned Sir Richard Webster had not concluded his speech. The Committee will meet again on Monday next.

## CHOLERA.

### CURRENT NOTES, COMMENTS AND CRITICISM.

THERE is no need to say much this week in the way of comment in our chronological record of the progress of epidemic cholera. There have been manifestations of the disease at numerous places widely separated from one another, showing that the cholera cause is extensively distributed, and probably ready to develop itself afresh hereafter on the occurrence of conditions favourable to its manifestations. The disease seems to have obtained a firmer footing in Russia than in other countries. The cholera returns for the past week indicate that the epidemic still prevails there to a serious extent. The reports from St. Petersburg show that in the eighteen districts principally affected there were altogether 3313 cases and 769 deaths, of which the highest figures are from Podolia, Kieff, Bessarabia and Kherson. Apart from these districts, the disease still lingers in fourteen other provinces, where the weekly mortality varies from 10 to 20, while the number of cases is sometimes as high as 50. In St. Petersburg itself the returns for the week were 58 cases and 19 deaths; at Moscow there were 45 cases and 33 deaths; at Warsaw 170 cases and 71 deaths; and at Gitomir 52 cases and 27 deaths. According to a report in *The Times* the Medical Department of the Ministry at St. Petersburg had determined on summoning a council of medical men who had acquired a practical experience of the disease during the present epidemic in that city towards the end of December, with the view of considering the question of the best means of preventing or limiting its spread during the ensuing spring and summer.

Cholera still prevails at Budapest, where there were as many as 10 fresh cases and 5 deaths on the 20th inst.; but these numbers declined to 6 cases and 1 death according to the report of the 22nd from that city. From the Hague we learn that there have been sporadic cases at Utrecht, Breda, Rotterdam and several other places. Last week there were 14 deaths from cholera in the entire country, and there have been 242 since the beginning of the epidemic. There have been several cases of cholera in Brussels, at Bruges and other places. From France we learn that an outbreak occurred at a home for destitute poor at Ville Vaude, in the Seine-et-Marne, where 5 cases occurred. At Dunkirk 6 cases of cholera and 4 deaths were reported at the beginning of the week. *The Temps* publishes a despatch from Lorient to the effect that for the past three weeks choleraic diarrhoea had prevailed there, upwards of 100 cases having occurred, of which about 30 had proved fatal. The disease is specially rife in the suburbs, principally at Kerentrech. The deaths have chiefly occurred among poor, aged or enfeebled people. There have been some cases also in the neighbouring country; at the village of Loomiquelle there were 20 fresh cases on Tuesday last and 4 deaths.

## INTERNATIONAL MEDICAL CONGRESS, ROME, 1893.

THE following is a list of the English committee formed to further the success of the above Congress:—

Sir James Paget, Bart.  
Sir Andrew Clark, Bart.  
Mr. Thomas Bryant.  
Sir Dyce Duckworth.  
Mr. Hutchinson.  
Sir George Humphry.  
Sir W. MacCormac.  
Sir Henry Acland, Bart.  
Professor Clifford Allbutt.  
Sir R. Quain, Bart.  
Mr. J. N. Dick, C.B.  
Sir W. A. Mackinnon, K.C.B.  
Sir J. Fayer, K.C.S.I.  
Dr. Charles Taylor.  
Dr. G. H. Phillipson.

Sir Joseph Lister, Bart.  
Dr. Withers Moore.  
Sir W. Turner.  
Professor Michael Foster.  
Dr. J. Watt Black.  
Mr. H. Power.  
Mr. Shirley Murphy.  
Mr. Gordon Brown.  
Dr. Cheadle.  
Dr. Saundby.  
Dr. Dreschfeld.  
Mr. Mitchell Banks.  
Mr. T. P. Teale.  
Mr. W. F. Favell.  
Dr. E. Long Fox.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6057 births and 3632 deaths were registered during the week ending Nov. 19th. The annual rate of mortality in these towns, which had been 19.6 and 19.5 per 1000 in the preceding two weeks, further declined to 18.6 last week. In London the rate of mortality was 18.4 per 1000, while it averaged 18.7 in the thirty-two provincial towns. The lowest rates in these towns were 12.4 in Halifax, 13.1 in Wolverhampton, 13.3 in Croydon, and 14.1 in Derby; the highest rates were 22.4 in Brighton, 22.5 in Preston, 23.6 in Burnley, 25.1 in Bolton, and 25.7 in Salford. The 3632 deaths included 392 which were referred to the principal zymotic diseases, against 434 in each of the preceding two weeks; of these, 137 resulted from measles, 61 from scarlet fever, 53 from diarrhoea, 51 from whooping-cough, 47 from diphtheria, 39 from "fever" (principally enteric), and 4 from small-pox. No fatal case of any of these diseases occurred last week in Norwich; in the other towns they caused the lowest death-rates in Derby, Wolverhampton, Burnley, and Liverpool, and the highest rates in Croydon, Hull, Brighton and Salford. The greatest mortality from measles occurred in Cardiff, Nottingham, West Ham, Oldham, Hull, Croydon, Brighton and Salford; from scarlet fever in Swansea, Newcastle-on-Tyne and Plymouth; from whooping-cough in Salford and Swansea; from "fever" in Preston, Halifax and Sunderland; and from diarrhoea in Plymouth, Gateshead and Blackburn. The 47 deaths from diphtheria included 29 in London, 3 in Birmingham, 2 in West Ham and 2 in Brighton. Two fatal cases of small-pox were registered in Leeds, one in Sheffield, and one in Leicester, but not one in London or in any other of the thirty-three large towns; 15 cases of this disease were under treatment in the Metropolitan Asylum Hospitals (of which 12 had been admitted during the week) and 2 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 4045, against 4067 and 4063 on the preceding two Saturdays; 404 new cases were admitted during the week, against 462 and 403 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 319 and 357 in the preceding two weeks, declined to 340 last week, and were 80 below the corrected average. The causes of 76, or 2.1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Nottingham, Sunderland, Newcastle-upon-Tyne, and in seven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Blackburn, Preston and Sheffield.

### HEALTH OF SCOTCH TOWNS.

THE annual rate of mortality in the eight Scotch towns, which had been 22.9 and 20.6 per 1000 in the preceding two weeks, rose again to 21.5 during the week ending Nov. 19th, and exceeded by 2.9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17.2 in Dundee and 18.2 in Greenock to 24.1 in Perth and 37.2 in Leith. The 598 deaths in these towns included 65 which were referred to measles, 24 to scarlet fever, 11 to diarrhoea, 11 to "fever," 7 to whooping-cough, 6 to diphtheria, and 3 to small-pox. In all, 127 deaths resulted from these principal zymotic diseases, against 109 and 110 in the preceding two weeks. These 127 deaths were equal to an annual rate of 4.6 per 1000, which exceeded by 2.3 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 69 and 61 in the preceding two weeks, rose again to 65 last week, of which 22 occurred in Edinburgh, 16 in Glasgow, 15 in Leith, and 11 in Aberdeen. The deaths referred to scarlet fever, which had been 13 and 19 in the preceding two weeks, further rose to 24 last week, and included 14 in Glasgow, 4 in Edinburgh, and 4 in Leith. The 11 fatal cases of diarrhoea exceeded those recorded in any recent week, and included 6 in Dundee. The deaths referred to different forms of "fever," which had increased from 2 to 9 in the preceding three weeks, further rose to 11 last week, of which 7 occurred in Glasgow and 2 in Dundee. The fatal cases of diphtheria, which had declined from 12 to 5 in the previous

three weeks, were 6 last week, and included 3 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 142 in each of the preceding two weeks, were 137 last week, and were 177 below the number in the corresponding week of last year, when an epidemic of influenza prevailed. The causes of 57, or nearly 10 per cent., of the deaths in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28.5 and 23.9 per 1000 in the preceding two weeks, was again 23.9 during the week ending Nov. 19th. During the first seven weeks of the current quarter the death-rate in the city averaged 23.2 per 1000, against 17.9 in London and 21.6 in Edinburgh. The 160 deaths in Dublin during the week under notice included 5 which were referred to diarrhoea, 2 to "fever," one to measles, one to whooping-cough, and not one either to small-pox, scarlet fever, or diphtheria. In all, 9 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.3 per 1000, the zymotic death-rate during the same period being 1.7 in London and 5.3 in Edinburgh. The 5 fatal cases of diarrhoea exceeded the number recorded in any recent week. The deaths referred to different forms of "fever," which had been 10 and 5 in the preceding two weeks, further declined to 2 last week. The 160 deaths registered in Dublin last week included 27 of infants under one year of age and 46 of persons aged upwards of sixty years; the deaths, both of infants and of elderly persons, slightly exceeded the numbers recorded in the preceding week. Three inquest cases and 3 deaths from violence were registered; and 54, or more than a third of the deaths, occurred in public institutions. The causes of 19, or nearly 12 per cent., of the deaths in the city last week were not certified.

### THE SERVICES.

The following gentlemen who competed at the examination held on the 7th inst. and following days, at the Examination Hall, Victoria-embankment, for appointment as Surgeon in the Royal Navy have been successful:—

	Marks.		Marks.
Archdale, Henry S. . .	2841	Bunton, C. L. W., M.B.	2446
Clayton, F. H. A., M.B.	2813	Lumley, Fredk. D. . .	2306
Tyffe, Reginald Jas. . .	2052	Meagher, Edwd. Thos.	2302
Lord, Percy, M.B. . .	2577	Tomlinson, Henry E.	2220
Dalton, Fredk. J. A. . .	2515	Bell, Arthur Sydney G.	2318
May, Percival M. . .	2408	Gilpin, Bernard Bevil	2133

#### MOVEMENTS OF MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel Burnett has been posted to Fermoy. Surgeon-Major Smythe has been transferred from the South-Eastern District to Cork, and Surgeon-Major Core from Gravesend to Aldershot. Surgeon-Captain Bond has arrived at St. Lucia and Surgeon-Captain Rawnsley has been transferred thence to Jamaica. Surgeon-Captain Scott has arrived from India on sick leave. Surgeon-Major Drury and Surgeon-Captain Risk have been posted to Aldershot. Surgeon-Captain Harris has been transferred from Devonport to Pembroke Dock and Surgeon-Captain Cocks from the South-Eastern District to Colchester. Surgeon-Colonels Wade and Rudd have been ordered home from India in anticipation of promotion.

The annual examination of Surgeon-Captains for promotion has been fixed for Feb. 6th, 1893.

#### ARMY MEDICAL STAFF.

The following promotions are announced:—Surgeon-Colonel Philip B. Smith, M.D., to Surgeon-Major-General; Brigade-Surgeon-Lieutenant-Colonel Alexander F. Churchill, M.B., to Surgeon-Colonel, vice P. B. Smith, M.D.; Surgeon-Lieutenant-Colonel James Williamson, M.B., F.R.C.S.I., to Brigade-Surgeon-Lieutenant-Colonel, vice A. F. Churchill, M.B.; Surgeon-Lieutenant-Colonel William H. Steele, M.D., F.R.C.S.I., to Brigade-Surgeon-Lieutenant-Colonel, vice J. R. Murray, M.D., F.R.C.S. Edin., retired; Brigade-Surgeon-Lieutenant-Colonel John Ross Murray, M.D., F.R.C.S. Edin., has been placed on retired pay.

#### INDIAN MEDICAL SERVICE.

Surgeon-Lieutenant F. E. Swinton has been brought on the strength of the Bombay Medical Establishment. Surgeon-Captain T. D. C. Barry and Surgeon-Captain L. F. Child

have respectively delivered over and received charge of the duty of Professor of Chemistry in the Elphinstone College. Surgeon-Captain J. T. W. Leslie, M.B., Bengal Establishment, Officiating Chemical Examiner and Professor of Chemistry, Medical College, Calcutta, has been appointed to officiate as Secretary to the Surgeon-General and Sanitary Commissioner with the Government of India until further orders. Surgeon-Major G. S. A. Ranking, M.D., Bengal Establishment, Officiating Secretary to the Board of Examiners, Calcutta, has been appointed to officiate as Chemical Examiner and Professor of Chemistry, Medical College, Calcutta. Surgeon-Major E. L. Maunsell, A.M.S., has been transferred from general duty Poona District, to general duty Scinde District. The following promotions have been approved by Her Majesty:—Bengal Medical Establishment: Brigade-Surgeon-Lieutenant-Colonels: Alfred Swaine Lethbridge, M.D. (dated April 9th, 1892; Arthur Stephen (dated April 16th, 1892); John Henry Newman, M.D. (dated June 1st, 1892.)—Madras Medical Establishment: Surgeon-Lieutenant-Colonel Fredk. Henry Blinkinsop to be Brigade-Surgeon-Lieutenant-Colonel (dated May 23rd, 1892.)—Bombay Medical Establishment: Brigade-Surgeon-Lieutenant-Colonel David Erskine Hughes, M.D. to be Surgeon-Colonel (dated Sept. 15th, 1892); Surgeon-Lieutenant-Colonel Joseph Forbes Keith, M.D., to be Brigade-Surgeon-Lieutenant-Colonel (dated Sept. 15th, 1892). The Queen has also approved of the retirement from the Service of the undermentioned Officers:—Colonel John Barnes Sparks, Indian Staff Corps (dated May 17th, 1892); Surgeon-Colonel John Charles Morice, Bengal Medical Establishment (dated Oct. 24th, 1892).

#### NAVAL MEDICAL SERVICE.

The under-mentioned Staff Surgeons have been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet:—Henry Thompson Cox (dated Nov. 12th, 1892); Richard Gavin Brown, M.B. (dated Nov. 13th, 1892.) The following appointments have been made:—Surgeons: Joseph R. Macdonnell, M.D., additional to the *President*; Arthur S. Nance, to the *Alacrity*; and Jeremiah Sugrue, M.D., to the *Shannon*.

#### VOLUNTEER CORPS.

*Rifle*: The following appointments have been made:—7th Middlesex (London Scottish), Surgeon-Captain J. A. Watson (Honorary Surgeon-Major), from the Volunteer Medical Staff Corps—London Companies Surgeon-Captain; 1st Volunteer Battalion, the Lancashire Fusiliers, Robert Mitchell, M.D., Surgeon-Lieutenant; 3rd Lanarkshire, Surgeon-Major John Dunlop, M.D., Surgeon-Lieutenant-Colonel.

The Volunteer Officers' Decoration has been conferred upon the following officers:—*North British District—Artillery*: 1st Aberdeenshire Artillery Volunteers, Surgeon-Lieutenant-Colonel James Rodger, M.D.; 1st Argyll and Bute Artillery Volunteers, Surgeon-Lieutenant-Colonel William Hunter; 1st Ayrshire and Galloway Artillery Volunteers, Surgeon-Lieutenant-Colonel Robert Blane Erskine, M.D.; 1st Caithness Artillery Volunteers, Surgeon-Lieutenant-Colonel George Banks, M.D.; Surgeon-Major (ranking as Lieutenant-Colonel) T. H. Rutherford, M.D., retired; Surgeon and Honorary Surgeon-Major George Burn, M.D., retired; the Highland Artillery Volunteers, Surgeon-Lieutenant-Colonel Alexander Sclanders, M.D.; 1st Lanarkshire Artillery Volunteers, Surgeon-Major James Simpson Cumming, M.D.; 1st Midlothian Artillery Volunteers, Surgeon-Major (ranking as Lieutenant-Colonel) James Carmichael, M.D., retired; 1st Orkney Artillery Volunteers, Surgeon-Lieutenant-Colonel Wm. Aitchison Wilson, M.D., Surgeon-Lieutenant-Colonel John William Taylor, M.D.—*Mounted Rifles*: Late 1st Roxburgh (Border) Mounted Rifles, Brigade-Surgeon-Lieutenant-Colonel Patrick Kynoch, retired.—*Rifle*: The Queen's Rifle Volunteer Brigade, the Royal Scots (Lothian Regiment), Brigade-Surgeon-Lieutenant-Colonel Sir Douglas MacLagan, Knt., M.D., Surgeon-Lieutenant-Colonel Patrick H. Watson, Surgeon-Major (ranking as Lieutenant-Colonel) Alexander Gordon Miller, retired, Surgeon and Honorary Surgeon-Major Robert James Blair Cunynghame, M.D., retired; 5th Volunteer Battalion, the Royal Scots (Lothian Regiment), Surgeon and Honorary Surgeon-Major John Henderson, M.D., retired; 6th Volunteer Battalion, the Royal Scots (Lothian Regiment), Surgeon-Major Alexander Ballantyne, M.D.; 7th Volunteer Battalion, the Royal Scots (Lothian Regiment), Surgeon-Captain John Liddle Crombie, M.D.; 8th Volunteer Battalion, the Royal Scots (Lothian Regiment), Surgeon-Lieutenant-Colonel Andrew Gilmour; 1st Volunteer Battalion, the Royal Scots Fusiliers, Surgeon-

Lieutenant-Colonel James McAlister; Surgeon-Major (ranking as Lieutenant-Colonel) Archibald Blair, retired; 2nd Volunteer Battalion, the Royal Scots Fusiliers, Surgeon-Major Robert Girvan; Galloway Rifle Volunteer Corps, Surgeon-Lieutenant-Colonel Walter Lorraine, M.D.; 3rd (Dumfries) Volunteer Battalion, the King's Own Scottish Borderers, Surgeon and Honorary Surgeon-Major William Johnstone Carlyle, M.D., retired; 2nd Volunteer Battalion the Cameronians (Scottish Rifles), Surgeon-Lieutenant-Colonel Bruce Goff, M.D., Surgeon-Major (ranking as Lieutenant-Colonel) James London, M.D., retired, Brigade-Surgeon-Lieutenant-Colonel, James, Dunlop, M.D., Surgeon-Lieutenant-Colonel J. Dunlop, M.D.; 2nd (Angus) Volunteer Battalion, the Black Watch (Royal Highlanders), Brigade-Surgeon-Lieutenant-Colonel John Mackie, jun., M.D., Surgeon-Lieutenant-Colonel Wm. Fettes Murray, M.D., Surgeon-Lieutenant-Colonel Jas. Keith Anderson, M.D., Surgeon-Lieutenant-Colonel G. Paton Alexander, Surgeon-Major (ranking as Lieutenant-Colonel) S. Lawrence, M.D., retired; 3rd Volunteer Battalion the Highland Light Infantry, Surgeon-Lieutenant-Colonel John Ewan Brodie, M.D.; 9th Lanarkshire Rifle Volunteer Corps, Surgeon-Lieutenant-Colonel John Lindsay; 5th (Glasgow) Highland Volunteer Battalion the Highland Light Infantry, Surgeon-Major (ranking as Lieutenant-Colonel) Thomas Drysdale Buchanan, M.D., retired; 1st (Ross Highland) Volunteer Battalion Seaforth Highlanders (Rossshire Buffs) (Duke of Albany's), Surgeon-Lieutenant-Colonel Alexander Robertson Mackenzie, M.D.; 1st Volunteer Battalion the Gordon Highlanders, Brigade-Surgeon-Lieutenant-Colonel Angus Fraser, M.D.; 2nd Volunteer Battalion the Gordon Highlanders, Surgeon-Captain William Mortimer; 5th (Deeside Highland) Volunteer Battalion the Gordon Highlanders, Surgeon-Lieutenant-Colonel W. R. Duguid; 1st (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders), Surgeon and Surgeon-Major W. Johnston Marshall, M.D., retired; Surgeon-Major Michael Benny, M.D., Surgeon and Honorary Surgeon-Major William Johnstone, M.D., retired; 5th Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders), Surgeon and Honorary Surgeon-Major John Reid, retired; 1st Dumbartonshire Rifle Volunteer Corps, Surgeon-Lieutenant-Colonel Peter France Robertson, M.D.

#### THE LATE ISAZAI EXPEDITION.

We gather from the *Pioneer Mail* of the 27th ult. that the troops engaged in the late expedition suffered much in health from the great diurnal changes of temperature at the head of the Indus valley. There was a good deal of what popularly goes by the name of "sun fever" among the men of the force, and it is said that some 700 or 800 soldiers are still suffering from mild attacks of continued fever since their return to cantonments.

#### THE FRENCH EXPEDITION IN DAHOMEY.

Since the date of the late sharp engagement, the intelligence of which was received just as we were going to press last week, no accounts of further operations on the part of General Dodds' force have apparently reached the French Government. The troops have now been upwards of two months in the country and, in addition to the injuries resulting from some severe fighting, there has, of course, been much inevitable sickness from malarious fevers and dysentery attributable to the unhealthy climate. As far as can be gathered from the reports that have reached this country the organisation and management of the expedition, military and medical, have so far been very creditable to the French, and General Dodds is recognised as an excellent administrator as well as a good soldier. The account of the unhealthy and debilitated appearance which the 200 invalid soldiers presented on their disembarkation in Marseilles will remind many of the aspect and condition of the men of the Royal Marines on their return from the Gold Coast during the earlier period of the Ashanti War. From the latest information it appears that the fall of the capital has taken place and it is hoped that peace will be concluded by the French upon such terms as will secure in the future a more humane and better state of things in Dahomey.

#### THE EXAMINATION OF CANDIDATES FOR THE ARMY MEDICAL STAFF.

We would call attention to the fact that an examination of candidates for twelve commissions in the Army Medical Staff will be held at the University of London, Burlington-gardens, on Feb. 6th next and following days. Application for admis-

sion to the examination should be made in writing to the Director-General of the Army Medical Department, War Office, London.

#### THE EXAMINATION FOR ADMISSION INTO THE ROYAL MILITARY COLLEGE, SANDHURST.

The parents of candidates for Sandhurst, as well as the candidates themselves, will do well to remember that there are some new regulations in connexion with the medical examination which will come into force on the present occasion. The examination, as we announced last week, will take place on the 28th and 29th instant.

#### FEVER EPIDEMIC IN GUZERAT.

An epidemic of malarial fever attended with great mortality has broken out in the Guzerat district. Intelligence has been received in Bombay from Patan, Radhanpore, Masani, Visnagar, and various other small towns and villages in Guzerat, of the great prevalence of malarial fever. The people are generally in great destitution, and without any medical or nursing aid. The sickness and mortality are stated to be something appalling. In Patan alone forty or fifty persons are dying daily, and it is much the same at other places. The epidemic is the result of a water-logged soil following heavy rains and overflowing rivers. The inhabitants of Guzerat resident in Bombay have held a meeting and raised subscriptions in aid of the sufferers from the epidemic.

#### THE LATE LIEUTENANT HUDDLESTONE, R.E.

At the adjourned inquest on the 21st inst., Dr. Stevenson, analyst to the Home Office, gave evidence to the effect that he agreed with the opinion previously expressed by the local medical men that the death of this officer was attributable to poisoning from decomposition of animal matter contained in tinned sardines. Dr. Stevenson had fed various animals with some of the fish, and inoculated others with matters obtained from the contents of the stomach and from the sardines, with a fatal result to several of the animals experimented on; but he was not able to state exactly what kind of decomposition it was that had caused the fatal poisoning. The decomposition was not likely to have resulted from anything in the solder of the sardine box. The cause of the decomposition of animal matter could not gain access if the boxes were properly tinned and manufactured. The goods supplied to the officers' mess are believed to have been obtained from the Army and Navy Stores, and there does not appear to have been anything about the sardines to have excited attention. The flesh of certain kinds of apparently healthy fish even, especially in the tropical seas, have been known to produce poisonous symptoms, such as gastro-intestinal irritation and severe ataxic nervous symptoms, attended with marked depression. In the case in question, however, the poisonous principle, of the nature of a ptomaine probably, was no doubt the product of some form of decomposition. The jury returned a verdict of "Death by misadventure, caused by eating decomposed sardines."

#### HONOURABLE MENTION OF MEDICAL OFFICERS.

In the official correspondence of the Lushai field operations we are glad to notice the name of Surgeon-Captain J. F. Evans, M.B., 18th Bengal Cavalry. This officer was reported as having shown unremitting care of the sick of all ranks, and as having, by his medical zeal and energy, maintained the health of the corps whilst serving in a notoriously unhealthy part of the world. Surgeon-Captain Evans's services in these respects have been acknowledged by the Government of India and Lord Roberts. Surgeon-Captain Williams and Surgeon-Captain Green, M.S., are names which are also honourably mentioned in despatches relating to operations recently carried out in the Chin Hills and on the north-east frontier of Burmah. Their services have been likewise recognised by the Government of India and the Commander-in-Chief, Lord Roberts.

**EAST LONDON HOSPITAL FOR CHILDREN.**—At the half-yearly Court of Governors of this charity a favourable report was given of the progress of the institution. Its finances had been materially increased, and the new out-patients' room had been completed and is now occupied. To defray the cost of this addition, however, some £2000 is still needed. The formation of a convalescent home is in contemplation, and towards this object a donation of £1000 has already been received.

## Correspondence.

"Audi alteram partem."

## "EXPERIMENTS ON ANIMALS."

To the Editors of THE LANCET

SIRS,—Mr. Lawson Tait asserts that nothing could be more fallacious than to assume that the recent success in intestinal surgery is due to experiments on animals. In support of this assertion he says he has successfully applied the flap-splitting method for the union of the divided intestine for years before the experiments of Senn, Robinson and myself were ever heard of. So successful has his plan been that he has only had one failure in some two or three scores of cases. Upon this assertion it seems strange that his old pupil, Dr. F. Byrom Robinson, should not have adopted Mr. Lawson Tait's method instead of suggesting the use of raw hide and segmented rubber plates. Stranger still that, with such marvellously good results following Mr. Lawson Tait's operation, surgeons at Liverpool, Leeds and London should have introduced the use of decalcified bone tubes and bobbins. Since the time Travers wrote his treatise on "An Enquiry into the Processes of Nature in repairing Injuries of the Intestine," in 1812, until the present day, surgeons have been endeavouring to devise some method of uniting the divided ends of the intestines, and I still maintain that it was not until Senn published the results of his experiences, the direct outcome of experiments on animals, on intestinal anastomoses that any real progress was made or any safe plan of operating on the intestine suggested; and yet now Mr. Lawson Tait tells us that for years before these experiments were heard of he had been in the habit of uniting the divided ends of the intestines by a method than which nothing could be "simpler or more effectual." He scoffs at the clumsy plates, bobbins, &c. This being so, I would ask Mr. Tait why he has not published his plan of operating before? Why has he not shown his cases and demonstrated his method of operating at some one of the medical societies? By doing so, what an amount of time, trouble and vexation he would have saved us poor surgeons who have for years been endeavouring to devise some means of reducing the frightful mortality that has hitherto existed after resection of the intestine—viz., 50 per cent. If he had only done this, should we not all have rushed to the banner of the man who showed such results as Mr. Tait has attained—only one failure in some two or three scores of cases? He does not mention a death, only one failure. If only Mr. Tait had taught us this method, this simple and effectual flap-splitting method, how many lives might have been saved? What a number of poor animals in whom Mr. Tait takes such an interest would have been spared? It is not, however, now too late, and I trust that Mr. Lawson Tait will at an early date see his way to describe fully his method of operating. It would be interesting if Mr. Lawson Tait would tell us in what class of cases he has adopted his operation. Were the resections of the intestine performed for injury to the intestines due to direct violence, or to gangrene of the intestine following strangulation of a loop of gut, or to what causes? Mr. Lawson Tait further says that we now know that the operation of gastro-enterostomy leads to permanent continuous fecal regurgitations, so that the whole scheme of such operations is gradually being dropped. Mr. Lawson Tait may be interested to hear that such is not my experience; neither do I intend to drop the operation, which I am sure is of great benefit, and in many cases life has been considerably prolonged and rendered comfortable.

Mr. Lawson Tait concludes his letter by saying he knows of no operation in intestinal surgery to which he would himself submit other than the operation as performed at present by himself. It behoves Mr. Tait, then, to at once impart to the profession his method of operating, as I can find no mention of it in any of the surgical literature at my disposal, and it would be hard upon Mr. Tait if such a calamity should befall him as to necessitate an operation on his intestines and nobody knew how to perform his special flap-splitting operation.—I am, Sirs, yours faithfully.

FRED. BOWREMAN JESSETT, F.R.C.S. Eng.

Buckingham Palace Mansions, S.W., Oct. 13th, 1892.

To the Editors of THE LANCET.

SIRS,—I am sorry to find Dr. Tyson has also made the fatal mistake of under-estimating the strength of his adversaries. I did not do him the injustice of crediting him with any leaning towards the enemy, but his letter gave me the impression that he had rightly judged the true cause of the strength of the agitation against us. Dr. Tyson cannot be aware that the three greatest writers of our time—Browning, Tennyson and Ruskin, with many names of lesser eminence—have declared themselves strongly opposed to the practice of vivisection, or he would hardly say we have the educated classes almost wholly with us. The medical profession has taken upon itself to justify physiological research by the results obtained. The pure scientists look upon vivisection as a legitimate means of research independent of the results obtained, and theirs is the only ground we can safely take. If the means is not legitimate the end can never make it so; if it is legitimate it needs no justification. I maintain that we have put ourselves in a false position in assuming to shield our brethren from the attacks of an unenlightened public. In this false position lies the strength of our adversaries. A distinguished living F.R.S., himself a physician and a physiologist, speaking to me some ten or twelve years ago of a more distinguished pupil whose leaning was towards pure science, said, "I advised him to take up medicine as a back door to science. Pure science does not pay in this country." I have always thought this to be a prostitution of medicine. Physiological research is as distinct from the practice of medicine as is astronomy from navigation, and any attempt to combine the two will endanger our position in the eyes of the public.

I am, Sirs, yours truly,

WM. F. CLARKE, M.D., B.S. Lond.

Fulham, Nov. 14th, 1892.

## "ABDOMINAL SECTION IN PELVIC PERITONITIS."

To the Editors of THE LANCET.

SIRS,—In your excellent abstract of the adjourned discussion at the Obstetrical Society a misstatement made by one of the speakers is duly reported, but without the correction which immediately followed it.

Mr. Knowsley Thornton called attention to the "extraordinary fact that nearly half" my "operations were incomplete." The context showed that what he meant by "incomplete" was that I had failed to complete the operation that I had intended to perform. I pointed out to Mr. Thornton at the meeting, and I shall be glad if you will allow me to point out to him once more, that when in the summary of my paper I spoke of a certain number of my operations having been "complete" and a certain number "partial" I meant by the word "partial" cases where the disease, and therefore also the operation for its removal were limited to one side. The phrase had no reference to unfinished operations, of which I had happily none to record.

Mr. Thornton also misunderstood that part of my paper which referred to the question of hematocele; and on this subject too I at once, in order to save unnecessary discussion, pointed out where he was in error. I should have dealt with his other criticisms in due course at the close of the discussion, but as Mr. Thornton did not wait to hear my reply I did not feel called upon to make any further reference to his remarks beyond answering a question.

May I also be permitted to correct an error in your report of my reply? On page 1166, column 1, line 22 from top, the words "current year" should be "current half-year," the cases referred to having been published in THE LANCET for July 2nd and 9th, 1892. I am, Sirs, yours faithfully,

Brook-st., W., Nov. 10th, 1892. CHAS. J. CULLINGWORTH.

To the Editors of THE LANCET.

SIRS,—In the discussion at the Obstetrical Society of London on Dr. Cullingworth's paper on Abdominal Section in Certain Cases of Pelvic Peritonitis, several speakers expressed the opinion that inflammatory diseases of the uterine appendages are very rarely the cause of death. Thus Dr. John Williams thought that Dr. Cullingworth's mortality of 18 per cent. was several hundred times greater than that of the disease, and Mr. Knowsley Thornton had never seen a fatal result from perimetritis. The same point is made prominent in your leading article on the discussion, and it is obviously

of the first importance in estimating the advisability of the operation. I had not intended taking part in the discussion, not being a partisan of either side in the controversy. But I should have been tempted to offer a small contribution to the evidence on this subject had I not been prevented from being present at the time. Some years ago, in order to estimate the importance of diseases of the Fallopian tubes, I went through the post-mortem records of Guy's Hospital for the three years 1884-86. I chose those years because at that time the special attention of the pathologists had already been directed to diseases of the tubes, but not many operations for these conditions were yet performed at Guy's Hospital. There were 302 necropsies of women above the age of puberty. Among these were 26 cases, or 8.6 per cent., of inflammatory matting about the uterine appendages, not including any case of tumour or tubercle. There were twelve cases of distended tubes, but only two of pyo-salpinx, and no case of rupture of a distended tube into the peritoneum. Notwithstanding this, there were seven cases, including the two cases of pyo-salpinx, in which the lesion of the tubes appeared to be the primary origin of the fatal disease. No operation had been performed in any of these; and, for the most part, they were not sent down from the gynecological ward, but had been in a medical or surgical ward for peritonitis, abscess or apparent tumour, or for some obscure abdominal disease. The mortality therefore amounts to 26.8 per cent., as compared with the number of cases of chronic adhesions, and 2.3 per cent. as compared with the total number of necropsies. The number of cases is too small to establish a general average of mortality, but I submit that this is positive evidence, as far as it goes, that inflammation of the tubes is not to be despised as a cause of mortality, and that such evidence is of more value than the general impression of a speaker that he has seen many cases of perimetritis and has rarely seen a fatal result follow. Other direct evidence to the same effect from the records of other hospitals has been published. Thus Dr. Kingston Fowler found within three years in the post-mortem room of the Middlesex Hospital fifteen cases of distended tubes, in eight of which the disease of the tubes had been indirectly the cause of death. Dr. Lewers, in 100 necropsies at the London Hospital, found seventeen cases of distension of the tube, in two of which the pelvic condition was the cause of death. In these three groups of cases the mortality of tubal inflammation, compared with the total number of necropsies, appears to be similar, although in Dr. Lewers' cases the relative proportion of tube distension is much greater.

It must be admitted that the cause of death is rarely or never perimetritis alone, but rather general peritonitis, burrowing abscess, or, occasionally, septicæmia or apparent tumour simulating ovarian tumour. In one of the cases of pyo-salpinx referred to above, as found in the post-mortem room of Guy's Hospital, the condition appeared at first sight to be one of double suppurating ovarian tumour. In two cases since that time I have found pyo-salpinx to simulate suppurating ovarian tumour, the patients being evidently in a dying condition from septicæmia. In one of these one tube contained 36 ounces, the other 24 ounces, of fœtid pus. In the other the left tube contained more than 30 ounces of pus and had separated the layers of the broad ligament, burrowing under the sigmoid flexure, its muscular wall hypertrophied to more than half an inch in thickness. The right Fallopian tube was also converted into a pyo-salpinx, but retained its usual anatomical relations. Both these cases ended fatally after operation and go to swell my mortality from operations for diseased tubes. But I think that they furnish an argument, not against such operations, but rather in favour of their being performed before it is too late. If these patients had undergone operation while the pyo-salpinx contained only an ounce or two of pus, and before they had fallen into a septic condition, they would, in all probability, have recovered without serious disturbance. Evidently it is the sequelæ of perimetritis rather than the primary perimetritis which are liable to prove fatal. Thus I have met with one case in which the immediate cause of death was pyo-nephrosis and degeneration of both kidneys caused by pelvic pressure.

I am, Sirs, yours faithfully,

Whmpole-street, Nov. 22nd, 1892. ALFRED L. GALABIN.

## DEATH FROM IRRITATION OF ASCARIDES.

To the Editors of THE LANCET.

SIRS,—Mr. Hillyer, in THE LANCET of Oct. 1st, expresses the opinion that death from the irritation of ascarides is extremely rare. This may be the case at home, but in this

colony round worms not infrequently prove fatal without revealing at the necropsy clear evidence of the way in which death has been produced. On looking through my notes of medico-legal necropsies in cases of sudden death during six years, I find the following record as regards round worms:—In five cases the post-mortem examination showed either no lesions or only such as could be attributed to the presence of worms in the intestine. In two cases round worms were found associated with other conditions, once with malarial fever, and once with pregnancy and dilated heart. In one case death was due to asphyxia caused by a round worm impacted above the epiglottis.<sup>1</sup> The first five cases are those which concern the present inquiry. In one of these a volvulus was discovered in the ascending colon.<sup>2</sup> In another, cerebral effusion was found. This has been mentioned by Eichberg<sup>3</sup> as a result of intestinal worms. In the other three cases, one of which has also been recorded,<sup>4</sup> there was nothing beyond the presence of the round worms to account for death. Besides these cases I have seen four others in which the evidence of death from round worms seemed so clear that I did not consider necropsies necessary. If, then, this is the result of observation in one part of the colony during a limited period, it may fairly be argued that death from this cause is by no means uncommon out here. I understand that a similar frequent mortality obtains in the neighbouring colony of British Guiana. In my experience the cases usually terminate too rapidly for the supervention of congestion or inflammation of the intestine such as is described by Eichberg and others, and I have always regarded the cerebral symptoms as mainly reflex. It is of course conceivable that violent and prolonged convulsions may in some cases produce such conditions as cerebral effusion or volvulus. I am, Sirs, yours truly,

Trinidad, Oct. 31st, 1892.

BEAVEN RAKE.

## CHYLURIA.

To the Editors of THE LANCET.

SIRS,—Dr. Manson's want of success in the treatment of chyluria is no doubt disappointing, though he need not be discouraged in the face of the results of two cases recorded by me in THE LANCET of February 14th, 1891, which are the first examples of chyluria depending on filariæ in the blood I have ever seen permanently cured. The after history of these cases is as follows:—The second patient is at present well, and has had no return of chyluria or of filariæ in the blood. The first patient has also had no return either of the filariæ or of chyluria. But it is an interesting fact that he is now in an advanced stage of tuberculous leprosy, which commenced six months after he had recovered and the thymol treatment was stopped. Possibly there is a connexion between the two diseases. It must be borne in mind, however, that leprosy is endemic in Hyderabad. Dr. Manson's mechanical theory of chyluria is, I believe, hardly tenable. Are we to understand that filariæ possess an affinity for, or the power of selecting, a particular spot in the thoracic duct and there setting up inflammation and a stricture, and that this is the only damage to the system caused by their presence in the blood? To me the invasion and disorganisation of the blood by filariæ are more than sufficient to account for all the phenomena of chyluria described in such an interesting manner by Dr. Manson. Thymol cannot of course cure stricture of the thoracic duct, but it appears to kill the filariæ; and it is never illogical to remove the cause of a disease. In my cases filariæ in the blood were, as far as we could judge, the sole cause of the chyluria. As the filariæ died off under treatment with thymol the chyluria disappeared and has not recurred. A similar result has since been obtained by Dr. Hehir.

I am, Sirs, your obedient servant,

Hyderabad, Deccan, Oct. 30th, 1892.

EDWARD LAWRIE.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Small-pox: Meeting of the Medical Officers of Health Society.

THE epidemic of small-pox cannot yet be said to be abating in the towns of Lancashire and Yorkshire, where its presence has been noted for some weeks past. In Warrington espe-

<sup>1</sup> Brit. Med. Jour., June 11th, 1887, p. 1274.

<sup>2</sup> Ibid., March 24th, 1893, p. 842.

<sup>3</sup> Ibid., Oct. 31st, 1885, p. 842.

<sup>4</sup> Ibid., Jan. 9th, 1890, p. 60.

cially the disease appears to have obtained a firm foothold ; vaccination and revaccination have evidently been neglected for some years past, and so it happens that, the disease having once made headway in the town, abundant pabulum for its wholesale dissemination is at hand in the large proportion of either unvaccinated or imperfectly vaccinated persons. The hospital is stated to be full, and as further accommodation in time to meet the present emergency seems not to be forthcoming, large numbers of the patients have to be treated at their own homes. Under these circumstances it is not surprising that the epidemic still continues to spread. It is reported that within the last fortnight more than a hundred new cases of small-pox have occurred in Warrington. On the 18th inst. an important discussion took place in this city at the monthly meeting of the North-Western Health Officers' Society, on the present prevalence of small-pox. Mr. Vacher, the late able medical officer of health for Birkenhead, who introduced the subject, gave it as his opinion that revaccination and vaccination, as well as notification and isolation, were far more commonly neglected in these parts than was consistent with the public weal. The fact that the Royal Commission on Vaccination had hitherto failed to present their complete report tended, he thought, to convey the erroneous impression to the lay mind that the protection conferred by vaccination was uncertain, and that the whole question, from a medical point of view, was still *sub judice*.

#### *Urmston and Local Government.*

Last week the Parliamentary Committee of the Lancashire County Council had before them the petition of the inhabitants of Urmston for an order of the Council constituting that township an urban sanitary authority. The district of Urmston is mainly a rural one, with a population of about 4000 at the last census and a rateable value of not more than £21,000. The people of Urmston believe that the administration of the district would be greatly improved under a local board, although they adduce no evidence to prove that this would be so ; they appear to have been greatly exercised by the fact that the ratepayers of Urmston have only one representative on the existing authority, and attribute to the negligence of that authority the necessity which has recently arisen for the expenditure by the township of a sum of £3000 for the provision of a cemetery. After a patient hearing, the chairman—who, by the way, is a barrister of experience—announced that the committee could not recommend to the County Council the granting of the petition ; in the first place, because the petitioners had failed to show that they had been otherwise than equitably governed by the existing authority ; and secondly, because there was every likelihood that district councils would shortly be established, and the committee were unwilling to increase the difficulty of the Government in dealing with the whole subject of district councils by establishing a new sanitary authority for a small district like Urmston.

#### *The Health of Manchester.*

According to the last issued return the health of Manchester has been favourable during the three months ending with September last. The gross death-rate did not amount to quite 20 per 1000, a rate which has seldom been achieved in Manchester for so long a period as three months together. The coolness of the autumn has kept in check infantile diarrhoea, which in ordinary years accounts for a considerable fatality in Manchester. Of zymotic diseases, scarlet fever has shown the usual autumnal rise during the quarter, but the disease has not been nearly so prevalent here as in the metropolis. Small-pox has been reported to be present in thirteen instances, the patients having been imported from one or other of the neighbouring towns where the disease has lately been prevalent.

#### *Eccles and Incorporation.*

The local board district of Eccles has recently received a charter of incorporation, and will for the future be governed by a mayor and corporation. Last week the newly elected council met for the first time in the Eccles Town Hall amidst a considerable flourishing of trumpets. The first mayor is a local gentleman who appears to have won his laurels as a member of the local board, and who, if one may judge from the newspaper version of his speech on this occasion, is determined that the new corporation shall not hide its light under a bushel. The first formal business at the meeting was to declare the old local board dissolved. After this the clerk of the board was duly inducted into the office of town clerk, and the various other officers

were appointed. The new corporation will have plenty of work before them for some years to come. The district of Eccles is really a suburb of Manchester, and most of the residents there have their places of business in the city. The health of Eccles, according to the reports of the late local board, has not always been what it might be, and the corporation will do wisely in seeking out and removing any causes of ill health which may exist in this important and rapidly increasing town. The building by-laws of Eccles, like those of many other local boards, might be improved with advantage ; and if the corporation could be induced to replace them entirely by the admirable model code of the Local Government Board, as has been done in Manchester, everybody except the jerry builders would be the gainers. With regard to the question of hospital provision for infectious diseases, the new borough is most fortunately circumstanced ; for instead of being obliged to incur the serious expense of erecting and supporting a separate hospital of their own, they have one on their very boundaries in the splendid new sanatorium recently erected at Ladywell by the Salford Corporation. This institution, as it is one of the most recent, is likewise one of the very best fever hospitals in England ; it contains about 200 beds and abundant space for extension in the event of an epidemic of extraordinary proportions. The disinfecting arrangements at the hospital are of such excellent design and on such an ample scale that the Eccles Corporation will do wisely in endeavouring to arrange with Salford for the isolation of patients and the disinfection of bedding &c. at the Ladywell sanatorium.

Manchester, Nov. 22nd.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

#### *The New Mayor and the Hospitals.*

MR. R. D. HOLT, the newly elected mayor of this city, following the example of his predecessors, paid a visit to the Infirmary for Children on the 13th inst., the first Sunday after his election, and on the following Sunday attended morning service at St. Barnabas Church. Here a sermon was preached by the Rev. Canon Acheson of Chester, and a collection was made for the funds of the Royal Southern Hospital, which amounted to £84. The mayor, with some of the aldermen, city councillors, and members of the congregation, then went to the hospital, which is within a short distance of the church. They were met by members of the committee and medical staff and visited some of the wards.

#### *Small-pox and Vaccination.*

The proximity of Warrington, where small-pox has for weeks past been epidemic, to this city led to fears that the disease might spread here, there being much traffic between the two places. Some few cases of small-pox have occurred here in lodging-houses, but they have been promptly diagnosed and removed to hospital. At the present time the epidemic is said to be subsiding in Warrington. The disease has appeared in St. Helens, and some trouble was experienced in inducing one patient to submit to removal to hospital. Liverpool has its full share of anti-vaccinationists, who have disseminated much mischievous literature among the poor and uneducated. It is also much to be lamented that many vaccinations are performed by the surgeons to cheap dispensaries and that so many practitioners content themselves with two or even one vesicle, to please the children's mothers. It has been calculated that there are in Liverpool at any given time 40,000 unvaccinated persons, including infants under three months. It is therefore most desirable that both vaccination and revaccination should be efficiently performed. A certain proportion of persons are revaccinated, but it is very much smaller than it should be.

#### *The Head Constable's Annual Report.*

The annual report of Captain Nott Bower, the head constable, which has been recently published, deals with the crime of the city and the state of the police establishment for the year ending Sept. 29th, 1892. It is a document which affords many valuable details of interest to medical readers. Among these are the statements that 359 members of the force received rewards for skill in rendering aid to sick and injured persons upon being commended by the surgeons of the various hospitals, while five constables received medals, two silver clasps, and two certificates from the Humane Society for saving life from fire or

drowning. One constable received an illuminated address from the Society for the Protection of Life from Fire, and two constables received—the one a bronze medal and certificate, and the other a certificate, from the Grand Priory of the Order of the Hospital of St. John of Jerusalem in England for gallantry in stopping runaway horses, the presentation in the two latter cases being made by H.R.H. the Prince of Wales. The certificate of the St. John Ambulance Association of qualification to render first aid in cases of sickness or accident is now held by 570 members of the force.

#### *The Police and the Social Evil.*

During the last two years proceedings have been taken against the keepers of all houses which can be proved to be brothels. A total of 727 persons were thus dealt with in the last year, and it is a proof of the terrible persistence of this evil and of the reluctance of the keepers of these houses to betake themselves to some other calling that 131 of these persons had been previously convicted once, 40 twice, 15 thrice and 2 four times. The results of the proceedings were that 76 were imprisoned, 461 were fined, 57 bound over to appear if called upon, 1 committed for trial, 54 absconded, 48 cases dismissed and 23 summonses were withdrawn. While it is satisfactory to state that some of the streets, formerly almost wholly tenanted by this class of persons, have been cleared of them and are more respectably tenanted, it is also to be observed that the evil shows signs of being scattered rather than extinguished. Captain Bower observes that of 19 cases in which summonses were issued against owners or agents of property, in 4 only have convictions followed. This he attributes to the practical impossibility of obtaining such evidence as will prove "knowledge," Section 3, Subsection 3, of the Criminal Law Amendment Act thus proving of little or no avail.

#### *A Year's Inquests.*

During the same year inquests were held upon 957 bodies, and 706 other deaths were reported to the coroner by the police and others, thus making a total of 1663 cases investigated by the coroner during the year. In the 706 cases only informal inquiry was made. Among the inquests were 51 cases of suicide, 338 of accidental death, 161 of infants "suffocated while in bed with their parents," "found drowned" 25, "executed" 1, "died from excessive drinking" 164, "natural causes" 119.

Nov. 22nd.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

#### *Newcastle Hospital Sunday Fund.*

THE success of the Newcastle Hospital Sunday Fund this year is shown by the hon. treasurer's third list, just published, which amounts to a little over £3000 and is an increase of about £100 over the same lists for last year. This cannot but be considered satisfactory by all who take an interest in this valuable fund.

#### *North of England Microscopical Society.*

At the last meeting of the North of England Microscopical Society, held in the Natural History Society's museum in Newcastle, Mr. John Brown gave a most interesting and instructive lecture on various microscopical objects with demonstrations, in the course of which he mentioned the names of many connected with Newcastle and district, such as the Hancocks, Bradys, Alders, Athleys and others who had advanced the study of the microscope and natural history pursuits. He also alluded to the veteran Dr. Embleton, who was the first, about sixty years ago, to bring a microscope of any power to Newcastle.

#### *Trial for Murder at Carlisle.*

At the Carlisle Assizes last week George Bruce was tried for the murder of his wife at Whitehaven in August last. Bruce was a miner, and while digging in his garden his wife went to help him. He struck her on the head with the spade, fracturing her skull and killing her on the spot. Prisoner admitted his guilt, but the medical evidence of Drs. Campbell and Harris showed that he was subject to monomania and delusions, Dr. Harris having in the April before the murder recommended restraint. The judge, in summing up, alluded to the medical evidence and to Dr. Harris's recommendation in April, which was not carried out, and said that anyone who knew the difficulties which medical men had to contend

with would not feel surprised that the prisoner was not locked up then. Actions were frequently brought against doctors, and they knew that no one was so clever as men or women who had been out of their mind. The prisoner was found guilty and ordered to be kept in confinement during Her Majesty's pleasure.

#### *Death of Mr. Charles Arnison, J.P.*

The news of the death last week of Mr. Charles Arnison, surgeon, of Stanhope was received at Newcastle with much regret, where he was well known and highly respected. Mr. Arnison was in his eighty-fourth year and first qualified so far back as 1834. He belonged to a well-known medical family and was a son of Dr. Christopher Arnison of Allendale and Alston, whom he succeeded; but on the death of his brother, Mr. George Arnison, in 1866, he removed to Stanhope, where he practised until a few years ago, when he retired; but he continued to take an interest in local matters, and was a liberal supporter of schools, local benevolent societies, and indeed all charitable organisations in Weardale. For several years he has sat as a magistrate on the Stanhope and Wolsingham benches. He has left a widow and one daughter. The funeral took place on Saturday last, and was largely attended by the Dalesmen and by many members of the profession.

#### *Excise Prosecution of a Medical Man.*

At Norton, near Malton, last Saturday, a case of some importance to the profession was decided at the sessions there. The medical officer of health for the district was prosecuted at the instance of the Excise for keeping a male servant without a licence. He had engaged a lad to look after his pony, but it was contended that he was not liable for tax, as the lad did not sleep on the premises, and also did other work for which he was paid. The Excise officer contended it was a test case, but the bench dismissed the case and ordered costs against the Excise, including fee for defendant's solicitor.

#### *Ambulance Work in South Shields.*

At South Shields, at an ambulance demonstration last week, Surgeon-Major Hutton made presentations to the two policemen who succeeded in restoring to consciousness two boys who were nearly suffocated by gas in a bath room under circumstances mentioned in one of my previous letters.

#### *The Darlington Public Vaccinator and the Royal Commission.*

At a recent meeting of the Darlington Board of Guardians the Public Vaccinator raised the question of the suspension of the Vaccination Act pending the report of the Royal Commission on the Act. He pointed out that this affected his position, as in two successive weeks he had only to vaccinate two persons in the first and one in the last week, and that the successful vaccinations, which were formerly 83 per cent., had fallen to 55 per cent. If vaccinations were not enforced he must ask for an increase of remuneration to compensate for loss. It was stated that at the next meeting a resolution would be moved rescinding the suspension of prosecutions.

A death through lead poisoning took place on Saturday last at the Newcastle Royal Infirmary. The patient was a female, aged seventeen, who had worked at the lead works on the Tyne. She had a fit three days before she died and never regained consciousness.

The Denton Holme Nursing Association, Carlisle, has received the generous gift of £70 a year for ten years to provide an efficient nurse for a poor district in the city of Carlisle.

Newcastle-on-Tyne, Nov. 23rd.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

#### *The Edinburgh University Court.*

At the meeting of this Court last week it was resolved that the fees for the professional examination for the degrees of M.B. and Ch.B. under the new Ordinance of Medicine should be apportioned as follows:—The fee for the first division of the examination to be £6 6s., and that candidates who only appear for two subjects shall pay £3 3s., and an additional £3 3s. when they appear for the other two subjects. The fee for the second division to be £6 6s., and candidates who defer to appear for *Materia Medica* and *Therapeutics* shall pay £4 4s. for the first stage of the examination and £2 2s. for the

second. The fee for the final division is also £6 6s., and candidates who fail to pass either in the whole or in one or more of the subjects in any division of this examination shall pay £1 ls. for each subject in which they have failed before they can be readmitted to examination in that subject.

*The Jubilee Institute of Nurses.*

A supplementary sale of work in connexion with this institute was held in the Nurses' Home, Edinburgh, last week. Lady Helen Munro Ferguson, in opening it, said that the idea of nursing the sick poor in their own homes was one of the great movements of the present time. It completed the great hospital system of the day, and it would be difficult to over-estimate the benefit the Institute had already been to the sick poor.

*Royal Physical Society, Edinburgh.*

The first meeting of this Society was held last week, when Dr. Symington, lecturer on anatomy in the School of Medicine and one of the Vice-presidents of the Society, delivered his valedictory address, taking for his subject the "Cerebral Convulsions of the Primates." He traced the history of our knowledge from the earlier anatomists to the present day, and pointed out the great practical advantages which had followed upon a more intimate knowledge of the surface markings of the brain, and then of the physiology of some of its parts. The lecture was illustrated with drawings and copies of Professor Cunningham's casts of the brains of several of the Primates.

*Health Statistics.*

For last week the returns of notified cases of zymotic diseases were: Measles, 457; scarlet fever, 26; diphtheria, 5; whooping-cough, 3; erysipelas, 9; being a total of 500 cases, a decrease of 59 as compared with the previous week.

*Health of Aberdeen.*

During October there were 213 deaths in the city of Aberdeen, a death-rate of 19.73 per 1000. In September the rate was 16.36, while last October it was 19.25. The mean age at death was 27.1 years. There was a great increase of the mortality among young children, due to the epidemic of measles—1515 cases of measles were reported during the month, as against 307 in September and 63 in August. The mortality, however, only amounted to 2.1 per cent. of the reported cases, which is less than half the usual mortality. The cases of scarlet fever still continue to increase in number, 222 having been reported in October as against 121 in September. Diphtheria was also more prevalent.

*Aberdeen Medico-Chirurgical Society.*

The annual general meeting of this Society was held on Thursday, the 17th inst., when the following were elected office-bearers for the year:—President, Dr. Angus Fraser; vice-president, Professor Stevenson; secretary, Dr. George Edmond; recording secretary, Dr. G. P. Ferdinands; treasurer, Dr. John Gordon; librarian, Dr. G. Rose. Council—Professors Cash and Finlay, Drs. Dalgarno, Rodger and Garden.

*First Meeting.*

At the first meeting of this Society for the winter a presidential address was delivered by Dr. R. J. Garden on "Medical Charities: their Functions and Correlations." Dr. Garden, after mentioning the importance of the subject, referred in detail to the working of the various medical charities in Aberdeen and advocated some changes in their management.

Nov. 16th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Dublin University Biological Association.*

THE opening meeting of the Association will be held on the 24th inst. The President, Dr. Beatty, will deliver an address upon "Functions of the Glands of the Skin." The meeting will be addressed by Dr. Walter Smith, President of the Royal College of Physicians, and Dr. Purser.

*Graduates' Union: Royal University.*

A meeting of the graduates was held last week to discuss a project for the formation of a graduates' union. Mr. Purcell, in moving that the time had arrived for the founding of a Royal University Union, said that such unions were the rule in all residential universities, and their necessity was much greater in the case of a university such as the Royal, where

there were not many opportunities for graduates to meet to take an interest in their University, and to exert a useful influence on its future. The motion was passed, also a resolution to the effect that a provisional committee of graduates be formed to inquire into the prospects of forming a graduates' union.

*Health of Dublin for October.*

As compared with the previous month, there was a considerable decrease in the mortality caused by infectious diseases. The zymotic death-rate, which was 3.77 per 1000 in September, fell to 1.5 in October. There was a slight increase in the fatal cases of scarlet fever; but a great decrease in the mortality ascribed to diarrhoea, probably due to the lowering of temperature, which was 4.2° below the average. As to the general death-rate, it was 1.42 below the average of the corresponding month for the previous ten years.

*Alleged Insanitary Condition of the Hibernian Military School, Phoenix Park.*

It has been stated that the drainage arrangements of this institution, which accommodates some 500 inmates, are in a deplorable condition and that an outbreak of typhoid fever has taken place. As regards the disposal of sewage, the process used is one in which the sewage is mixed with carbolic acid and lime and distributed over an adjoining field. Some of the boys are said to have suffered from a mild form of "gastric" fever, most probably typhoid, and Sir C. Cameron inspected the place on Saturday last and will shortly report on the matter. It must be mentioned that the health of the boys has usually been good and the death-rate exceptionally low.

*Cholera Huts on Kingstown Pier.*

At a recent meeting of the Kingstown Commissioners a communication was received from the Board of Public Works withdrawing their objections to the site on the West Pier for cholera huts, in the event of an outbreak of the epidemic next autumn, upon the following conditions: "(a) That the arrangement is to be a purely temporary one, and to last for one year as a maximum. (b) That the responsibility and risk of erecting a cholera hospital in a place regarded as so unsuitable by the Board rest entirely with the urban sanitary authority. (c) That permission is conditional on the Town Commissioners at once proceeding to exercise their compulsory powers for the acquisition of a site for an isolated hospital, as recommended by the Medical Superintendent Officer of Health, for treatment of infectious diseases, so as to avoid the necessity of having recourse, after the threatened emergency has passed, to the objectionable scheme now contemplated." It appears that the time has passed for this year during which the statutory notices for obtaining land by compulsion should be published; but the Commissioners have promised to do all in their power between this and November next to obtain a site before resorting to compulsion.

*The Ulster Medical Society: Annual Dinner.*

The annual dinner of the Ulster Medical Society was held in Belfast on Nov. 17th, when there was a very large number of members present. The President, Dr. Whittaker, medical officer of health for the city, occupied the chair, and amongst the guests were the Lord Mayor (Sir Daniel Dixon), the President of Queen's College (Dr. Hamilton), Dr. Walton Browne (President of the North of Ireland Branch of the British Medical Association), Surgeon-Colonel Preston, Brigade-Surgeon Howard, Surgeon-Major Bigger, Fleet-Surgeon Wheeler and Professor S. Dill, M.A. After the usual loyal toasts of "The Queen" and "The Prince and Princess of Wales" had been given, the President proposed "The Lord-Lieutenant and Prosperity to Ireland," which was responded to by Professor Whittle, M.D. Dr. M'Keown proposed "The City of Belfast," to which the Lord Mayor replied. "The Queen's College and the Belfast Medical School" was given by Brigade-Surgeon M'Farland, and President Hamilton, D.D., and Mr. John Fagan responded. "The British Medical Association and the North of Ireland Branch" was proposed by Dr. Dempsey and responded to by Dr. Walton Browne and Dr. Byers. Dr. Lindsay gave "Our Guests," and Surgeon-Colonel Preston and Professor S. Dill, M.A., replied. "The Ulster Medical Society" was proposed by President Hamilton, D.D., and Dr. Whittaker (President) and Dr. M'Gaw (secretary) replied. Through the kindness of Dr. M'Gaw, Dr. Mackenzie, Dr. Lindsay, Brigade-Surgeon Howard, Dr. M'Kisack, Dr. Leslie and Dr. Lewers, an admirable programme of music was provided. The dinner, which was one of the largest medical *réunions* ever held in Belfast, was

a decided success, and this was in great measure due to the exertions of the popular secretary of the Society, Dr. M'Gaw.

#### Belfast Royal Hospital.

The annual meeting of the supporters of this charity was held on Monday last, and from the report presented by Dr. Whitla, honorary secretary of the medical staff, I learn that 2455 intern cases were treated during the year ending Aug. 31st, 1892, the largest number ever treated in any year of the hospital's existence. Of these, 998 were medical and 1457 surgical cases. The mortality, excluding the moribund cases in the medical wards, was 5.8 per cent., and 2.7 per cent. in the surgical wards, giving an average mortality of 3.9. In the extern department 20,293 cases were treated during the year. Of these, 5001 were medical and 15,292 surgical. There was an average daily attendance of 180. During the winter session 171 students received clinical instruction, and during the summer 106. A very satisfactory financial statement was presented. The year commenced with a debt of £2203 15s. 6d. The expenditure for the year was £8789 9s. 7d., and the receipts from all sources £15,207 18s. 5d. The receipts, therefore, exceed the debt and expenditure by £4214 13s. 4d., and of this sum £3800 has been invested, leaving a balance of £414 13s. 4d. in the hands of the treasurer. This most satisfactory result is due to some large bequests and to the Centenary Bazaar, which realised £3588 11s. 2d. The receipts from the working men show an increase of £93 7s. 3d. The Chairman of the Board of Management (Mr. W. H. Dixon) said, at the meeting, that it was an open secret in Belfast that the Hospital Committee were endeavouring to acquire the premises of the Belfast Charitable Society for the site of a new hospital. On the previous Saturday the committee of the Charitable Society had come to the conclusion as to the terms on which they would sell to the Hospital Committee, and when it was shown that the people of Belfast were prepared to avail themselves of what was undoubtedly the best site for a hospital in the city, without any detriment to the Charitable Society, the matter would, doubtless, be concluded.

Mr. Charles Lloyd Cowell, L.R.C.S.I., has been elected house surgeon to Monkstown Hospital for six months from Dec. 1st. Nov. 22nd.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### Medical Students v. Town Councillors.

THE Prefect of the Seine and the rest of the venerable City Fathers, sitting in solemn conclave at the Hôtel de Ville on Saturday last, were considerably astonished by the sudden appearance within that stately edifice, at 5 P.M., of an excited crowd of 300 students of the Faculty of Medicine, crying at the top of their voices "Conspuez Strauss!" "Conspuez Peyron!" the gentlemen named being respectively a well-known municipal councillor and the director of the Assistance Publique. Neither M. Strauss nor M. Peyron putting in an appearance, the young people betook them to the Faculty of Medicine, where, in conformity with their request, they were, to the number of 400 or 500, admitted into the large amphitheatre. Two lamps were lit, and Professor Brouardel, the Dean, appeared, and strongly recommended them to keep cool and to refrain from violence, promising to do his utmost to give them satisfaction in the matter in dispute. The assembly then quietly dispersed. What was the cause of the disturbance? It appears that one day recently M. Strauss, with his colleagues of the fifth commission, which exercises supervision over the Paris hospitals, was paying his usual visit to the wards of the Hôpital St. Antoine. In one of the wards, which was only partly filled with patients, they came upon three *externes* in the empty part of the room. Each wore his hat, and one was smoking a cigarette. As they took no notice of the members of the Commission the hospital superintendent, who accompanied them, informed the students of the quality of the visitors. The hats and the cigarette still remaining *in situ*, M. Strauss reproved the young gentlemen, with the result that two of them uncovered, while the third, M. Salmon, continued to smoke and to wear his hat. Result: decree of expulsion issued by M. Peyron against M. Salmon. Common cause was then made with the expelled one by the whole body of students, and it was determined to prevent the holding of the usual competitive examinations for the *externat* and the *internat* unless M. Salmon was restored to his duties. When the students invaded the Hôtel de Ville they had already

successfully obstructed the proceedings at the examination for the *externat*. On Monday last the same tactics were pursued at the examination for the *internat*, which, accordingly, was not held, the examiners retiring. Pouring out of the examination room in the Avenue Victoria into the neighbouring Place de l'Hôtel de Ville they were chased by a squad of police as far as the Place St. Michel, whence they repaired to the Faculty, where they were again addressed by the Dean, who, by the way, is extremely popular. Notwithstanding the announcement that the examinations are postponed until further notice, the manifestations recommenced again yesterday morning at the Assistance Publique and before the Hôtel de Ville, and at the Faculty, where M. Weiss's lecture on Physics had to be abandoned. Meanwhile M. Salmon, on expressing his regret for his conduct, has had his punishment reduced to suspension until Jan. 1st; but this does not satisfy the body of students, who are resolved to support their comrade *à outrance* and also to agitate against municipal interference in the wards of hospitals. They maintain that they are not bound to take any notice of persons other than their chiefs who may visit their wards. As to smoking in the wards, that is a practice that is tolerated, and both patients and *personnel* smoke with impunity out of working hours. I myself have repeatedly seen professors smoke cigarettes at the end of the morning visit. It is also a subject of complaint that the *externes* of all hospitals except remote ones, such as St. Louis, Tenon, Lariboisière, &c., are not paid for their services. Professor Brouardel received on Monday a deputation of *internes* and *externes* of the St. Antoine Hospital. It was understood that a report formulating the demands of the students should be presented to the Dean. At a monster meeting of 1800 students held yesterday at the École Pratique of the Faculty, a petition embodying the following demands was approved: (1) recall of M. Salmon; (2) establishment of a special jurisdiction for the solution of any disputes that may arise amongst the medical *personnel* of the hospitals. Another meeting is fixed for Thursday, in order to determine the advisability of a general strike of *internes* and *externes*.

### Passing of the New Law Regulating the Practice of Medicine.

Some time ago I acquainted the readers of THE LANCET with the principal provisions of the above law. At to-day's sitting the Senate finally adopted it, and it will forthwith come into operation. The only clause not adopted is that dealing with the prohibition of the simultaneous exercise of the profession of medicine and the art of pharmacy. That question will for convenience be dealt with when the new Pharmacy Act is discussed.

Paris, Nov. 23rd.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### Professor Pettenkofer's Experiment.

IN his lecture at the University on the 17th inst. Professor Virchow spoke as follows: "It has repeatedly happened that diseases have been erroneously ascribed to micro-organisms. This was the case with the fermentation fungus, for example, till its harmlessness was demonstrated by experiments on animals. As to the importance of local circumstances emphasised by Pettenkofer, it has been by no means ignored; but local disposition is not the only important thing. From the circumstance that one part of the earth is covered by a pine forest, another by a fir forest, one may indeed infer a special disposition of these parts for the vegetation in question; but these trees flourish in other places too; the main thing is that the bearers of life—germs, seeds and spores—get there. And so it is with cholera and cholera bacilli. These latter are the main thing, and they find in some organisms the conditions most favourable to the engendering of cholera, whereas they pass others by uninjured. The bacilli, therefore, are really the cause of the disease, but they alone do not produce it. They are not the disease itself; on the contrary, the disease consists in the reactions produced by them under favourable circumstances." In an interesting criticism of Professor Pettenkofer's views, addressed to the *Vassische Zeitung* of Berlin, an anonymous medical writer quotes Professor Koch's opinion that more than 50 per cent. of mankind are naturally immune against cholera.

### "Natural Photography."

At last week's meeting of the Berlin Medical Society Dr. Lassar showed life-size photographs of heads. Hitherto

it has been technically impossible to photograph the human face in its natural dimensions. Only the indirect enlargement of objects by means of lenses was practicable. This difficulty has now been got over by Eugen Haak of Stuttgart, who has invented a new way of using the magnesium light. He uses a "lightning cartridge," which gives a very powerful light, extinguishable by means of an electric fuse in the tenth part of a second. This so-called "natural photography" produces impressions of extraordinary accuracy, but requires great skill and practice, and is still very expensive. As yet it is practised by only one photographer in Berlin. Dr. Lassar proved the accuracy of the photographs shown by him by exhibiting the patients from whom they had been taken. Some of the morbid changes were even more recognisable in the photographs than in the patients themselves.

*The Prussian Medical Calendar for 1893.*

The *Prussian Medical Calendar* for 1893, published by Hirschwald of Berlin, with the sanction of the Minister of Ecclesiastical, Educational, and Medical Affairs, does not differ in outward appearance from those of former years. The first part, which contains not only the calendar, but also excellent notices regarding medical apparatus and prescriptions and a diagnostic manual, is by Medical Counsellor Wernich. The second part consists of the official orders that have been issued this year with reference to medical affairs and a list of all the medical men practising their profession in Germany.

Berlin, Nov. 22nd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

*Cholera in Austria-Hungary.*

A BOATMAN who had arrived on a Danube steamer on Nov. 2nd from Raab (Hungary) and who had not left his vessel during his six days' stay, died from cholera sicca on Nov. 8th, without showing any symptoms of sickness even the day before his death; since that date no other case of cholera has occurred in Vienna, and the cholera hospital was closed last week. The total number of cholera cases recorded was four, of which number three died and one recovered, but in two of the cases the clinical symptoms and intestinal pathology differed from those of ordinary cholera Asiatica and the diagnosis of the cases was based merely on the presence of the comma bacillus. In Galicia the cholera has disappeared in the district of Cracow, and the restrictions on the traffic in this province have now been removed. Official statistics show that 865 cases of cholera have been notified to the municipality during the month of October, but 185 cases of these were proved not to have been cholera. The mortality among the remaining 680 cases of real cholera Asiatica was 57 per cent. At the commencement of the epidemic the mortality was extremely high—over 80 per cent. A favourite remedy in some of the hospitals was the internal administration of chloroform, which proved of benefit in some cases in the vomiting. Mustard baths and the internal use of an extract of onions and of allylsulphide were also tried without any significant effect.

*The Microbes of the Danube Water.*

In the Hygienic Institute of the Vienna University the water of the Vienna Danube Canal was examined bacteriologically by Dr. Heider, Professor Gruber's assistant, some weeks ago. He found two species of vibrio-like bacilli, similar in their microscopical appearance to the comma bacillus. One of these bacilli exhibited the same reaction in its cultures as the comma bacillus. The vibrio of Dr. Heider showed clearly, if cultivated in 1 per cent. peptone-water, the cholera-red test acting by reducing litmus-bouillon within twelve hours, and producing a brown pellicle on potatoes, thus rendering it indistinguishable from the growths of the comma bacillus. During the first twenty-four hours the gelatine plates inoculated with Heider's vibrio resembled those inoculated with Koch's comma bacillus. Later on there was a difference to be observed between the vibrio cultures and those of the comma bacillus, the former being darker and the culture mass being more equally distributed throughout the liquefied gelatine. Test-tube cultures of Heider's vibrio differed only in the quicker growth and the more equable and more pronounced opacity in the appearance produced by the comma bacillus.

Vienna, Nov. 20th.

Obituary.

GEORGE ROSS, A.M., M.D.

DR. ROSS, Vice-Dean Faculty of Medicine, McGill University, Montreal, and Professor of Practice of Medicine, died on Nov. 8th, 1892, aged forty-seven. He was well known as a consultant throughout the whole Dominion of Canada, and as a clinical teacher his reputation was unequalled. He was a most acute diagnostician, and his method of teaching was somewhat like that of the late Dr. Murchison. He had been President of the Canadian Medical Association and of the Montreal Medico-Chirurgical Society. Although possessed of excellent literary ability and editor of the *Montreal Medical Journal*, he was not a prolific writer, his contributions consisting chiefly of papers read before the various societies. His article on Aneurysm, written for the "Reference Handbook of the Medical Sciences," has attracted much attention in America. Dr. Ross was a clear and forcible speaker and a very popular lecturer. He will be much missed, and his University will have difficulty in replacing him. No less than three Professors of Medicine have died within the last three years—viz., Drs. Howard, McDonnell and Ross.

ROBERT ZACCHEUS PITTS, M.R.C.S., L.S.A.

By the premature death from typhoid fever on the 9th inst. of Mr. R. Z. Pitts Chelmsford has lost one of its ablest practitioners—one whose character and genial manners had endeared him to every class of the community. Born at Hingham, Norfolk, in 1850, Mr. Pitts received his medical education at the Middlesex Hospital, where he was a most successful student, and in which he held, in 1872-3, the offices of house surgeon and house physician. On leaving London he was appointed house surgeon to the West Herts Infirmary, Hemel Hempstead, a post held by him for about five years, and in this place he made many life-long friends. In June, 1879, Mr. Pitts went to Chelmsford, succeeding to the practice of Dr. Orpen of that town. In spite of his ever-youthful appearance, Robert Pitts made his way in practice with remarkable rapidity. He possessed in an eminent degree all those qualities which are essential to success. Thus, in the first place, he had a great love for his profession; and, in the next, he was never idle. Skilful and full of resource, and notably self-reliant, he was always sympathetic and good-natured, earning the affection of his patients and disarming all rivals. A great lover of natural history and of English literature, Mr. Pitts had for some years occupied his leisure in the study of ornithology, and in collecting specimens and books bearing on the subject. Still, he never had much leisure—for he died in harness—and may have naturally looked forward to a less busy time when he could have devoted more attention to extra-professional pursuits. During his fatal illness he was attended by his partner, Mr. Holland, and by his friend and former fellow-student, Dr. Sidney Coupland, of the Middlesex Hospital. The feeling in Chelmsford at his death found eloquent expression in the sermon preached at Holy Trinity Church by the rector, the Rev. A. Cyril Pearson, in the tributes in the local press, and, above all, in the large and representative gathering at the funeral on the 12th inst. He leaves a widow and five children to mourn their loss, but his family and friends have the consolation that his life, comparatively brief as it was, was spent in the service of his fellows, that it was marked by sterling rectitude, and was, moreover, full of the happiness which comes of the consciousness of work well done.

FRANK GILPIN, M.R.C.S., L.S.A.

AT the early age of twenty-seven and after barely two years' experience of the duties and responsibilities of a professional career Mr. Frank Gilpin, medical officer of health for Stratford-on-Avon and district, died on the 16th inst. from typhoid fever. Mr. Gilpin, who was unmarried, was a former student of the Middlesex Hospital, where he was a general favourite and where his excellence in the cricket and football fields is doubtless known to many outside his own school. He was appointed to the post of medical officer of health at the end of 1890 and soon showed his fitness for the duties pertaining thereto. It has been pointed out that it was owing to his exertions that a fever hospital has been erected at Loxley and that what threatened to be a severe epidemic was averted. During his illness, which was probably contracted in the discharge of his duties, he was attended by Messrs. Nason and Norbury,

as well as by his brother, Mr. R. H. Gilpin of Evesham, and also by Dr. Cayley of the Middlesex Hospital. It is seldom that we have the mournful task of recording the abrupt termination of a career just after it had opened with so much promise.

G. W. RHODES, M.R.C.S., L.S.A.

THE death is announced of an old Huddersfield practitioner—Mr. George W. Rhodes—at his residence, Queen-street South, on the 22nd inst. He was an honorary surgeon of the Huddersfield Infirmary and had been president of the Huddersfield Paxton Society. In all local improvements he took a great interest, especially in educational matters. The deceased gentleman was in his sixty-ninth year.

THOMAS WILTSHIRE, L.R.C.P. EDIN., L.F.P.S. GLAS., &c.

WE announce with regret the death of Mr. Wiltshire of Tunbridge Wells, aged fifty-six. About twenty-eight years ago he succeeded to the practice of Mr. Tinsley, a leading and respected surgeon at Sheffield. By dint of hard work and devotion to his profession he succeeded in retaining one of the largest practices in the north of England until about five years ago, when he retired. He never tried for any medical appointments, nor did he interfere with public affairs. He was simply devoted to his profession as a surgeon. He was well liked by the members of his profession, and was beloved by his patients and friends. During the winter of 1890-91 he suffered severely from an attack of influenza, from which he never completely recovered.

HENRY MOON, M.R.C.S., L.D.S.

WE have to record the death of Mr. Henry Moon, late dental surgeon to Guy's Hospital, at the age of forty-seven. He was born at Tottenham, Middlesex, and was the son of Mr. William Moon, a gentleman in large general practice there. He was for a time educated at Bruce Castle, but, being of delicate constitution, he had private tutors at home, but afterwards went to Germany. On his return he entered at Guy's Hospital, but after he had passed it was considered unwise for him to undertake the rough work of general practice, and he devoted himself to dentistry. In a few years he became Vice-President of the Odontological Society, Examiner in Dental Surgery at the Royal College of Surgeons, England, and dental surgeon to the Dental Hospital, London, and on the retirement of Mr. Salter he was appointed dental surgeon to Guy's Hospital and lecturer on dental surgery. He wrote the article on Dental Surgery in "Bryant's Surgery," besides many papers in the Odontological Reports and in the Journal of the British Dental Association. About four years ago his health began to fail, and after much urging he went to New Zealand, where he improved for a time, when family affairs brought him again to England; but his health again gave way, and he died on Nov. 14th. Of gentle, kindly manner, most conscientious, generous, and thoroughly reliable, it was no wonder to his friends that he succeeded in private practice as rapidly as he did in his public position.

## Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the recent M.B. Examination:—

*First Division*—Christopher Addison, Arthur Seal Blackwell, B.Sc., Wm. Black Jones, H. T. Parker, Walter Ley Pethybridge, B.Sc., and C. E. Wheeler, B.Sc., of St. Bartholomew's Hospital; Louis B. Aldrich-Blake and Mary Ellen Rye, of the London School of Medicine and Royal Free Hospital; Hamilton Ashley Ballance, Arthur Douglas Heath, John Jones, Cecil Benjamin T. Muirgrave, Martin Randall, B.A., Edmond Wallace Selby, Hugh Roubilliac Smith, Chas. George Spencer, Geo. Arbour Stephens, B.Sc., and Frank W. Wesley, of University College; Chesman Barker, of the Sheffield Medical Institution and St. Bartholomew's Hospital; Wm. Bligh, Francis Jordan Coleman, Arthur Mantell Dady, C. Caldwell Elliot, Stephen G. Floyd, Edwd. T. E. Hamilton, B.Sc., C. Satchell Fantin, Arthur John Sharp, and T. Robinson Taylor, B.Sc., of Guy's Hosp.; Chas. Richd. Box, B.Sc., W. P. Purvis, B.Sc., and Seymour Graves Toller, of St. Thomas's Hospital; Albert Edward Brindley and Richard Hamilton, of Owens College and Manch. Royal Infirmary; Thomas Grigor Brodie, Henry Stephen Sandifer, and Arthur Whitfield, of King's College; John Evans, of the Univ. Colleges of Liverpool and London; Jessie Elwitt Hatch, of the London School of Medicine for Women; Vincent Warren Low and Leonard Rogers, of St. Mary's Hospital; J. Saint Johnston, Sidney Herbert Perry and Thos. Major Tibbets, of Queen's College, Birmingham; Wm.

James Procter, of the London Hospital and University College; Frank Allan Roberts, of Yorkshire College; Clement Michael Rogerson, of Yorkshire College and General Infirmary, Leeds. *Second Division*.—Herbert Stanley Ballance and Howard Distin, of King's College; Robert Henry Cole, of St. Mary's Hospital; Henry Wilkes Gibson, of Middlesex Hospital; Charles Joseph Harrison, of University College; Thos. David Lister, of Guy's Hospital; John Williamson Pugh, of London Hospital; Herbert Ramsden, of Owens College; Henry Eugene Tacey, of St. Bartholomew's Hospital; Stephen Longmore B. Wilks, of Yorkshire College.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the subjects indicated:—

*Surgery*.—C. K. Batchellor, Queen's College, Birmingham; W. E. Barker, Owens College, Manchester; S. A. Clarke, Middlesex Hospital; H. E. Cooper, St. Thomas's Hospital; H. S. Elliott and N. Elrington, St. George's Hospital; V. P. Fote, Charing-cross Hospital; W. E. Gibbs, Durham; F. G. Hargrave, London Hospital; C. S. Lewis, St. George's Hospital; O. H. A. Maggs, Charing-cross Hospital; A. Marshall, St. Thomas's Hospital; G. H. Nowell, Cambridge University and Westminster Hospital; M. Richards, London Hospital; E. Smallwood, Liverpool.

*Medicine, Forensic Medicine and Midwifery*.—A. Baldwin, Edinburgh; H. A. Beetham and F. G. Dorey, Yorkshire College, Leeds; E. Herd, Cambridge University and Manchester; Jeaffreson, University College; E. G. G. Little, St. George's Hospital; G. Martyn, King's College; G. H. Nowell, Cambridge University and Westminster Hospital; A. B. S. Stewart, Yorkshire College, Leeds; A. T. Todd-White, Guy's Hospital; G. W. Wickham and S. Wimbush, St. Bartholomew's Hospital.

*Medicine and Forensic Medicine*.—B. E. Church, St. Bartholomew's Hospital.

*Forensic Medicine and Midwifery*.—H. W. Joyce, King's College; H. E. Mortis, Charing-cross Hospital.

*Forensic Medicine*.—F. A. P. Arnold, London Hospital; A. H. Hardcastle, Yorkshire College, Leeds; W. E. S. Jones, Guy's Hospital.

*Midwifery*.—J. E. Bailey, University College; W. Handcock, Yorkshire College, Leeds; J. J. Powell, Cambridge University and St. Thomas's Hospital; A. L. Roper, Cambridge University and Guy's Hospital; J. D. Willis, Owens College, Manchester.

To Messrs. Arnold, Baldwin, Baldwin, Batchellor, Dorey, Elliott, Elrington, Foote, Handcock, Hargrave, Jeaffreson, Lewis, Maggs, Mortis, Nowell, Powell, Richards, Wickham, Willis and Wimbush was granted the diploma of the Society entitling them to practise Medicine, Surgery and Midwifery.

UNIVERSITY OF GLASGOW.—The following gentlemen have passed the Examinations mentioned below:—

*Doctor of Medicine*.—Henry Leslie Graham Leask, M.B., C.M. Scotland; John Rowat, M.B., C.M., Scotland; John Cockburn Syson, M.B., C.M., Scotland.

*Doctor of Medicine (Old Regulations)*.—Daniel M'Neill, L.F.P.S.G., Scotland.

*Bachelors of Medicine and Masters in Surgery*.—James William Moon Buick, England; Robinson Buddock Coyle, Ireland; Adam Guthrie Burrell, William Cassels, Farquhar Gracie, Campbell Hight, Alexander Kelso, William Anderson Kirkwood, William M'Call, Archibald Robertson, M.A., James Andrew Robertson, Alexander Marshall Roy, John Barr Stevens, and Charles Stewart, Scotland; George Nelson Turner, South Seas.

ROYAL COLLEGE OF SURGEONS IN IRELAND: DENTAL EXAMINATION.—The following gentlemen having passed the necessary examination have been admitted Licentiates in Dental Surgery of the College:—

Mr. Ernest Catt (Scarborough) and Mr. Louis Benjamin Eskill (Bath).

MEDICAL DEFENCE UNION (LIMITED).—At a meeting of the Local Committee for London held at the offices of the British Medical Association, 429, Strand, on Tuesday, Nov. 3th, 1892, Dr. Danford Thomas in the chair, the following resolution was proposed by Dr. Fancourt Barnes, seconded by Dr. Masters and carried *nem. con.*: "That in the opinion of this committee the best interests of the Medical Defence Union would be served if the office of president of the Union was held from time to time by a metropolitan member." Dr. S. Sunderland and the secretaries of the Union did not vote. The honorary secretary, Dr. Campbell Pope, was instructed to forward the resolution to the central council.

BEQUESTS AND DONATIONS TO HOSPITALS.—The Corporation of London has granted donations of 100 guineas each to the City Dispensary, to the Royal Sea-bathing Infirmary for Scrofula, Margate, and to the Royal Hospital for Diseases of the Chest, City-road; and 50 guineas each to the Royal Ear Hospital, Soho, and the Gordon Hospital for Fistula, Vauxhall Bridge-road.—Under the will of the late Mr. George E. B. Lousada of Hyde Park-terrace, legacies of £50 each are left to the Hospital for Sick Children, Great Ormond-street, St. Mary's Hospital, University College Hospital, and the Jews' Hospital, Norwood.—The late Mr. William Hodgson of Haxby, near York, bequeathed £1000 to the York County Hospital and £500 to the York County Asylum.—The treasurer of the Royal Portsmouth Hospital has received £250 from "a prominent man of business in the town."—The trustees of the Walsall Cottage Hospital have received £53 from an anonymous donor.

**HOSPITAL SUNDAY FUND.**—The Lord Mayor has received a sum of £100 for the Hospital Sunday Fund as a donation from the late Miss Anderdon.

**PRESENTATION.**—Dr. Charles Kinsman Rawes of Weston-super-Mare has been presented by the members of the Provident Dispensary in that town with a handsome marble clock in appreciation of professional services rendered to them.

**SURGICAL AID SOCIETY.**—The first meeting of the Brighton and Hove Branch of this Society was held on the 21st inst., in the banqueting room of the Royal Pavilion. The Mayor of Brighton (Dr. Ewart) presided and explained the objects contemplated by the formation of the branch as well as the work of the parent society.

**WILTS COUNTY ASYLUM.**—The Wilts County Council has decided to purchase upwards of thirty-three acres of land adjoining the County Asylum for providing additional airing ground for the patients and for sewerage purposes. Application will be made to the Local Government Board for sanction to borrow the necessary sum for the proposed outlay.

**FOOTBALL CASUALTIES.**—During a match, on the 12th inst., at Sandhurst village a player sustained a compound fracture of the leg and also severely injured his foot. He was admitted to the hospital at the Royal Military College.—On the 16th inst., in a match between King's School; Chester, and Grove Park School, Wrexham, a player of the former school fractured his left leg.

**MEDICAL MAGISTRATES.**—Dr. John Brown of Burnley, Dr. Joseph Ewart and Mr. Bernard Roth of Brighton, Drs. George H. Russell and S. Woodcock of Manchester, and Dr. Arthur Garnons Lawrence of Chepstow have been added to the Commission of the Peace for the boroughs of Burnley and Brighton, the city of Manchester, and the county of Monmouth respectively.

**GREAT NORTHERN CENTRAL HOSPITAL.**—It is intended to hold a festival dinner early in next spring in aid of the funds for the completion of the buildings, and H.R.H. the Duke of York has consented to preside on the occasion. The cost of the extensions, with furniture and fittings, will be at least £27,000, towards which sum only £8000 have been promised or received.

**DOMESTIC HYGIENE.**—A series of eight lectures on various subjects connected with domestic hygiene are being undertaken by the Halesowen and District Technical Instruction Committee, and will no doubt be useful in promoting public interest in matters connected with the health and happiness of home life. The lectures will deal with such points as the management of infants, the means of recognising poisons, what articles of diet should be chosen and what avoided, and so forth. The lecturers are Dr. T. B. Young, and Mr. H. C. Darby, and the series of discourses will extend from Nov. 16th to Dec. 8th.

**THE LONDON HORSE.**—At St. James's Hall, on Monday last, a meeting was held for the purpose of considering what means could be taken to improve the condition of the London horse and furthering the unity and wellbeing of all who in any way were connected with horses. Suggestions were made with reference to the establishment of convalescent homes for horses and to the improvement of their food. The question as to whether horse owners and men should be placed under the authority of the County Council was also discussed. A committee has been formed, and the meetings will be continued during the next few months.

## Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors." Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

### EXPERIMENTS ON LIVING ANIMALS.

WE understand that the address delivered by Dr. Wilks on this subject before the Church Congress has been published in pamphlet form, price 3d., and may be obtained from the publisher, Mr. Kolckmann, 2, Langham-place, W.

Mr. S. B. G. McKinney (Nunhead).—What does our correspondent mean when he asks for a scientific division of the body? No reply can be given to such a wide question. An anatomist would reply to it in one form, a physiologist in another, an histologist in a third—all with equal precision.

### "A CURIOUS INCIDENT."

To the Editors of THE LANCET.

SIRS,—Your issue of Oct. 16th, 1892, having only just reached me, I hasten to furnish the information asked for by Mr. J. Elliot Square under the above heading at page 922. I presume he is referring to the case of Lord A—, who was under the care of my old friend, Dr. Mint. I regret to say he ultimately died in great agony after a protracted illness of one month, during the course of which he got rid of one shilling, two sixpences, a threepenny-bit and three bright pennies, none of which were known to have been swallowed. The half-crown was never recovered, as the friends would not hear of a post-mortem examination—a matter for regret, as there is no knowing how many more coins might not have come to light in this extraordinary and unique case of what was most probably a coin-swallowing mania.

I am, Sirs, yours truly,

India, Nov. 4th, 1892.

A. STEWART.

## TOMMY'S DOCTOR.

(With apologies to Rudyard Kipling, whose experience has doubtless taught him that if it is impossible to make a soldier out of a doctor, it is very unlikely that one could ever become a poet.)

I went up for a service club, and thought I rather queer  
That the fighting (?) members plainly said, "We want no doctors  
here."

The beardless subs within the bar they giggled like to die;  
I thought of other times and scenes, and to myself said I:  
"It's Doctor this and Doctor that, and 'Doctor go away';  
But you sometimes sing a different tune when we're serving far  
away—

When we're serving far away, my boys, all serving far away,  
It's quite a different story when we're serving far away."

I went on active service, and came home with a V.C.  
They gave all other officers rank, but they had none for me;  
They called me a "non-combatant," "camp-follower," a "thing";  
But when we were out fighting, the doctor was a king.  
For it's Doctor this and Doctor that, and "Doctor wait outside";  
But it's Doctor "anything you want" when the trooper's on the  
tide—

When the trooper's on the tide, my boys, the troopship's on the tide,  
But it's Doctor anything you want when the transport's on the tide.

Now, though at home you jeer and scoff at soldier doctor men,  
The army knows what we have done for officers and men;  
And it would be more manly to own it to our face,  
That you know the army doctor your cloth does not disgrace.  
For it's Doctor this and Doctor that, and you treat him like a  
brute;

But it's "saviour of his comrades" when the guns begin to shoot.  
It's Doctor here and Doctor there, and "Doctor, bind my wound,"  
Though the doctor like a soldier is dying on the ground

INKERMAN.

Dr. Whitton.—We cannot go into the matter referred to, which has been the subject of a judicial decision.

## WARNING TO PRINCIPALS.

To the Editors of THE LANCET.

SIRS,—Some time ago I advertised in THE LANCET for an unqualified assistant, and selected one with excellent references, particularly as to sobriety. He turned out anything but satisfactory—in short, drank heavily. On enquiry I discovered his referee was his brother-in-law. After leaving me, and before his departure to a good post in the North of England, he was on a drunken "bout," visiting the lowest inns in the place. Lately I had to advertise again for an assistant, and amongst the selected was one who stated he had good references. I wrote for the names of his employers, and, on applying to the only one he gave me, I received by telegram a satisfactory reply. Meanwhile, not being satisfied with one testimonial, I requested him to furnish me with the address of a former principal with whom I might communicate. I then received from him a letter of recommendation purporting to be a copy of one given to him. I enclosed this copy to the doctor supposed to have written the original, and asked if it were a true copy. His reply was that it must be a forgery, as he had never given such a testimonial, and had anything but a high opinion of the assistant in question. I now believe the telegram sent in the first instance to have been also fictitious.

I am, Sirs, yours faithfully,

November, 1892.

PRINCIPAL.

## "A FORM OF DANDRIF."'

To the Editors of THE LANCET.

SIRS,—"Lux" might find the following method of treatment useful in his obstinate case of dandriff. Let the patient twice daily wash well into the roots of the hair a lotion composed of from two to five grains of perchloride of mercury in a saturated alcoholic solution of boracic acid. When this has been dried let her rub in an ointment of sulphur and carbolic acid—say twenty grains of the first and half a drachm of the other to the ounce, using lanoline or lard, or a mixture of both, as an excipient. For cleansing purposes she might use superfatted potash soap. The case is probably one of seborrhœa or seborrhœic eczema of the scalp, and it may possibly have been communicated in the way suggested. The treatment I have indicated I find pretty successful here. I should be glad to hear how "Lux's" case gets on.

I am, Sirs, yours faithfully,

Glasgow, Nov. 22nd, 1892.

DAVID COUPER.

To the Editors of THE LANCET.

SIRS—Replying to the inquiry of "Lux," I beg to be allowed to say that I have had good results in obstinate scurf of the scalp by washing the head in warm water containing about three drachms each of sod. bic. and liq. picis carb. to the quart, and afterwards applying ichtbyol ointment. Tar soap might be a useful addition.

I am, Sirs, yours truly,

Nov. 23rd, 1892.

E. CURTIN.

To the Editors of THE LANCET.

SIRS,—In reply to "Lux," I would suggest his trying a weak sulphur ointment. I have used it of the strength of two drachms to the ounce of vaseline in a most obstinate case of dandriff with complete success.

I am, Sirs, yours faithfully,

Herne Bay, Nov. 23rd, 1892.

E. C. FENOULNET.

## "HISTORY OF QUACKS AND QUACKERY."

Dr. J. Harold Bailey (Birkenhead) writes:—"Your correspondent might consult 'Sir Thomas Browne's Works, including his Life and Correspondence' (London: William Pickering, 1886), vol. i., page 244:—

'Sir Thomas Browne to his son Edward.

May 28th, 1670.

..... I sawe a woman of 80 yeares, while the cataract was couched in both eyes, and shee had a dimme sight for a yeare after, till shee dyed; it was done by Vanderlas. The ignorance of chirurgeons, as to chirurgeall operations, creates so many mountebank and stage quacksalvers. Heere (Norwich, J. H. B.) hath been a mountebank these 2 months, who cutts for wrye necks, coucheth cataracts, cures hare lipps &c., wherin no chirurgeon of this place being versed, hee hath had a great deal of employment to the shame of our chirurgeons.—Your loving father,

THOMAS BROWNE.

'These for Dr. Edward Browne, in Salisbury Court, next the Golden Balls, London.'

In 'The Starling,' a novel by the Rev. Normal Macleod, there is an account of the doings of a quack in a country district of Scotland."

Mr. O. B. Shelswell.—The institution referred to is probably the National Society for the Employment of Epileptics. It is situated at Godalming, and its hon. secretary is Miss Burdon-Sanderson, Branksome, Greenhill-road, N.W.

Mr. H. S. Reynolds.—The reply to the question depends on the nature of the actual contract, but we think it would be unreasonable to refuse our correspondent a perusal of the books.

## "OFFICIAL" OR "OFFICINAL"?

To the Editors of THE LANCET.

SIRS,—The terms "official" and "officinal" are frequently used as synonymous by authors of works on materia medica and kindred subjects. The examiners for the triple qualification at Edinburgh fall into the same error; so it may be as well to point out that there is a wide difference between the words. "Official" (*officium*—an office) means issued or sanctioned by authority; "officinal" (*officina*—a shop) means kept in a shop. Blue pill is official; liver pills are officinal.

I am, Sirs, yours faithfully,

Mount-place, E., Nov. 19th, 1892.

ARTHUR H. DOBSON.

## EMPLOYMENT OF COCAINE.

To the Editors of THE LANCET.

SIRS,—Can any of your readers who have used cocaine in minor surgery give me a hint as to the dose and best method of application in a case of fissure of the anus? I should also like to know if it is dangerous to use in the case of purulent ophthalmia of infants or in conjunctivitis of children to allay spasm in the use of astringent lotions.

I am, Sirs, yours truly,

Nov 22nd, 1892.

YOUNG PRACTITIONER.

## CHLOROFORM INHALATION IN PHTHISIS PULMONALIS.

To the Editors of THE LANCET.

SIRS,—I am anxious to know if any of your numerous readers have observed beneficial effects follow the inhalation of chloroform for operations in phtisical cases.

I am, Sirs, yours faithfully,

St. Leonards-on-Sea, Nov. 18th, 1892.

SAMUEL LEE, M.D.

ERRATUM.—In our article on "Municipal Honours and Medical Men" (page 1180) an error occurs in connexion with the name of Mr. George-Wright Hutchinson, who should have been described as M.B. & C.M. Aber. (not M.D.); whilst the clerical office spoken of as having been formerly held by him was not held by him, but by his father.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &amp;c., have been received from—

A.—Dr. F. P. Atkinson, Surbiton; Mr. J. Anderson, Ancoats; Mr. Archer, Alnwick; Mr. H. F. Aveling, London; Messrs. Allen and Hanburys, London; Messrs. R. Anderson and Co., London; A., London; Africanus; Alpha, Lee; Anderson's Medical College, Glasgow; Alpha.

B.—Dr. Robt. Boxall, London; Mr. B. Brown, Huddersfield; Mr. A. E. Barrett, London; Mr. J. Beard, Edinburgh; Mr. Breeze, London; Mr. J. H. Bailey, Birkenhead; Mr. Burgess, Manchester; Mr. W. Botwood, Ipswich; Mr. Peyton T. B. Beale, London; Messrs. Burroughs, Wellcome and Co., London.

C.—Dr. C. J. Cullingworth, London; Dr. Duncan S. Caddy, Earl's Court; Dr. Arthur H. Cheate, Vienna; Dr. Chas. H. Cattle, Nottingham; Mr. T. P. Cowen, London; Mr. T. Clark, London; Mr. J. B. Crozier, London; Mr. E. S. Cockell, West Hartlepool; Mr. Clark, Wolverhampton; Messrs. Cassell and Co., London; Messrs. Cleave and Son, Devon; Celsus, London.

Lectures  
ON THE  
PHYSIOLOGY AND PATHOLOGY OF  
BLOOD DESTRUCTION.

Delivered in the Examination Hall, Victoria Embankment,  
on Nov. 22nd, 1892,

By WILLIAM HUNTER, M.D. EDIN.,  
M.R.C.P. LOND. &c.,

ASSISTANT PHYSICIAN TO THE LONDON FEVER HOSPITAL; LATE  
SANITARY RESEARCH SCHOLAR, GROCERS' COMPANY.

LECTURE I.—(Concluded.)

THE SPLEEN.

THE spleen organ in which blood pigment (independently of extravasation or congestion) is to be found is the spleen.

*In Health.*—I show now sections from the spleen of normal rabbits, and I ask you to note how very little pigment is present. Scarcely a trace of the iron reaction can be developed in them. This is the case with the spleens of young healthy mammals generally. The amount of pigment they contain is, according to my observations, exceedingly small. In birds, as you will see from the sections I now show you from the pigeon and duck, it is present in much larger amount. As age advances it tends to increase. The spleen in dogs, rabbits, guinea-pigs, either aged or kept long in confinement, I have usually found to contain a considerable, sometimes a large, amount of pigment. The pigment lies in the pulp of the spleen, and is contained within its cells. It is present in various forms, partly as large granules, partly as smaller granules, and partly diffused, apparently in soluble form, throughout the substance of the cell. The large splenic cells are its chief seat; in certain cases they may be seen packed full with it.

*In Disease.*—Few organs of the body—not even the liver—present, it might be supposed, such favourable conditions for accumulation of pigment as the spleen; and it might naturally be thought that disease would furnish many examples where the amount would be greatly increased. Such is not the case, however, so far as my observations go—and I have examined the spleen in almost every kind of disease in this special relation. On the contrary, apart from old age or prolonged inanition, and not even excluding them, I know of hardly any condition—an exception being malaria—in which any accumulation of pigment at all comparable with that I have shown you, for example, in the case of the liver in pernicious anæmia, is ever to be found in the spleen. Such an increase, however, may be induced experimentally. (Experiments 1 to 16.) I show you now sections of spleens after transfusion of blood in rabbits, and ask you to note the very great abundance of pigment present—so much so that the whole appearance of the pulp in which it lies is transformed. Although seldom so great or striking as that induced by transfusion, a large increase in the pigment of the spleen may also, I find, be induced by other experimental means. I show you now sections from the spleens of the dog (Experiment 63) and rabbit (Experiment 75), in which you will note a very great increase of pigment induced by injection of toluyldiamine and pyrogallie acid respectively. The pigment in both cases is altogether more diffuse and less particulate in its form than that seen after transfusion. In the fresh tissue the pigment was seen (Experiment 63) to be diffused amidst the protoplasm of the cell, or to be in exceedingly minute granules of perfectly spherical form. Larger granules or globules were very few in number. The same was the case in Experiment 75—most of the pigment was in diffuse form. After transfusion, on the other hand, a very large proportion of the pigment is in the form of large clumps and conglomerate heaps, as may well be seen in the sections I now show you.

1. The amount of blood pigment to be found in the spleen in health varies, within very wide limits, even in animals of the same class. It is usually more abundant in birds than in mammals. 2. Age more than any other factor influences its amount. It is most abundant in the spleens of aged animals.

No. 3614.

3. The variations that occur in disease are less striking and less marked than is the case in the liver.

RED BONE MARROW.

A third seat in which a certain amount of pigment is usually found in health is the red bone marrow. The pigment is in the form of minute granules lying within the marrow cells. Its chemical characters are indefinite. In health it frequently fails to give any reaction of free iron when tested. The fresh marrow gives scarcely any reaction with sulphide of ammonium—at most a light greenish stain.

The conditions that favour the presence of pigment in this situation are, I find, much the same as in the case of the spleen. It is increased in old age; in old animals, especially in dogs, I have sometimes found it present in very considerable quantity. Such increase is always associated with an increase in the pigment of the spleen. The relation between the marrow and the spleen in this connexion is much closer than between the liver and spleen.

KIDNEY.

The liver, spleen, and red bone marrow are the three situations in which, as I have said, blood pigment may be found in varying quantity in conditions of health and disease, independently altogether of extravasation or congestion. There is one other organ, however, in which, according to my observations, such pigment may also be found; not, however, in health, but only in disease, and that only rarely. That organ is the kidney. I do not here refer to the presence of hæmoglobin or hæmoglobin casts such as we naturally find in the kidney—for example, in paroxysmal hæmoglobinuria. I refer to blood pigment proper, partly granular, partly diffuse form, occupying a definite situation—namely, the cells of the convoluted tubules. I show you now a section of kidney from a case of disease in which you will note the peculiar characters and situation of this pigment, also its great abundance. The granules are uniformly small in size and resemble in character those present in the liver cells in the same disease—namely, pernicious anæmia. The further characters of this pigment and the conditions under which it is met I have fully described in my paper "On the Excretion of Blood Pigment in Pernicious Anæmia."<sup>1</sup>

BLOOD PIGMENT AS AN EVIDENCE OF HÆMOLYSIS.

What interpretation are we to put upon the facts just recorded? I have dwelt at some little length on the subject, noting particularly in the case of the liver the results of my observations with regard to the precise situation of the pigment, the differences in its microscopic characters under different circumstances, and the conditions under which it appears in one or other situation. I have done so purposely, for it was by a study of these various points I was led to certain conclusions of some importance regarding the significance to be attached to blood pigment as an indication of a destruction of blood.

It has been usual to hold that the presence of blood pigment (always of course apart from extravasation or congestion) in such organs as the liver or spleen is not only an indication of some previous destruction of blood, but also that its amount indicates the extent of that destruction. Other things being equal, the larger the amount, so it has been held, the greater necessarily the previous destruction. Such was the view I held at the outset of my investigation. One result of the foregoing study was to make clear to me, as I shall now endeavour to make clear to you, that this is very far indeed from being the case. On the contrary, the significance attachable, in my opinion, to blood pigment as an index of hæmolytic varies very much under different circumstances. Its presence may denote not a larger, but, on the contrary, a lessened destruction; while conversely its absence is not only compatible with, but may indeed point to an increased destruction. If our consideration were limited to the case of mammals in health it might almost be said that the amount of blood destruction is frequently inversely proportional to the amount of blood pigment present in such an organ, for example, as the spleen. What significance it has indeed depends far less on its amount than on its character and situation, affording as these latter do important and reliable indications as to the nature of the preceding changes in the blood. Consideration of mere amount alone, apart from its character and situation, may lead to entirely erroneous conclusions regarding the extent of these destructive changes.

<sup>1</sup> Practitioner, 1888.

## ACTIVE AND PASSIVE DESTRUCTION OF RED CORPUSCLES.

From a study, then, of the character and distribution of blood pigment under different circumstances of health and disease I have been led to distinguish sharply two different processes in the blood, each of which may lead to a formation of blood pigment, and each marked by different changes in the red corpuscles.

The first of these is marked by a gradual decay of the red corpuscles. Retaining their form and their hæmoglobin to the last, they are ultimately taken up bodily by the active cells of the spleen or leucocytes of the blood and are stored up within the spleen or in the capillaries of the liver. Within these cells their hæmoglobin becomes transformed into blood pigment, and the pigment so formed is characterised generally by the varying size of its granules and by the largeness of at least some of them, corresponding in size, as they may do, to that of the original red corpuscle. It is this process that leads to the formation of the larger particles and clumps of pigment I have shown you in the capillaries of the liver in frogs, birds, and mammals; and also in the spleen of old mammals and after transfusion. The particular point to be noted about this process is that the whole of the hæmoglobin of the corpuscle is converted into blood pigment and that the pigment so formed is never found within the liver cell. The conditions favourable to such a mode of death of the red corpuscle are for the most part negative. They are such as old age, abstinence from food, want of exercise—such, in fact, as necessarily imply a relative inactivity of the cells of the body, and therefore presumably a relative absence of any great changes in the other constituents of the blood—namely, the plasma and leucocytes. This change in the corpuscle implies an absence of any influences in the plasma of the blood likely to affect the red corpuscles injuriously. The rôle of the plasma and leucocytes in bringing it about is a purely passive one, and hence this mode of death of the red corpuscle may, as I have suggested, conveniently be described as a passive destruction of red corpuscles viewed in relation to the rôle taken in it by the blood as a whole, or *chronic* viewed in relation to its slowness.

The second process is marked by a different series of phenomena. The first of these is a liberation of the hæmoglobin of the corpuscle. It is set free into the plasma and may, as in the other case, likewise be taken up by cells of spleen or leucocytes of blood. If so, it is also converted into blood pigment; but this pigment can, as I have shown you, be distinguished broadly by certain features from that arising from passive destruction—viz., by the smaller and more uniform size of its individual granules. The usual fate of the hæmoglobin thus set free into the plasma is not, however, to be thus taken up by ordinary cells, but to be carried to the liver and to undergo within the liver cells a series of changes differing in detail and in results from those that take place in ordinary cells. The chief result is a formation of bile pigments, not of blood pigment. A formation of blood pigment does not necessarily, in my opinion, attend the breaking up of hæmoglobin by the liver cell in mammals. It is in this respect that this process *qua* the formation of blood pigment differs most materially from that of passive destruction. In the latter the whole of the hæmoglobin is thus transformed; in this process, on the other hand, none of it may be thus converted. This manner of disposal of hæmoglobin is not, as I have said, necessarily attended by a formation of blood pigment. If, however, it does occur, as it undoubtedly does both in health (birds and mammals) and still more markedly in disease (pernicious anaemia, action of poisons), only a part of the hæmoglobin molecule is converted into blood pigment, and the pigment so arising is distinguished by the features already described—namely, the small and uniform size of its granules. It is only pigment so formed that is found within the liver cell.

Such a liberation of hæmoglobin from the red corpuscles implies obviously certain conditions of plasma unfavourable to their preservation—in health, e.g., digestion, and in disease the action of poisons. The important point to recognise is that the liberation of hæmoglobin from the red corpuscle implies as surely the existence of changes in the plasma unfavourable to the red corpuscle as the gradual decay of the red corpuscle implies the reverse. The rôle of the plasma (and by implication also the leucocytes and other cells which control the constitution of the plasma) is thus as active as in the latter case it was passive, and hence, as I have suggested, this form of the destruction of the red corpuscle may conveniently be described as an *active* destruction of red

corpuscles viewed in relation to the rôle of the blood as a whole, or *acute* viewed in relation to its rapidity.

The foregoing expresses, then, the views I have formed regarding the two ways in which blood pigment arises. We are thus led to recognise that two diametrically opposed processes in the blood may lead to its formation, one of them the result of inactivity on the part of, the plasma and leucocytes of the blood (passive destruction), the other as definitely marking the activity of these elements (active destruction). Since the object of our study is to ascertain what it is that affects the blood as a whole, and not any one particular element of it, it will, I think, be clear that the process which brings about what I have termed "active" destruction of the red corpuscles is the only one that is rightly entitled to be spoken of as hæmolysis, since it alone affects the blood as a whole. For, as I have shown, the process termed "passive" is unattended by change in the blood generally—marks, indeed, the absence of such change. It is the changes connected, then, with active destruction of red corpuscles that especially deserve our consideration. It will be now clear to you what a varying significance amount of blood pigment, apart from its character and situation, may have as an indication of hæmolysis; for it is passive destruction of red corpuscles that leads to the conversion of the whole of the hæmoglobin into blood-pigment and its storage up in the body in this permanent form; while active destruction, on the other hand, by causing its liberation into the plasma, favours its disposal and its removal from the body in ways—namely, by action of the liver cells—that are not necessarily attended by any formation of blood pigment at all.

The conclusion, then, is that hæmolysis may be unattended by the formation of any blood pigment, and hence it follows that the absence of such pigment in health in young mammals is quite compatible, as I will now show, with the occurrence of a very considerable daily hæmolysis.

Having thus made clear to you that the evidence to be derived from a study (1) of bile pigment and (2) of blood pigment both alike point to a certain destruction of hæmoglobin, and presumably therefore of blood, as an event of no uncommon occurrence, the question arises: What is the frequency or extent of this destruction in health?

Hitherto our knowledge on this point has amounted to this—that there is a close genetic relationship between certain pigments daily excreted from the body in the urine and bile and hæmoglobin; that blood pigment obviously derived from the blood is occasionally found in certain organs of the body; that the amount of this pigment varies very much under conditions as yet unknown; that when present it obviously points to a greater destruction of blood than when it is absent; that as its presence is not constant, even in the same animal, no conclusion can be drawn from it as to the frequency or constancy of a process of blood destruction; therefore that, on the whole, there is no reason to conclude that any destruction of blood takes place except under exceptional circumstances, such as malaria and paroxysmal hæmoglobinuria.

## BILE PIGMENT AS AN EVIDENCE OF HÆMOLYSIS.

The evidence we have so far had before us differs in the case of bile pigment and blood pigment respectively. The close genetic relationship between the bile pigment and hæmoglobin and the daily formation of bile pigments afford presumptive evidence of a daily destruction of at least a certain quantity of hæmoglobin. This by no means points, however, to a daily destruction of blood; for, as we have seen, a certain amount of hæmoglobin may become effete (in the process of passive destruction of red corpuscles) without either the plasma or leucocytes participating—that is to say, without the occurrence of any destructive change in the blood as a whole. If, then, the formation of bile pigments can be subserved by passive destruction of blood-corpuscles—if the hæmoglobin thus rendered effete is sufficient to give rise to all the bile pigment daily excreted—it is clear that bile pigment as an indication of blood destruction loses much, if not all, its value. It then only remains an evidence of a certain slow destruction of red corpuscles. It thus becomes a matter of importance to ascertain by which of the two processes—an active or a passive destruction of red corpuscles—the formation of bile pigment is subserved.

As I pointed out earlier in this lecture, a large weight of evidence—more particularly that adduced by Minowski and Naunyn—points not only to hæmoglobin as the source of the bile pigments, but also to the liver as the

seat of this conversion. That being the case, the question now before us resolves itself into one as to the relative importance of the pigment cells within the capillaries and the liver cells themselves as seats of formation of bile pigment. For, as I have shown you, the former are *exclusively* the seats of the blood pigment derived from a passive destruction of red corpuscles, none, according to my observations, ever being found within the liver cells; while the latter, on the other hand, are, although not the exclusive, nevertheless the *chief* seat of transformation of the hæmoglobin derived from an active destruction of red corpuscles.

NECESSITY OF DISTINGUISHING BETWEEN CHANGES TAKING PLACE IN THE CAPILLARIES OF THE LIVER AND THOSE THAT TAKE PLACE WITHIN THE LIVER CELLS.

It may appear at first sight a matter of indifference where precisely within the liver this transformation of hæmoglobin into bile pigment takes place, whether within the capillaries, through the agency of leucocytes or kindred cells, or in the liver cells themselves. I cannot so regard it. On the contrary, nothing in this relation has impressed itself more on my mind than the necessity of distinguishing sharply, so far as that is possible, between processes carried on in the liver cells and others that take place within the capillaries, through the agency of the large mass of leucocytes contained within them. Let me in illustration show you sections of liver (Experiments 33 and 34) from two of my experiments, in which a large quantity of ultramarine blue in suspension was injected directly into the circulation of rabbits duly anaesthetised. You will see how abundant the pigment is in the liver—more abundant, indeed, than in any other organ, with the single exception of the lungs. Even during the injection the liver could be seen, on being exposed, to become markedly blue. On examination most of the pigment was found within leucocytes; not a single particle could be found within the liver cells. The arrest of this pigment and its accumulation within the liver was therefore due entirely to the activity of leucocytes and kindred cells, endothelial and otherwise, and not in any way to the action of the liver cells. We are not justified in speaking of such a function of the liver as on a parallel with other functions—for example, the glycolytic, more properly so termed. The two are not even comparable with one another in importance. The one is carried out exclusively by cells of leucocyte and endothelial nature, the other by the liver cells proper, and the only circumstance common to both is that they are carried out within one organ. So with this conversion of hæmoglobin into bile pigment. If it can be effected equally well by leucocyte or liver cell—if, indeed, as Quincke and Minkowski and Naunyn would seem to maintain from the importance they attach to the pigment cells within the capillaries, these cells play the chief *role* in the formation of bile pigment—then the formation of bile pigment would cease to be exclusively a hepatic function. There would be no reason why it might not be carried out in other organs of the body equally rich in such cells—for example, the spleen.

When, now, passing from these more general considerations, we come to the facts themselves, we find as follows: First of all, it cannot, I think, be doubted that ordinary cells of leucocyte and connective-tissue nature do possess a certain power of forming pigments apparently identical with those of the bile from hæmoglobin. The observations, amongst others, of Langhans, Cordua and Quincke are, I think, conclusive on this point. Langhans clearly showed that the pigments causing the well-known colours of bruises—subcutaneous extravasations—are of the same nature as those of the bile. Even more clearly if possible has this been demonstrated by Minkowski and Naunyn. They have shown that a green pigment, giving the reactions of biliverdin, may be found in the pigment cells within the liver capillaries in the goose. They found, moreover, that the increased formation of bile pigments, which they induced by exposing these animals to the fumes of arseniuretted hydrogen, went hand in hand with the appearance of large numbers of these cells in this situation. Sometimes only a single particle amidst the blood pigment within these cells gave the green reaction of biliverdin; at other times the whole cell substance appeared green. Their conclusion, then, that these pigment cells take a part, if, indeed, not the major part, in the formation of bile pigments from effete hæmoglobin would thus appear to be amply justified under the circumstances. Such a view as to the mode and seat of formation of bile pigment would coincide in all points

with the well-known observations (1880) of Quincke regarding the ultimate fate of the red corpuscles. According to Quincke, the normal fate of red corpuscles after a life duration extending for a period of from two to three weeks is to be taken up by the white cells of the blood and deposited in the capillaries of the liver, spleen and bone marrow. Within these cells their hæmoglobin is transformed into various products of an albuminate nature, partly coloured, partly colourless, and these are afterwards used up in forming new red corpuscles, or are got rid of by being excreted through the liver cells. Presumably during these changes, although as to this Quincke says nothing, the bile pigments are also formed. (It will be noted in passing that the fate of red corpuscles, as described by Quincke, corresponds with only one of the processes I have described as taking place in the blood, and that the less important—viz., passive destruction.)

Now, while admitting that the formation of bile pigment from hæmoglobin through the agency of leucocytes or connective-tissue cells is possible; while admitting, further, that the conclusions drawn by Minkowski and Naunyn from their observations appear amply justified, I nevertheless cannot admit that such a method of formation of bile pigment is even a common one, still less the usual one in health, and for the following among other reasons:

First of all, it appears to me that mistake is likely to arise if attention be directed too exclusively to one group of animals, and if the results thus obtained are applied directly, without correction, to animals of another group. This mistake has, I venture to think, been made, in some degree at least, both by Naunyn and Minkowski and by Quincke, the former having based their conclusions too exclusively on their observations on the goose, the latter on his observations on the dog; for in both these animals the presence of a certain number of pigment cells in the capillaries of the liver is, as we have seen, the rule. On the other hand, my observations on the rabbit, cat, guinea-pig, pig, and in man show that the presence of such cells is the exception; and this is, so far as my observations go, invariably the case in all young mammals, including even the dog. Individual differences exist in different animals in this respect, dependent mainly, as I believe, upon individual differences in the power of resistance of the red corpuscles—a power which admittedly varies in different animals. Be the explanation what it may, the fact remains that in the rabbit, for example—and most of my observations have been made on this animal—I have time after time examined the liver without finding a single pigment cell in its capillaries. To find them, indeed, has been the rare exception. Nevertheless, the excretion of bile pigment in the rabbit—as, indeed, in all herbivora—is, to say the least, fairly abundant. The daily excretion of bile is greater in the herbivora than in the carnivora. According to Bidder and Schmidt, in the cat and dog it is approximately 14 cc. and 19 cc. per kilo of weight respectively; in the rabbit and guinea-pig it is 136 cc. and 175 cc. per kilo respectively. With such an abundant excretion of bile, containing a considerable percentage of bile pigments, one might reasonably expect to find pigment cells in the capillaries of the liver if these are the source of the bile pigments. Still more might this be expected when it is borne in mind how permanent such blood pigment is, lasting, as it frequently does, for weeks, months and even years. Yet none are present. I am compelled therefore to conclude either that the mode of formation of bile pigments may vary in different animals—sometimes being effected through the agency of leucocytes, sometimes through the agency of the liver cells; or that its formation by the former, when it does occur, is altogether unimportant and insignificant, and the constant seat of this process is within the liver cell itself. The first conclusion seems to me altogether untenable, if only on general grounds. It appears to me altogether improbable that a function so characteristic of the liver as that of the formation of bile pigments should, after all, be discharged, not by the special glandular structure—the liver cell,—but by ordinary cells of leucocyte and endothelial nature lying adjacent to the liver cell. Moreover, on such a view it is difficult to understand why bile pigment is not formed by the cells of the spleen, seeing that sometimes they are even more abundantly supplied with blood pigment than the leucocytes within the liver. Even Minkowski and Naunyn, however, have failed to find any trace of biliverdin in the pigment cells of the spleen.

So much, then, for the evidence pointing away from ordinary

pigment cells, even when situated in the capillaries of the liver as the ordinary seats of formation of bile pigment, and pointing away in a corresponding degree from passive destruction of red corpuscles as the source of the hæmoglobin thus transformed. I have now to draw your attention to evidence pointing to the liver cells as the seat of this transformation, and to an active destruction of red corpuscles as a necessary precursor of this process, and that, too, not only in mammals, but also in birds. I have shown you that nothing more clearly indicates such an active destruction of red corpuscles than the presence of minute granules of blood pigment in the liver cells, more especially in those of the portal zone of the hepatic lobule. I have shown you, moreover, that, although not constant, such pigment is very frequently found in the liver cell, more especially in birds; to a much less extent in mammals.

It now remains for me to show, from my experiments, that an increased formation of bile pigments is more frequently associated with an increased deposit of blood pigment within the liver cells than it is with an increase of pigment cells within the capillaries. Further, that such an increased formation is frequently attended solely by an increase of blood pigment in the former situation, not a particle of pigment or a single pigment cell being discoverable within the capillaries. And lastly, that a large increase in the pigment cells within the capillaries can take place without any increased formation of bile pigments (Experiment 89). To illustrate the first two points I now show you a section from Experiments 42 and 43. Two healthy rabbits received at intervals doses of toluylendiamine as follows, the injections being made subcutaneously:

*Experiment 42.*

Sept. 19th ...	0.18	gramme per kilo.	of weight =	0.5	gramme.
"   20th ...	0.13	"   "   "	"   "   "	= 0.35	"
"   26th ...	0.18	"   "   "	"   "   "	= 0.5	"
"   29th ...	0.36	"   "   "	"   "   "	= 1.0	"

When killed, on Oct. 13th, it had lost 3 oz. in weight.

*Experiment 43.*

Sept. 15th ...	0.18	gramme per kilo.	of weight =	0.5	gramme.
"   19th ...	0.15	"   "   "	"   "   "	= 0.4	"

When killed, on Sept. 20th, it had lost 6 oz. in weight.

In both cases, especially in Experiment 42; you will note the great abundance of fine pigment within the liver cells, all of it giving the reaction of free iron. So small are the individual particles, indeed, that it is only with higher powers (300 or more) that their great number and their precise situation within the liver cells can be properly made out. In both cases, moreover, no less striking than its abundance in the liver cells is the absence of pigment cells from the capillaries. The bearing of these observations will be at once obvious when I state that, as will presently be seen, toluylendiamine causes an increased formation of bile pigments and distinct destruction of blood—viz., an acute destruction of red corpuscles. That the blood pigment within the liver cells owed its origin to the destruction of free hæmoglobin within these cells there can, as we have seen, be no doubt; and the conclusion may, I think, be permitted that it was likewise within the liver cells that the bile pigments so largely excreted were also formed. Evidence of a similar kind pointing to the same deduction was afforded by experiments on pigeons and observations on man. From these observations I infer that it is within the liver cells, and not in the capillaries, that hæmoglobin is transformed into bile pigment. The hæmoglobin thus transformed must have escaped from the red corpuscles before passing into the liver cell. In short, the source of the bile pigment is free hæmoglobin.

It will thus be seen that, although I do not absolutely deny to pigment cells of leucocyte and connective-tissue nature, such as we occasionally find in the capillaries of the liver, the power under certain circumstances of forming pigments similar to the bile pigments from hæmoglobin, I am undoubt'edly of opinion, for the reasons above stated, that such a mode of origin of the bile pigments is altogether secondary in importance to their derivation from the liver cells. For not only are such pigment cells frequently entirely absent from the tissues of animals in which an undoubted, it may be even a largely increased, formation of bile pigments is taking place, but also, what is even more significant, a largely increased formation is frequently marked by an increase of the blood pigment in a situation where it can only, in my opinion, be derived from free hæmoglobin—namely, within the liver cell. Such an escape of hæmoglobin

from the red corpuscle into the plasma of the blood being, as we have seen, the chief feature of an *acute* as distinguished from a *passive* destruction of red corpuscles, the answer which my observations supply to the question with which we started is that: (1) the formation of bile pigments by the liver is subserved by an active destruction of red corpuscles and not a passive one; (2) a certain destruction of blood is therefore a phenomenon of daily occurrence.

ABSTRACT OF A

Clinical Lecture

ON A

CASE IN WHICH SUCCESSIVE ANEURYSMS WERE TREATED BY LIGATURE OF FOUR LARGE ARTERIES.

By ALEX. O. MACKELLAR, M.Ch. Q.U.I.,  
F.R.C.S. Eng. &c.,  
SURGEON TO ST. THOMAS'S HOSPITAL.

GENTLEMEN,—The subject of our clinical lecture to-day is a case you are well acquainted with, the patient having been in the hospital three times and having undergone the ligation of no less than four of the main arteries for the treatment of aneurysms. He was first admitted on March 9th, 1888, suffering from a popliteal aneurysm with a large sac, which was rapidly increasing. He was thirty years of age, and by occupation a police constable; previously he had been a soldier in Egypt and also a professional runner, his best time being one hundred yards in ten seconds and a quarter. He had had venereal disease, but there was no certain history of syphilis. The aneurysm was of the right popliteal artery, and was attributed to slipping off the kerb, when he felt "something give way." This was one month previous to admission. The superficial femoral artery was tied with a silk ligature. All pulsation at once ceased in the aneurysm, and the patient made a satisfactory recovery. He was readmitted a year later, suffering from an aneurysm of the other popliteal artery. There was no history of injury. On this occasion treatment by digital compression was tried for thirty-one hours, but no improvement resulted, and on Aug. 23rd the left superficial femoral was ligatured with silk. Pulsation in the aneurysm at once ceased, and the patient recovered. In February, 1892—that is to say, four years after his first admission—our patient was admitted for the third time; on this occasion he was suffering from a pulsating swelling, clearly an aneurysm, behind and above the manubrium sterni. In the previous November he had fallen from and under his horse. For this aneurysm the right common carotid and the third part of the right subclavian were simultaneously ligatured; this was on Feb. 22nd, 1892. The carotid was tied with silk and the subclavian was tied in two places and divided between. These operations seemed for a time to arrest the progress of the aneurysm, which subsequently gradually increased, and finally ruptured through the skin, the patient dying of hæmorrhage on May 19th, 1892. A minute examination of the ligatured vessels and aneurysms was made by Messrs. Ballance and Edmunds, but instead of reading their report it will, I think, be more instructive for us to go through the case again, discussing the various points that arise in the light of what we now know. The patient, then, was admitted suffering from popliteal aneurysm, which was treated by the operation first practised by John Hunter at St. George's Hospital in December, 1785. Before this, popliteal aneurysms were treated, if treated at all, either by amputation or by laying the aneurysm open, turning out the clot and ligating the two ends of the artery; this latter operation was almost invariably fatal. With a view to reduce this mortality Hunter devised his great operation; as you know, he tied the femoral in Hunter's canal, and this alone sufficed to cure the aneurysm. He had himself lost an apparently favourable case of popliteal aneurysm treated by the old operation from hæmorrhage, and he contrasted this with the freedom from hæmorrhage after amputation. "Why not then," he asks, "tie the artery where it can be safely tied in amputation and save the limb"? This he did, and the procedure has constituted one of the greatest

advances in surgery that it has ever fallen to the lot of one man to make. Hunter himself saved four out of the five cases on which he operated, and other surgeons were equally successful. French surgeons have claimed that Hunter's operation was merely a revival of that performed by Anel eighty years previously. Anel had been called on to treat a monk suffering from an aneurysm of the brachial artery accidentally caused by venesection; Anel tied the brachial immediately above the aneurysm, which was thus cured.

Now, the differences between Anel's and Hunter's operations are: First, that Anel's was on the arm and Hunter's on the leg; this is a great difference—for instance, the blood-supply of the arm after ligation of its main artery is much better than that of the leg; gangrene is very rare in the arm. A second difference is that Anel tied immediately above the aneurysm, whereas Hunter tied at some distance from it. From a pathological point of view Anel's may be the better procedure, but it is far easier for the surgeon to tie the superficial femoral artery than to seek the popliteal in the ham, in close proximity to a large pulsating tumour, a procedure which Anel, be it understood, neither practised nor recommended. It has sometimes been stated that the cause of the failure of the old operation was that the artery was diseased near the aneurysm. This, however, Hunter himself pointed out was not the case, and you will see the same in the specimens on the table. Another reason for the success of Hunter's operation has been given—namely, that by it a small current of blood is allowed to trickle through the aneurysm after the ligation of the artery, thus causing the deposit of laminated clot. You will remember that in neither of these popliteal aneurysms after the ligation was there the slightest pulsation; this is nearly always the case in popliteal aneurysms. Pulsation in them immediately after ligation is either due to a double superficial femoral, as in Bell's case, or to the artery being imperfectly occluded. Later recurrent pulsation may happen from excess of the collateral circulation, and this may be so extensive as to prevent the cure of the aneurysm. Failure from this cause is happily very rare; the treatment is rest, and if this fails religation nearer the aneurysm.

As to laminated clot, when it is found in a popliteal aneurysm after ligation it has been formed before ligation, and is not due to any trickling of blood through the aneurysm after ligation. On ligation the cavity of the aneurysm and the popliteal artery become filled with clot, which later is converted into fibrous tissue, the whole aneurysm being represented, as you see in the specimens before you, by a shrunken mass of fibrous tissue. The ligature which I used was silk boiled in a perchloride of mercury solution. Innumerable substances have been recommended for this purpose, but silk has this great merit—that it can be readily and certainly made aseptic by boiling, a treatment which catgut and other animal ligatures will not stand. Ever since arteries have been ligated surgeons have had to consider how tightly the ligature should be drawn; whether, in other words, the two inner coats should be ruptured or not. Paré, who reintroduced the ligature, endeavoured not to injure the vessel, and Hunter took the same view; but in the early part of the present century Jones in his classical work on hæmorrhage gave the result of numerous experiments, from which he concluded that the coats should be ruptured. It must be remembered, however, that in these days of antiseptics and absorbable ligatures the problem is widely different from what it was in Jones's time, when the ligature had to work its way through the vessel and be discharged externally. Jones's experiments, too, as he points out, were incomplete. He made no experiments without rupture of the coats; these Scarpa made a few years later, and he arrived at the opposite conclusion. So the controversy has gone on, the latest contribution to it having come from our hospital. For myself, I think it has now been conclusively proved, both by experiments on animals and experience in man, that the coats should *not* be ruptured; in arteries of any size it is unnecessary, in the case of the largest arteries it is to invoke the gravest risk of hæmorrhage. In trying not to rupture the coats one has to be careful not to fail to occlude the vessel. It is clear that with a reef knot the ends must be slackened for an appreciable time in order to make the second hitch, and this gives an opportunity for the pressure of the blood to redistend the loop of the ligature. Tying the second hitch tightly will not tighten the loop. To obviate this the so-called surgeon's knot has been devised and it was this knot that I used for the femoral that was first tied. This knot does not answer this purpose—indeed, some say it is inferior to a reef

knot. Another way of meeting this difficulty has been devised by Messrs. Ballance and Edmunds. The aneurysm needle draws a double ligature under the artery and if the loop is divided two ligatures lie side by side. Both these are to be used. The first hitch of a reef knot is tied on each separately, then the two ends on one side are taken in one hand and the two ends on the other in the other hand, the loops being drawn sufficiently tight to occlude the artery; the knot is then completed as a reef knot by treating the two ends in each hand as single threads. This is called a "stay knot." It has been objected that it is a somewhat bulky knot. I did not find it so with silk; but if you prefer it you can complete each reef knot separately, the principle being that the friction in the two single hitches first made and between the two loops offers so much resistance to distension by the pressure of the blood that ample time is allowed to complete the knot; a further advantage is that with two loops there is a great range between the force which is just sufficient to occlude and that which just stops short of rupturing the coats, thus there is little fear of injuring the vessel. The stay knot, I may say from experience, is not at all complicated—indeed, if the knot is completed as two separate reefs, it is simplicity itself. I used the stay knot for the left femoral and the common carotid—with what result we will now see.

We will commence with the report on the right femoral which had been tied with the surgeon's knot four years before death. For about three-quarters of an inch at the seat of ligature the lumen is occluded, with the exception that a very fine bristle can be made to enter it. This tiny winding channel is crossed by several perforated diaphragms, the coats are uninjured, but apparently were not quite brought into contact by the ligature and the vessel is practically impervious; above and below the seat of ligature the vessel is patent, but is much diminished in size. No trace of the ligature could be seen. Below the vessel was patent down to the aneurysm, where the popliteal artery and aneurysm were together converted into a small mass of connective tissue. The left femoral had been tied with a stay knot three years before. The vessel was blocked at the seat of ligature by fibrous tissue (organised clot) for about half an inch; in this were minute holes, along which a bristle would not travel, owing to the openings not corresponding in what may be called the successive diaphragms. The coats could easily be followed and had not been injured by the ligature, but appear not to have been brought quite into contact, the closure being completed by a clot which subsequently became converted into fibrous tissue. The vessel was patent above and below the seat of ligature; no trace of the ligatures was seen. The condition of the artery below and of the aneurysm was the same as on the right side. The right common carotid: at the seat of ligature for three-quarters of an inch the coats are uninjured, in contact and adherent. The whole length of the vessel above and below this was filled with clot; the ligatures were encapsuled in connective tissue. In all three cases the whole seat of ligature was enveloped in a small fusiform mass of connective tissue. The ligatures on the femorals fully answered their purpose, and that on the common carotid seems to have been ideal.

With respect to the subclavian artery, you will remember that as the aneurysm needle was being passed the vessel gave way, and I had to treat it as a wounded artery—namely, by applying a ligature above and below and dividing the vessel between them; the ends, you will see, are separated by half an inch and lie in a mass of fibrous tissue. On the proximal side there is no clot whatever, although the inner coat has been ruptured and is recurved, and though the nearest branch above is one inch and a quarter distant from the seat of ligature. On the distal side there is a clot extending to the first branch—that is, for half an inch. The silk ligatures have ulcerated through the vessel and lie in minute inflammatory cavities just large enough to hold them at the side of the vessel. On the patient's third and last admission to the hospital there was an obvious aneurysm behind the manubrium sterni. It must not be inferred that an aneurysm in this position is of the innominate artery, for aneurysms frequently spring from the front of the arch and pass up in front of the innominate. This, in fact, was what was eventually found to be the case in this patient. The aneurysm was a sacculated one, communicating by an opening the size of a shilling with the arch of the aorta, just in front of the origin of the innominate, which was perfectly normal. There are several specimens in our museum of these aneurysms; in one, the aneurysm arises, as in our present case, from the

norta alone; in a second, by an opening common to it and the innominate artery; in a third, the opening of the aneurysm is from the innominate, but only from just within its mouth. It is not possible from the position, then, of the aneurysm to determine whether it is innominate or aortic. With respect to other symptoms, the most important is the comparison of the two radial pulses; if the right is decidedly weaker the innominate is probably involved. The various pressure symptoms may be caused by aneurysm of either artery.

With respect to the treatment by distal ligature, it is to be remarked that if the aneurysm is purely aortic the operation can only offer temporary relief, though several cases are now on record in which much good appears to have been done. In the case of purely innominate aneurysms a cure probably would be obtained if a method could be found of preventing the passage of any blood along the innominate artery; but this is not effected by the ligature of the carotid and the third part of the subclavian. In the present case the innominate and the whole length of the subclavian as far as the seat of ligature were patent, so that a large amount of blood continued to flow through the innominate after the operation. Clearly the ligature of the carotid reduces considerably the amount of blood flowing through the innominate, but the good effect of tying the third part of the subclavian is not so clear, since the collateral circulation for the arm and brain is supplied partly by the branches of the first and second parts of the subclavian. On this account some surgeons have recommended that the vertebral should also be tied, but the operation for these cases, if it were only feasible, would be the ligation of the first part of the subclavian; this operation up to the present time has always been followed by fatal hæmorrhage, but it is encouraging to remember that Smyth of New Orleans has ligatured a larger artery—namely, the innominate—with success; we may therefore be permitted to hope that with the progress of surgery the operation may yet be successful.

## THE MASTOID ANTRUM IN CHILDREN.

By ARTHUR H. CHEATLE, F.R.C.S. ENG.,

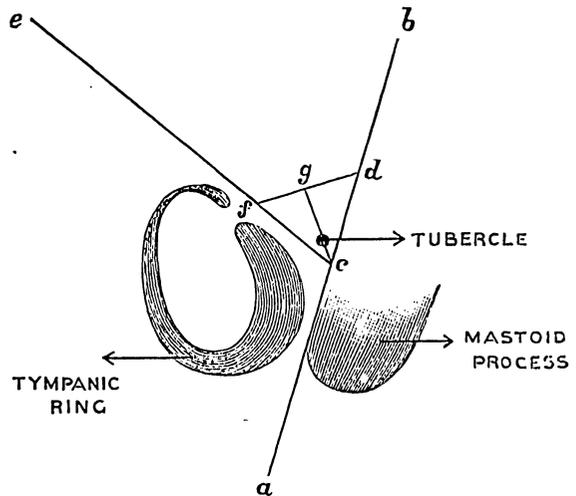

LATE HOUSE SURGEON AND HOUSE ACCOUCHEUR, KING'S COLLEGE HOSPITAL; AND JUNIOR RESIDENT MEDICAL OFFICER AND REGISTRAR, EVELINA HOSPITAL FOR SICK CHILDREN.

MR. ARBUTHNOT LANE has drawn attention to the great importance of the mastoid antrum in connexion with the functions and diseases of the middle ear. After reading his papers I examined the cavities of a number of children whose ages ranged from one to twelve years, and found that they presented very uniform appearances and relations in each case, and admitted of the following description:—The mastoid antrum is a cone-shaped cavity with rounded angles, situated in the most external portion of the petrous bone, the base being turned towards the middle fossa of the skull, the apex running downwards, backwards and outwards, abutting on the base of the mastoid process, opening at its upper and anterior aspect into the recess immediately above the incus; a line drawn from the centre of the base to the apex, forming about an angle of 45° with the direction of the mastoid process, measuring from a quarter to three-eighths of an inch from base to apex, the same in diameter at the base, gradually narrowing to the apex; lined with mucous membrane continuous with that lining the rest of the tympanic cavity and containing a viscid fluid. As regards its development, it is the cavity enclosed by the junction of the projecting lips of the mastoid sulcus, which join posteriorly with the lamellæ of the horizontal portion of the squamous division, the upper lip with the posterior part of the internal lamella, the lower with the posterior part of the outer, the inner surface of the outer lamella being cellular, where it forms the outer wall of the antrum.

For the purpose of describing its relations to surrounding parts it presents for examination a base or roof, an apex, an opening, and external, antero-internal and postero-internal walls. The roof forms a portion of the floor of the middle fossa of the skull, and corresponds to a surface of bone on the superior surface of the petrous bone from one-fourth to three-eighths of an inch in diameter, slightly external to the eminence formed by the superior semicircular canal, irregularly circular or triangular in outline, and formed by the upper lip of the mastoid sulcus overlapping the internal lamella of the horizontal portion of the squama, the petro-

squamous fissure often being evident, after stripping off the dura mater, which sends a process into it, and occasionally a fine bristle may be passed through it into the cavity. The roof is generally thin, often cellular under the upper layer of compact bone; to remove it, commencing from behind, is the easiest way of demonstrating the cavity, the lining mucous membrane often remaining intact. The apex abuts on the base of the mastoid process, sometimes pointing straight into the groove for the lateral sinus—the intervening portion of bone being smooth, extremely thin and translucent,—at other times pointing more towards the mastoid mass, being either smooth or cellular and never having any communication with that process. The antero-internal wall formed by the mastoid sulcus is generally reticulated, and is in relation at its upper and posterior aspect with the semicircular canals (the superior on a slightly higher level), being separated by a layer of dense bone which increases in thickness from the front backwards and measuring about one-eighth of an inch behind. In front of the canals and on a lower plane is the facial nerve in its canal, also separated by a layer of dense bone from one-sixteenth to one-eighth of an inch in thickness; the wall soon slopes away from these structures, narrowing to the apex. A gap is left at the upper and anterior angle, forming the opening of the cavity.

Voltoni describes a canal occasionally leading from the fossa subarcuata, or the depression below the superior semicircular canal, into the mastoid cells. I have a specimen in which the canal opens into the antrum on the antero-internal wall. The postero-internal wall forms a portion of the posterior fossa of the skull, corresponding to a roughly triangular surface on the posterior surface of the petrous

bone, external to the semicircular canals, the base upwards; it is often smooth, thin and translucent, sometimes cellular towards the cavity. The relation of the groove for the lateral sinus varies considerably, sometimes the groove covering a considerable portion of its outer and lower aspects, at other times only its lower aspect, or not coming into relation with it at all, but skirting external to and below it. Between the roof and the postero-internal wall the superior border of the petrous bone projects into the cranial cavity, along which runs the superior petrosal sinus, enclosed in the tentorium cerebelli. The external wall is roughly triangular in shape and always lined at its superior and anterior aspects with a layer of intercommunicating cells, all of which open eventually into the main cavity; it is formed by the posterior part of the outer lamella of the horizontal portion of the squama, joining with the lower lip of the mastoid sulcus, evidences of the fissura mastoideo-squamosa often being visible. This wall corresponds on the external surface with a depression felt behind the attachment of the auricle at its upper part, above the mastoid process. A small tubercle may often be felt close to the attachment of the auricle, separated from the mastoid process by a slight groove; if a hole be drilled straight in at this tubercle it will open into the antrum, as a rule just above the apex. A rough method of marking out this wall on the exterior is to draw a line along the anterior edge of the mastoid process, parallel to the main direction of that process (see diagram, a, b). In this

line take a point, *a*, at the base of the process, and from it measure upwards a quarter of an inch to *d*; from the same point, *a*, draw a line, *ae*, forwards and upwards, forming about an angle of 70° with the line *ab*; from *a* measure along it a quarter of an inch to *f*; on joining *f* and *d* a triangle will be marked out corresponding fairly well with the surface of bone covering in the cavity. Again, if a line, *og*, be drawn through the centre of the line *fd* to *o*, it will closely correspond to the junction of the antero-internal and postero-internal walls; it will be seen that this external wall forms a wedge-shaped piece of the posterior meatus at *f*. The thickness of the wall varies both as regards its inner cellular and its outer compact linings; sometimes the wall is translucent owing to the outer layer being thin, at other times this outer layer measures from one-sixteenth to one-eighth of an inch in thickness and is of extreme density, but both layers seem to increase with the age of the child. The opening corresponding to the gap in the antero-internal wall is situated at the upper anterior aspect of the cavity; the margin of the gap, together with the roof and external wall, form a triangular space with the base upwards, the sides of the triangle being about equal, each measuring about one-eighth of an inch. At the apex is lodged the tip of the horizontal process of the incus, the orifice of the canal for the chorda tympani being immediately internal to or below this. Running parallel to the internal boundary and about one-eighth of an inch from it is the facial nerve in its canal. A probe might possibly be passed into the opening through the meatus after removal of the membrane and ossicles; I have never tried this, but with a suitably bent probe it might be managed. So that, as Mr. Lane points out, the cavity must be regarded as a part of the middle ear, serving to secrete and store up the viscid fluid which lubricates the tympanic cavity and its contents; it is also evidently in the most advantageous position for such a purpose, and movements of the head no doubt help in the evacuation of its contents. With such functions and connexions it ought to be described, both developmentally and anatomically, as part of the petrous bone and not of the mastoid, especially as the division of the petro-mastoid is purely an imaginary one. The name also is misleading. A more correct and descriptive one would be "tympanic receptaculum."

Vienna.

## INVESTIGATIONS INTO THE ETIOLOGY OF MEDITERRANEAN FEVERS.

By SURGEON-CAPTAIN LOUIS HUGHES, A.M.D., MALTA.

MUCH has been written about a tedious form of fever prevalent along the coasts of the Mediterranean which, though quite distinct from enteric fever on the one hand or intermittent (malarial) fever or ague on the other, yet often occurs side by side with these diseases, and has so close a relationship with them as to be frequently called by the unscientific hybrid term "typho-malaria." Whether or not it is identical with cases of so-called typho-malaria occurring in India,<sup>1</sup> America,<sup>2</sup> China,<sup>3</sup> South Africa<sup>4</sup> &c., I cannot at present say, but it is very evident that the same fever exists at many points along the Mediterranean, where it is known as "Malta fever," "Rock or Gibraltar fever," "Neapolitan fever" &c., and for want of a better name I shall here call it "Mediterranean fever." It is said to bear a very close resemblance to some chronic forms of remittent fever met with in India. This present abstract from a detailed report lately rendered to the War Office is the result of eighteen months' work in Malta, where no endemic malaria (ague) exists, and where, both in the wards and in the laboratory, I have had the opportunity of treating and seeing some hundreds of cases of this fever, and I bring it forward hoping thereby to establish the etiology of this fever on a firmer basis.

1. That there is a fever present in the Mediterranean having such distinct and constant features both clinically and pathologically as enables it to be identified from other diseases has been well worked out by Marston,<sup>5</sup> Veale,<sup>6</sup> Bruce,<sup>7</sup>

Moffat<sup>8</sup> and many others,<sup>9</sup> and without entering into details I will mention a few of its leading characteristics. Clinically it has a peculiarly irregular temperature curve, consisting of intermittent waves of pyrexia of a distinctly remittent type, each wave lasting from one to three weeks, with generally an apyrexial interval of two or three days. In rarer cases the remissions may become so marked as to give it an almost intermittent character, but distinguishable clearly from the paroxysms of ague. This pyrexial condition is usually very chronic, lasting even six months or more, and is not markedly affected by quinine or arsenic. It is usually accompanied by obstinate constipation, progressive anæmia and debility, and is followed, in a large number of cases, by very chronic neuralgic and rheumatic complications, from which the patient may not recover for perhaps two years. The death-rate is very low; but as the average stay in hospital is from seventy to ninety days, the expense incurred by the State for invaliding and non-effective pay, both in the army and navy, since our occupation of the Mediterranean has reached an enormous sum. During last year, after eliminating all cases of febricula and enteric fever as far as possible, in Malta alone it was reckoned that the loss to the State on account of this fever was equal to the value of the services of the whole non-commissioned garrison (7697 men) for over three days. The fever is both endemic and epidemic in character. Pathologically the spleen is at first much enlarged, but about the fifth or sixth week it becomes harder, and occasionally shrinks to even less than its normal size. The alimentary tract is subject to irregular patches of congestion, but this has no relation to Peyer's patches, which are not affected. The mesenteric glands are enlarged, but less so than is the case in enteric fever. There is no so-called malarial pigmentation (Klebs and Crueldi).

2. A micro-organism distinguishable from others by its appearance and mode of growth has been found in those parts of the body where from clinical symptoms and post-mortem appearances one would expect to find it, and it is, I hold, present in every case. I have now been successful in obtaining from the spleens of five men who undoubtedly died of Mediterranean fever (duration varying from nine days to five months) a special micro-organism similar in every respect to that discovered by Surgeon-Captain Bruce, A.M.D.,<sup>10</sup> in eight cases, and by Surgeon Gipps, R.N.,<sup>11</sup> in two cases, making in all fifteen cases. This micro-organism I have in each of my cases carried through six generations of pure cultivations. In two cases I was able to demonstrate microscopically its presence in fresh splenic substance. The only case in which it was not found was accounted for by the use of excessively alkaline agar, as I have since proved by control experiments with pure cultures from other cases.

3. I have met with no other micro-organism present under similar circumstances, nor do I know of any other disease in which this micro-organism is present, though test experiments have been made in various fatal cases from other causes. In all fatal cases of enteric fever I have so far found an organism present in the spleen corresponding in appearance and manner of growth with that described by Eberth and Gaffky.

4. Pure cultivations of this micro-organism have been introduced, twice by Bruce<sup>12</sup> and twice by myself, into the muscles of the forearm of healthy monkeys that have previously been under observation for periods of between two and four months. A colony was mixed with sterilised bouillon and the strictest precautions taken. No local changes occurred at the seat of inoculation. In each case the temperature began to rise in about thirty-six hours, and followed the acute course of severe attacks of this fever. The former two monkeys died and my own two were killed during the third week of the fever, having temperatures between 106° and 107° F. In each case pure cultivations of a similar organism were obtained from the spleen and liver, and in my own cases from the blood, of these monkeys. Five minutes after death the liver and spleen appeared large and congested, and there were irregular patches of intestinal congestion. Peyer's patches were normal, as were also the mesenteric glands. The micro-organism was carried through six generations of pure cultures. Again, pure cultures obtained from the spleen and blood of one of my monkeys were injected into the forearms of two other monkeys, pre-

viously under observation for from four to nine weeks respectively and having during that time steady temperatures, never over 100° F., their normal temperature being about 99° F. In about thirty-six hours the temperature rose, and though there were no pathological signs at the seat of inoculation, yet these two monkeys suffered from fever for two and a half to three months respectively. They lost weight, and in spite of the weather being warm suffered at times, apparently from rheumatism of the arms and legs, but eventually recovered. Their temperatures were taken carefully three times a day, and showed in a most remarkable manner the typical intermittent waves of remittent pyrexia, and there can be no doubt that they were suffering from true Mediterranean fever.

5. This micro-organism, which I believe to be the proximate cause of Mediterranean fever, grows best in nutrient material the alkalinity of which is slightly less than that of human blood, and at a temperature of from 37° to 39° C. On the sloping surface of a 1½ per cent. peptone agar, at a temperature of 37° C., its colonies become visible to the naked eye in from 120 to 125 hours after primary inoculation from the human spleen. They first appear as minute, transparent, colourless drops on the surface of the agar. In about thirty-six hours they become of a transparent amber colour, and, increasing very slowly in size, become opaque in from four to five days from their first appearance. At this time they somewhat resemble split pearls lying on the agar surface. Under a low power with transmitted light the colonies appear of an orange colour, quite round, and with a definite but granular margin. If kept on moist agar they increase in size, but remain circular in shape, and gradually coalesce. In the course of three months they turn to a bright buff or even orange colour, and increase in thickness by heaping up at the centre of the colony, but never attain a great diameter. No liquefaction occurs. Though they cease to grow at the end of two months the colonies retain their vitality at a suitable temperature for over three months. They cease to grow at 18.5° C. and die if kept long at a moist temperature below 15.5° C., but live a long time in a dry state. They will not grow as primary growths on agar having an alkalinity in excess of the blood, but if cultivated in successive media of increasing alkalinity they may be educated to grow in very alkaline media. In this case, however, they are longer in appearing, and grow more slowly and in a very diffuse manner over the surface of the agar, showing at the same time many abortive attempts at colonisation. These diffuse growths, however, if transferred to agar having a suitable alkalinity, again revert to their original characteristic form of growth. They grow also in gelatine and bouillon. In the former it grows very slowly at 22° C. without liquefying. In the latter it gives rise to a general and increasing opaqueness, commencing on the fifth or sixth day and afterwards forming a white precipitate consisting of these cocci, but without forming a surface pellicle. Microscopically in the hanging drop they appear as very minute cocci, 0.008-0.3 mm. (Bruce), ovoid or nearly round in shape, in rapid molecular motion, and at times to be seen in chains composed of two or more. They stain readily with gentian or methyl-violet and fuchsin, but lose their stain rapidly if treated with alcohol. Mounted in balsam they appear as minute cocci, here and there arranged in short chains. They can be observed in fresh splenic substance after death and in the blood during life of man suffering from this fever.

6. From accessible data collected from statistics and records of the last seventy years, from investigations during a recent localised epidemic, from the distribution, and more especially from a comparison of the dates of admission of cases of this fever with the amount of rainfall, it would appear that its presence in Malta and Gibraltar is connected with human excrement, as is said to be the case with enteric fever. The above facts have also drawn me to believe that the poison of this fever, when infecting the human body, is aerial in nature, and arises from faecal and organic matter in porous soils when these are undergoing a process of drying, somewhat after the manner in which the miasm of malaria (ague) is said to be given off from suitable sources, and that in most cases it enters the human frame by way of the air passages. I have no evidence in favour of infected food or drink having any causal connexion with this fever. Its occurrence as an epidemic will be found, I believe, to be preventable. What is now needed is a suitable name and place among fevers in the published standard works, that it may no longer be described as abortive and modified enteric fever or ague, nor be classed as climatic variations of these two specific diseases. Its etiology is of great importance to England, as the Medi-

terranean, besides being a great winter resort and a half-way house in which to acclimatise regiments proceeding to England, has also a permanent force of over 24,000 English soldiers and sailors, who are all more or less exposed to the effects of this fever, both in garrison towns and at the various foreign ports which our squadron visits.

## COMPOUND FRACTURE OF THE INFERIOR MAXILLA TREATED BY WIRE SUTURE.

By T. S. CARTER, L.D.S.R.C.S.ENG.,  
DENTAL SURGEON TO THE LEEDS GENERAL INFIRMARY.

THE obstacles which have to be overcome in order to maintain fractured portions of the inferior maxilla *in situ* are so numerous that I desire to record the method which I have adopted in several cases with equally good results. The great advantages over other methods are the perfect rigidity of fractured portions, neatness, cleanliness, absence of a bulky splint and an earlier use of the maxilla for masticating purposes.

A powerful wherryman aged nineteen was admitted into the Leeds General Infirmary on May 11th, suffering from compound fracture of the lower jaw &c. A gutta-percha splint and a four-tailed bandage were applied, but without effect, and on May 19th I was asked to see the case. I found the lower maxilla fractured transversely across the ramus on the patient's left side, also perpendicularly between the two fangs of the first molar on the same side, and likewise perpendicularly through the socket of the second bicuspid on the patient's right. The front portion was much displaced, being deeply depressed and exposing the second fang of the molar in its full length. The front portion was also considerably overlapping the posterior part, carrying the median line of the maxilla considerably over to the patient's left side. I took impressions in wax of both maxilla. On May 20th the patient was anaesthetised, and with a dental engine and a specially made bayonet-shaped drill I made a hole through the jaw between the first and second molars on the patient's left side, holding an oral spoon on the inner side to guard the drill from piercing the root of the tongue. I next passed a stout silver wire through the drilled hole and bored a second hole between the fang of the canine and the first bicuspid, and, having brought the wire through from the inside, twisted the ends together and tightened them with pliers, I bent the tail down flat, so as to be out of the way. The chief difficulty in these cases is to return the wire after having passed it through the first drill hole. The method I adopt is as follows:—While drilling the hole I hold, or get a dresser to hold, an oral spoon on the inner side as a tongue guard. Having pushed the wire through into the bowl of the spoon, the latter curls it from the tongue and one can then seize it with a pair of forceps. I then bend a long loop on it and, having passed a fine wire through the second drill hole, attach it to the loop and draw it through. The oral spoon is a great help by safeguarding the tongue, turning the wire, and preventing the finger from being lacerated in feeling for the wire—an important factor in cases of a specific character. In addition to the suture I applied a Hammond's splint, which fixed the fractured portion on the patient's right, and finally a well-ventilated gutta-percha splint.

On May 26th the parts were in a most satisfactory condition. There was no discharge and the patient was free from pain. On June 2nd the portions wired together were in perfect position, but the back teeth met before the front ones, probably owing to the fracture through the ramus. A broad cotton bandage (double thickness) was applied, the frontal portion being tightened in order to raise the body of the jaw. On the 11th the teeth were well opposed to each other. The patient was free from pain, and all looked healthy. He was made an out-patient. On July 7th the bandage and Hammond's splint and wire suture were removed. All was found firm and in good position. To avoid future trouble from the stumps on the patient's left side I removed them.

In a case which I attended some time ago there was the same happy result. The inferior maxilla was divided in the median line to facilitate the removal of cancer from the floor of the mouth. There was difficulty in obtaining union in the ordinary way, but the application of a strong wire suture, applied as described, answered most efficiently, and there was rapid union.

Leeds.

THE  
PREVENTION OF SUICIDE IN THE INSANE.<sup>1</sup>

By H. SUTHERLAND, M.D. OXON., M.R.C.P. LOND.,  
PHYSICIAN TO ST. GEORGE'S (HANOVER-SQUARE) DISPENSARY.

THE following remarks on the prevention of suicide in the insane are of a practical character, and may, I hope, be found useful to those who are engaged in the treatment of the insane, whether such treatment be carried on in an asylum or in the house of a physician. In the first place I shall refer to a few statistics as briefly as possible. The population of England, according to the last report of the Registrar-General, was 29,001,018, of whom 13,152 committed suicide. The number of lunatics in England and Wales was 87,848 at the same date, of whom only 12 committed suicide. Roughly speaking, 1 in 14,000 sane people and 1 in 7000 insane people—that is to say, twice as many insane as sane—commit suicide. It is impossible to say how many of the population at large have suicidal propensities, but if we turn to the tables of the Commissioners in Lunacy we find that not less than one-third of the patients admitted are entered in the case books as suffering from this tendency. In the year 1888 the number of patients admitted amounted in all to 14,000, and of these not less 4000 odd had suicidal propensities. When we compare the number of patients who have suicidal tendencies with the actual number who commit suicide, it must be confessed that we owe a heavy debt of gratitude to those by whose skill and obedience this calamity is reduced to so small a proportion. Out of 4217 patients with suicidal tendency, only 19—that is, only one case out of 222—succeeded in committing the act, the remaining 221 having been prevented from accomplishing the fatal deed by the care and vigilance of the attendants. It is the relatives of the insane who are responsible for the majority of suicides. They delay the admission of patients until some awful tragedy occurs; they interfere unnecessarily with the treatment, and they endeavour to remove patients from care before they have properly recovered. My first private case was that of a man who had been looking down the barrel of a loaded revolver and refusing food for several days. The patient was only fit for an asylum. My advice that he should be sent there was not followed, and he died soon after from starvation and the neglect of his family. Foolish relatives will often introduce penknives, scissors and other dangerous articles into an asylum secretly, which are immediately taken away from the patients if the attendants know their work. It is only by careful and constant supervision that the number of suicides may be reduced to a minimum. A good superintendent will be particularly careful to instruct his staff to lock up all medicines, never to allow patients to handle them and never to serve out more than the exact dose indicated by the label on the bottle. These rules should also be applied to lotions, disinfectants, poisonous plasters (such as belladonna), and more especially to pills, which the attendant must see the patient swallow, or he may hoard up a poisonous quantity and take them all together. Attendants should also exercise every precaution with regard to keys and razors, and any loss of these should be at once reported. Keys must be worn on the person, displayed as little as possible and attached to the attendant's wrist at night should he sleep in the same room as his patient. Knives and forks are only to be used in the presence of an attendant, and are to be carefully counted before and after meals and always kept locked up at other times. Fireirons, and even brooms, are to be secured in the cupboard, and all broken glass and crockery must be immediately removed. All outsiders, such as charwomen, tradespeople, workmen and gardeners, must receive special instructions not to leave dangerous tools and implements about. Suicides from eating arsenical putty and rat poison—taken, for instance, from the coat pocket of a careless attendant—have been more than once recorded. A curious suicide occurred in a public asylum, in which a woman died of peritonitis induced by her having swallowed a quantity of needles and pins. A large proportion of suicides are due to hanging. All objects therefore such as nails, wires, ropes, sash lines, boll pulls, tapes and string must be

removed from the reach of the patients. No parcel should ever be sent into the wards till the string has been removed and the contents examined. I have known even a piece of slate pencil or an old spoon to be used for the purpose of strangulation. By attaching a brace or a handkerchief to one of these, pushing the pencil through the keyhole of a door, pulling it taut and then making a noose, a gallows can be arranged quite as effective as any of the public executioner's more complicated arrangements for a drop. Patients will swallow almost anything. On post-mortem examination I have more than once found a piece of towel with the asylum mark on it in the intestines of a patient. One gentleman under my care swallowed his sleeve-links, which, however, passed through the digestive tract without doing any harm; and I have once seen a patient chew up and swallow an indiarubber utensil, but she recovered ultimately.

In most public asylums many of the inmates are employed at work at the trades they practised before admission. Such patients require constant watching and daily examination. Should they return to their old delusions or to hearing voices, perhaps commanding them to commit suicide or homicide, they must be at once sent back to the dangerous wards of the asylum. In the bookbinders', shoemakers' and tailors' shops patients are entrusted with large sharp knives and heavy hammers, which would prove formidable weapons in the hands of a maniac. The games of the patients should also be appropriate to their mental condition. I have known a male suicidal patient swallow a small billiard ball, which, sticking in his larynx, choked him before assistance could be procured. No suicidal patient should be sent out in the fields with a working party. A patient cut his throat with a hay knife who had attempted suicide only fourteen days previously. No suicidal patient should ever be allowed to go out walking outside the grounds of the asylum. Patients have been known to escape from their attendant and jump over a railway bridge or into a river, or to throw themselves under a passing train. The site for a new asylum should therefore be chosen as far as possible from all such dangers; no ponds should be allowed in the grounds and all water-butts should be securely covered. The internal arrangements also of an asylum are of the utmost importance with regard to this tendency. All doors should open outwards. Windows should be protected by steel bars, which, if painted a light cane colour, have no unpleasant prison-like appearance. The waterclosets must have neither locks nor bolts, but should close with a spring ball which is let into the door. A very common method is for the patient to make an attempt by setting fire to her clothing. It is, therefore, obvious that lucifer matches and all other inflammable materials should be carefully concealed from the insane. All fireplaces in suicidal wards must be protected by properly constructed guards. The taps for turning on gas must be shut up in cupboards, of which only the attendants have the keys, and care should be taken that all rooms in which these patients are lodged should be lighted, both by day and by night, by windows and gas-jets which are quite out of the reach of the inmates. Patients should also be carefully watched at meals. Sometimes they will refuse to take food, or not take enough, or will conceal their food in their stockings, or place it under the stair carpets, or bolt their food ravenously in a dangerous manner. One curious case is reported in which a lunatic endeavoured to commit suicide by plunging his head into a tureen of boiling soup. Attempts at suicide have also been made without the use of any appliance, as by strangling with the hands or thrusting the fingers down the throat.

All single rooms should be constantly inspected if a patient is placed in them. A woman under my care butted at the door of a padded room with her head, raising a large swelling over the frontal region, under the delusion that she was shut up in the cabin of a ship which was sinking, and that the only way to escape drowning was by trying to force the door open with her head. Many suicides take place at night; therefore in any large institution there should always be a night watch on duty, who is to make his round of the wards at regular hours and register the time of his visits to the different stations on the tell-tale clock. The ingenuity of some patients in preparing suicidal or homicidal weapons is worthy of a better cause. Dr. Fritchard Davies has given me a collection of these dangerous instruments, taken from patients at the Broadmoor Criminal Asylum. Amongst these were found a piece of crinoline steel let into a piece of firewood and bound round with string; a quantity of stones tied up in a piece of sacking, and many other curious mis-

<sup>1</sup> A paper read at the West London Medico-Chirurgical Society on Friday, Nov. 4th, 1892.

cellanea. Mr. Lutwidge, the Commissioner in Lunacy, was murdered by a patient with a large nail, sharpened to a point, and thus made into a dagger, the handle of which was composed of pieces of old carpet. Dr. Orange of Broadmoor received a violent blow on the head from a lunatic, who used for his murderous purpose a large stone tied up in a stocking. But, as I before remarked, the relatives are more frequently to blame than are the doctors or the attendants. I was consulted some years ago about a woman who was a victim to melancholia; she was a patient at the St. George's Dispensary, and had marked suicidal tendencies. I suggested that she should be removed to an asylum, as I was most anxious to prevent an accident occurring in the house in which she resided. My advice was not followed, and the next thing I heard was that she had thrown herself from a window, alighted on her head, fractured her skull, and died. A grave omission on the part of the petitioner often occurs when he neglects to put in the statement that the patient is suicidal, if he is so. The deduction from this point is that, if there is any doubt about the matter, all patients should be considered suicidal on admission until the contrary is known. Another frequent cause of suicide is found where the relatives insist on removing the patient from the asylum before he is considered recovered by the authorities. A man was placed under my care suffering from simple melancholia without delusions. The first two doctors refused to certify. The second two found him insane and signed certificates. The patient was strongly suicidal. After a few days' residence in Blacklands Asylum the relatives called and pronounced him recovered, and in spite of all I could say removed him from our care and took him home. That night at supper he cut his throat with a large carving knife and destroyed his life in the presence of his family. Fortunately for myself I had discharged the patient "unimproved," so I just escaped having the suicide entered on my books, which would have happened if I had allowed him to go out on leave of absence, in which case the patient is still attached to the asylum and can be readmitted on the old certificates.

Richmond-terrace, S.W.

## SOME PRACTICAL RESULTS OF THE INVESTIGATION OF CHOLERA IN GERMANY.<sup>1</sup>

BY WILLIAM RUSSELL, M.D., F.R.C.P. EDIN.,  
ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, AND LECTURER ON  
PATHOLOGY IN THE SCHOOL OF MEDICINE, EDINBURGH.

BEFORE the occurrence of the epidemic of Asiatic cholera in Western Europe during the past summer and autumn the importance of the discovery of its probable pathogenic factor can hardly be said to have been actively appreciated or valued. If the discoverer were correct it was only one more stone added to the temple of knowledge; but the discovery was applicable to conditions too remote—too Oriental, in fact—to command homage from the practical Anglo-Saxon. Even before this, however, Koch's discovery of the comma bacillus and the accuracy of his contention that it was the pathogenic organism of Asiatic cholera were accepted by many bacteriologists and pathologists and by some physicians. Still that acceptance might be regarded more as a laboratory belief than a practical faith; and Koch's comma bacillus commanded no special attention in the culture tubes in the laboratory.

In this paper I shall confine myself mainly to the experience of cholera in Berlin, as it was studied there in the Moabit Hospital and in the barracks attached to the Institut für Infektionskrankheiten, which is under the directorship of Professor Koch.

I may mention first a fatal case of cholera nostras recorded by Dr. Guttman,<sup>2</sup> the first fatal case he had, and which occurred in July, before Asiatic cholera was known to exist in Germany. The case is recorded in detail, and its clinical picture closely resembles Asiatic cholera; it was regarded as

a severe case of cholera nostras, as it was a solitary one; the stools were examined and no comma bacilli found. At the necropsy the entire small and large intestine showed the mucous membrane to be in a state of inflammatory redness and swelling. The solitary follicles and Peyer's patches, however, were mostly free, although some were a little swollen. This comparative freedom of the glands from the inflammatory process he regards as anatomical evidence that the case was not Asiatic cholera, with the proviso, however, that when cholera patients die in the stage of cholera-typhoid death may be so long delayed that the inflammatory swelling of the mucous membrane and the follicles may have considerably subsided. The degree and extent to which the colon shared in the inflammatory process is also against the case having been Asiatic cholera. He lays much stress upon the enlargement of the follicles, especially in the lower part of the ileum, in Asiatic cholera, as a fact which he noted in the epidemic of 1866, and which was confirmed by the necropsies of the more recent cases.

I shall now refer to some of the statistics of the Moabit Hospital from Aug. 24th.<sup>3</sup> There were admitted thirty cases of Asiatic cholera, of which fifteen died—two cases were brought in dead and were shown by necropsy and bacteriological investigation to belong to this group; fifty-four cases of cholera nostras, none of which died; 153 cases of diarrhoea, of which one died, and eighty-eight cases sent in to be under observation, of which none died. As regards diagnosis, Dr. Guttman says the severe cases are easy of recognition, although the severe case of cholera nostras already referred to and a case of antipyrin poisoning which he had markedly resembled severe Asiatic cholera. With regard to the mild cases his experience was the reverse of this, and amongst the thirty cases there were five such. Some of these had a very suggestive history. Persons taken into hospital and placed in the observation wards because they had been in contact with cholera patients had after admission slight diarrhoea, and the stools, examined bacteriologically, showed the presence of comma bacilli. The prevalence of diarrhoea during and often preceding the appearance of an epidemic of Asiatic cholera is well enough known, and both in this country and elsewhere many of the cases occurring at such a time are spoken of as choleraic diarrhoea. Now, while it may have been shrewdly suspected that some of this class of case when accompanying an epidemic of Asiatic cholera were really mild cases of that disease, or, at all events, were the result of the reception of the cholera poison under conditions referable to the quality of the poison or the resisting power of the individual, still, this was only a "pious opinion," for no proof was possible. Further, it has been noted that many cases of cholera nostras have a more severe onset than mild cases of undoubted Asiatic cholera, and may be mistaken for it. From this, which is the clinical standpoint, there was no escape. Clinical medicine could go no further. Its impotence was manifest. At the Moabit Hospital, with abundant material, a capable staff, and great enthusiasm in the work, they had concluded that the bacteriological investigation of the stools separated and differentiated the cases. Out of some hundreds of cases of cholera nostras and diarrhoea they had examined fifty-one, and in not one of these was the comma bacillus found, or Finkler-Prior's bacillus. The bearing of this practical conclusion from the work of this hospital alone, the work being done as it was, is of the greatest importance and value, as it seems to me. Additional observations from many places may be added to it, and mayhap contradictory evidence may be forthcoming, but the results of investigation at this one spot, under the conditions referred to, can hardly be other than the illustration of a fact broadly applicable. If this be the case, the identification of mild cases of Asiatic cholera becomes of the greatest moment. In illustration of this I may refer to the facts of a case admitted into the cholera wards at Koch's Institute a day or two before I left Berlin, and which have since been published by Dr. Kossel. The case turned out to be one of Asiatic cholera, yet for some days before admission the patient, a man, suffered from diarrhoea, and had deposited his excrement in the water-courses, in quiet nooks in the Thier-Garten, and at whatever spot was most convenient when the calls of nature became imperative.

If we now look at the results from Koch's Institute, there were fifty-two cases of suspected cholera admitted into the barracks there; two were cases of Asiatic cholera. The

<sup>1</sup> A paper read at the Medico-Chirurgical Society of Edinburgh on Nov. 2nd, 1892.

<sup>2</sup> Berliner Klinische Wochenschrift, 1892, No. 41.

<sup>3</sup> Deutch. Med. Wochenschr., 1892, No. 41.

clinical experience here was the same as at the Moabit—namely, that severe cases of cholera nostras were clinically identical with mild cases of Asiatic cholera, and that they could only be separated by bacteriological investigation. An important part of the work done in this laboratory was the examination of intestinal discharges and of soiled clothing sent from other places. According to Dr. Kossel's published figures,<sup>4</sup> forty-two such were examined, and of these nineteen gave the comma bacillus by culture. Faecal matter and clothing were often received after having been treated with antiseptics, which of course prevented their thorough examination. I have seen there the most perfect cover-glass preparations of comma bacilli taken from the faecal soiled clothing sent to the laboratory.

With reference to the investigation of the intestinal discharges I may say a word. The presence of comma bacilli may be demonstrated by cover-glass preparations made from the discharges, but this is not accepted as sufficient; plate cultures are made, and on these the characteristic colonies of Koch's comma bacillus are distinguishable under a low power in about twenty-four hours or even less, and, if further proof is required, stab-cultures can be made from the colonies and the changes effected in the nutrient gelatine followed. (These were demonstrated to the Society.) The length of time during which the comma bacillus was present in the discharges was followed in a small number of cases in the Moabit Hospital, with results varying from five to ten days. At Koch's Institute the number of Asiatic cases was too small to base any conclusion upon, but when I was there every motion passed by the Asiatic cases was examined by plate cultures.

With reference to Hamburg, which I also visited, the impression I got was that there had been too many patients to attend to for the staff to spare much time for bacteriological investigation; still, there they told me they had always found the comma bacillus. The experience gained and the observations made in Hamburg will, I trust, be published. One of the assistants at the Eppendorf Hospital had made five hundred necropsies on cholera cases by the time I was there, and such a series of cases could not fail to add to our knowledge even as regards naked-eye appearances.

A word or two may be said with reference to treatment. At the Moabit they tried salol and creolin and vamin injections with no satisfactory result. Calomel was used both in Berlin and in Hamburg, but I am not in a position to speak of the results. What impressed me most at the Moabit, in the old general hospital at Hamburg, and in the new one at Eppendorf was the reliance the staff had on saline injections, and the confidence with which they spoke of them and the absence of risk which attended the operations. At the Moabit Hospital Dr. Guttman believed strongly in the subcutaneous introduction of the saline fluid, in Koch's they believed in its intravenous introduction, and in Hamburg I think they had used both methods. The apparatus used was an exceedingly simple one, but great care was taken to have everything properly sterilised. It is needless for me, to dwell upon the practical significance of the acceptance of Koch's comma bacillus as the cause of Asiatic cholera—it has made the disease a more tangible and comprehensible entity; it has shown how water, food, and clothing are infected and become the vehicles for spreading the disease; and in doing so has shown how it is possible to check and to arrest it, and, best of all, to prevent it. With Europe threatened by such a plague we place a higher value on this portion of Koch's work, and we place it amongst the great discoveries.

Edinburgh.

<sup>4</sup> *Ibid.*

**PREVENTION OF CHOLERA.**—At the Thames Police court this week a captain in the employ of the General Steam Navigation Company was summoned at the instance of Dr. Collingridge, medical officer to the Port of London, for wilfully neglecting to carry out certain of the cholera regulations provided by the Public Health Acts. Dr. Herbert Williams gave evidence in support of the charge. Mr. Gill represented the defendant and said the company were very anxious in every way to carry out the Order in Council, but thought an attempt was being made to saddle their captains with responsibilities they were not bound to undertake, and therefore the time had come to offer resistance. The magistrate said the case was not free from difficulties; yet, having allowed the passengers to land, the captain had taken full responsibility for the consequence, and would be fined £25 and costs.

By J. D. WINDLE, L.R.C.P.I., L.M. DUB., M.R.C.S.

DR. PLAYFAIR, in his work on Midwifery,<sup>1</sup> quoting Dr. Braxton Hicks's paper in the Obstetrical Transactions,<sup>2</sup> states that "intermittent contractions of the uterus are constant and normal concomitants of pregnancy, continuing during the whole period of utero gestation. The contractions occur every five or ten minutes, sometimes oftener, but rarely at longer intervals. If the hand be kept steadily on the uterus its alternate hardening and relaxation can be appreciated with the greatest ease."

The following case illustrates the fact that these contractions are not, as is usually the case, always painless; indeed, in some instances that have come under my notice the contractions have been such as would lead one to infer that premature labour was about to take place. The first case of this kind I have noticed occurred about three years ago, when I was consulted by a woman in the seventh month of pregnancy for what she described as "cramp in the stomach," and from which she had suffered more or less for some time. Suspecting premature labour was about to occur I visited her at her home, when on palpating the abdomen I found the uterus contracted, and from this I concluded that labour had commenced. The pains continued for about two months, more or less modified by treatment up to the time of actual labour at full term. I may mention that my patient was in good health and that her previous pregnancies had been normal. Remembering the fact of the occurrence of painless intermitting contractions, I concluded that the case was a modified form of the normal state of things—viz., painful instead of painless contractions. Before the termination of pregnancy I had many opportunities of verifying the opinion I had formed. In this and subsequent cases, so far as I could make out, the contractions had no effect on the os or cervix, but the membranes became somewhat, but not markedly, tense. Since then I have noticed many similar cases, but in only one where the painful character of the contractions continued for any considerable period. In this case, also a multipara, they occurred regularly from Jan. 27th, 1892, to Feb. 15th, during which time I visited her every day. Delivery took place on March 2nd. It is a very common experience to meet with cases of threatened abortion and early miscarriages where pains constitute the only symptom, but which subside after a time without anything being expelled from the uterus, and for labour to take place at the full term of utero-gestation. I believe that many of these cases are examples of the painful instead of the normal painless intermitting contractions of pregnancy. If such be the case we have an explanation of the fact that it is rare for abortion or miscarriage to occur when pain is the only symptom.

#### A CASE OF DOUBLE INTUSSUSCEPTION.

By DUNCAN J. CADDY, M.B.

A FEMALE infant aged five months had a very severe fall on Friday, Nov. 21st, 1892. A few hours afterwards she began screaming loudly and appeared to be suffering great pain. The parents administered a powder and afterwards a dose of castor oil, with the result that the infant vomited freely, but nothing was passed per rectum. Next day the child still appeared to be in pain, but took a little milk, and the parents again administered an aperient powder. This caused more vomiting, but still no action of the bowels. On Sunday the child became cold and appeared very ill. On Monday at 8 A.M. the child, after much straining, passed a little bloody mucus per rectum and I was sent for. On arrival I found the child in a state of

collapse, the skin was bathed in a cold sweat and the eyes sunken. The abdomen was tympanic, the pulse 200, the temperature 103.5° F., and the infant was vomiting stercoraceous matter. Examination per rectum revealed nothing. Upon palpating the abdomen, however, a short, thick, sausage-shaped tumour could be distinguished over the cæcum. It was clearly a case of intussusception, and the child died four hours later. The post-mortem examination revealed an ileo-cæcal intussusception about four inches in length, which had again become invaginated in the bowel further on, thus forming five complete layers. It is only for me to add that the child was well nourished and otherwise healthy, and that, the symptoms setting in almost immediately after the fall, it would appear as though this must have had some direct influence in causing the double intussusception; but I leave this for the consideration of others more experienced than myself.

#### HÆMATOMA AURIS.

By E. ROUSE ROUSE, M.R.C.S., L.R.C.P. LOND. &c.,  
ASSISTANT MEDICAL OFFICER, COLNEY HATCH ASYLUM.

HAVING collected a few notes on hæmatoma auris or insane ear, I should be glad of their publication in THE LANCET, in the hope that they may be of some interest to medical men, especially those connected with lunacy. I will first take into consideration the class of case in which the insane ear is most common. I think that cases of acute mania and general paralytics in the maniacal stage produce most examples of this class; those of chronic mania with recurrent attacks are also at times sufferers. As to which ear is oftenest affected my own observations differ from most observers, in the fact that the right ear has been most often diseased. If this is really the case, the theory that the flow of blood from the heart to the left side is more direct, and that there are fewer ramifications of the branches of the carotid arteries on the left side, will not hold good, as it is, I believe, generally known that the arteries on the right side anastomose much more freely. The cause of the swelling of the ear or ears is often very difficult to elicit, but I have little doubt that violence of some kind is the usual cause, and this need only be a slight rub or knock to produce the swelling. As an element in prognosis it is very valuable, as no doubt cases in which it occurs generally, but not always, end fatally; this is especially the case in double insane ear. I have also noticed that a fatal termination is much more rapid in these than in other cases. The treatment by blistering is no doubt very valuable in many patients, but I have seen several upon whom it has had little effect either in decreasing the swelling or preventing the after disfigurement. Again, is the disease so uncommon in sane people as is generally believed? My own experience teaches me that it is not, as amongst athletes, especially football players of the Rugby game and boxing men, it is fairly common. I know eight cases in which it occurred; in one the patient had the remains of double insane ear. This also, I think, will assist to prove that violence in some form is the most common cause, as undoubtedly in athletes the swellings can be traced to a blow or rub of some sort. I have not been able in some to discover the degeneration of the arteries which has been stated to so frequently occur, but no doubt this is very often seen, and the rupture of these degenerated vessels is the immediate cause of the swelling. In conclusion I may say that patients of the upper classes are more prone to the disease than the lower classes, at least we generally see many more cases in private asylums than county asylums; but the cause of this is difficult to understand, and perhaps many with more experience than myself will doubt this last assertion.

Colney-hatch, N.

#### METHOD OF FIXING PATIENTS FOR OPERATIONS UNDER ANÆSTHESIA IN THE SITTING POSTURE.

By DUNDAS GRANT, M.A., M.D., F.R.C.S. ENG.

FOR many of the shorter operations on the mouth, throat, nose and ear it is very desirable to have the patient in the position in relation to light, attitude &c., in which examinations are habitually made. At the same time the sitting posture has many inconveniences for the administra-

tion of anæsthetics, and chloroform is practically inadmissible. Ether, however, as Dr. Silk has said, may be given with comparative security, and nitrous oxide without any anxiety whatever. Several years ago I demonstrated at the Central London Throat and Ear Hospital the possibility of removal of tonsils or adenoids, or even both, during the administration of nitrous oxide, and my colleagues were not slow in adopting a practice which in that institution has now become a matter of daily routine. Hitherto one great difficulty has been the tendency of the patient to slip off the chair at the moment when the anæsthesia becomes complete, and to have recovered consciousness by the time he is "collected" and propped up again. To prevent this accident the following simple method of fixation is recommended. A short jack-towel with the seam unstitched is placed round the back of the patient's neck like a priest's stole, with the ends hanging down in front. Each of these ends has firmly attached to it about two feet of soft, thick cord or thin rope. He is then seated on a chair which has a very narrow, high back, on the posterior surface of which, and at about the height of the patient's head, there is a stout upright hook. The middle of the jack-towel is raised off the patient's neck, lifted over the back of the chair and laid on the hook. The two ends are then brought backwards under the armpits and round the back of the chair. The ropes are then crossed over the hook and tied in a bow. The patient is thus simply, securely and "unalarmlingly" fixed so that he cannot slip down. A band may be placed round the forehead to keep the head fixed, but this is most effectively and pleasantly done by the hands of some one standing behind. At the same time the patient can be instantly released by the simple pulling of the ends of the ropes forming the bow.

#### SUDDEN DEATH, WITH NECROPSY, SHOWING RUPTURE IN THE INTERNAL ILIAC ARTERY.

By J. A. EWAN, M.B. EDIN.

THIS case is interesting not only in itself, but also because it well illustrates the importance of holding a post-mortem examination in every case of sudden death before granting a certificate.

A man aged fifty-three was a patient in the Dorset County Asylum for twenty-two days, and previously for two months in the County Hospital. On admission into the asylum his case was at once diagnosed as one of general paralysis, with absolute dementia, tottering gait &c. For some days there was no change in his condition, but on the eighth day he had a series of epileptiform convulsions, which continued until the following morning. After these convulsions ceased he was in a very helpless state, but they did not return until the evening of the twenty-first day, when they again commenced and continued until three o'clock in the morning of the twenty-second day. At a quarter to four his breathing suddenly became stertorous and a quarter of an hour afterwards he was dead. Post mortem were found in the head, as was expected, the usual changes that occur in general paralysis—thickened and adherent membranes, cerebral degeneration &c. and atheromatous arteries. The thoracic and abdominal organs were fairly healthy, but on turning aside the small intestines a large mass of clotted blood was discovered lying in front of the psoas muscle. This clot was carefully removed, and on further examination there was found a rupture of the internal iliac artery close to where it gives off its ilio-lumbar branch. This, then, and not any cerebral lesion, was the immediate cause of death.

Dorset County Asylum.

**METROPOLITAN ASYLUMS BOARD.**—The number of patients in the various hospitals of the Metropolitan Asylums Board at midnight on Nov. 29th was as follows:—Eastern Hospital, 363 scarlet fever, 61 diphtheria and 39 enteric fever; North-Eastern Hospital, 554 scarlet fever; North-Western Hospital, 314 scarlet fever, 82 diphtheria and 23 enteric fever; Western Hospital, 291 scarlet fever, 31 diphtheria, 1 typhus fever and 16 enteric fever; South-Western Hospital, 285 scarlet fever, 59 diphtheria and 24 enteric fever; South-Eastern Hospital, 366 scarlet fever, 19 diphtheria and 16 enteric fever; Northern Hospital, 856 scarlet fever and 12 diphtheria; Gore Farm Hospital, 786 scarlet fever. On the hospital ship *Atlas* there were 16 cases of small-pox.

#### ROYAL FREE HOSPITAL.

##### A CASE OF CHRONIC PYÆMIA; RECOVERY.

(Under the care of Mr. BOYCE BARROW.)

THROUGHOUT the course of the disease from which this patient suffered there was an absence of the more characteristic symptoms: there was no marked sweating, there were no rigors, gastro-intestinal symptoms were absent, and the temperature was at no period of his long stay in hospital remarkable for its irregularity or unusual height. Yet the abscesses in the chest and neck were without doubt pyæmic; this was shown by their number, the rapidity of their appearance, and the slight local disturbance. The point of interest in the case is whether they were secondary to the disease in the thigh, or whether (this being also pyæmic) they were in any way connected with the thrombosis resulting from the typhoid fever. The abscesses appeared over the sternum ten weeks before any pain was felt in the right thigh, and the fact that the œdema and pain reappeared in the left leg very shortly after the abscesses would suggest that the thrombus may have commenced to extend or break down. The chief point against any causal connexion between the thrombosis and the pyæmia is the great interval which elapsed (more than eighteen months) between the convalescence from the thrombosis and the commencement of the pyæmia. For the notes of the case we are indebted to Mr. Wilmott H. Evans, B.Sc., surgical registrar.

A wheelwright aged twenty-five was admitted into the Royal Free Hospital on April 27th, 1892. In June, 1890, he was in the hospital under Dr. Sainsbury for typhoid fever, during the course of which the left popliteal and the lower part of the femoral vein became thrombosed, causing pain in the calf and œdema of the leg. Since then he has been quite well until about six weeks before admission (March 10th), when he noticed two small, rounded swellings, one over the upper border of the sternum, a little to the right of the middle line, and the other immediately above the left clavicle at the outer border of the sterno-mastoid. These both increased in size, especially the one over the sternum, and a fortnight later the larger swelling was incised and a quantity of thin, yellow matter escaped. About the same time his left foot began to swell, especially after walking, but the swelling disappeared to a great extent when he lay down. Ten days before admission a third swelling appeared over the left side of the upper part of the sternum, and on the morning of the day on which he entered the hospital a fourth swelling, smaller than the others, appeared in the posterior triangle of the right side. From none of the swellings has he suffered any pain or inconvenience.

On admission the patient was found to be a strong, healthy-looking man. Nothing abnormal could be discovered in the thoracic or abdominal organs. Over the upper border of the sternum was a sinus from which sanious pus was oozing. A probe was passed backwards for nearly an inch, but no bare bone could be felt. Over the upper piece of the sternum, a little to the left, was a rounded swelling about an inch in diameter. The skin over it remained unaltered in appearance. Somewhat doubtful fluctuation could be obtained. A similar smaller swelling was found at the lower part of the posterior triangle of both sides. The left leg below the knee was somewhat swollen and slightly painful, and the hard cord caused by the thrombosed popliteal vein could still be felt. The superficial veins of the thigh were dilated. The family history was unimportant, and up to the attack of typhoid fever in 1890 the patient had always had good health. After admission he continued in the same condition, except that the sinus continued to discharge and the swelling increased in size. The temperature varied from 98° to 102° F.

On May 5th the swelling to the left of the sternum was aspirated and about a drachm of pus removed. On May 7th

the patient was anaesthetised, and Mr. Barrow made an incision over the swelling in the front of the sternum and evacuated thin pus; the cavity was found to extend backwards between the second and third ribs, but no bare bone was to be felt; the cavity was scraped out with a Volkmann's spoon. The swelling in the left posterior triangle was treated similarly, and the sinus remaining from the former incision was also scraped. The three cavities were then filled with gauze soaked in an emulsion of iodoform and glycerine, and a dressing of carbolic gauze was applied. The cavities were syringed out daily with solution of perchloride of mercury and filled with iodoform and glycerine gauze. After the operation the temperature somewhat improved, but still occasionally went up to 101°. By May 26th he had so much improved—the discharge from the sinuses being very little and the left leg less swollen—that he was allowed to get up. He had slight stiffness over the right thigh. By June 10th the two smaller cavities had healed up and only a little pus still escaped from the sinus to the left of the sternum. The small swelling in the right posterior triangle had steadily increased in size and another swelling had appeared superficially to the right sterno-mastoid.

June 23rd.—The stiffness in the right thigh, mentioned on May 26th, has steadily increased, and he feels an aching there on walking, so he has been kept in bed. On examination a swelling was found, beginning a little above the level of the great trochanter and extending downwards for five inches; fluctuation can be obtained over it, but there is no redness. The sinus to the left of the sternum has almost healed.

25th.—The patient being under an anaesthetic, an incision four inches long was made over the swelling on the thigh and about three ounces of creamy pus escaped. On introducing the finger a hole one-third of an inch in diameter was felt in the bone just below the anterior superior iliac crest; a small sequestrum was removed and the softened bone around it was scraped with a Volkmann's spoon and a gouge. The whole abscess cavity was well scraped and dressed with a paste of iodoform, boracic acid and glycerine, and plugged with iodoform glycerine gauze. The wound was dressed daily in a similar manner and diminished in depth.

July 18th.—The wound on the thigh has partly healed, but still has some discharge; the sinus over the sternum is almost healed, but a little pus escapes; the swellings on the right side of the neck are slowly enlarging, and fluctuation can be obtained in each of them.

Aug. 10th.—The swellings on the right side of the neck were still increasing in size, so under an anaesthetic they were both incised, the pus evacuated and the cavities scraped; the sinus over the sternum was also scraped, and they were all plugged with iodoform and glycerine gauze. The wounds in the neck and on the thigh slowly diminished in depth, and by Sept. 27th they were quite healed, and on Oct. 1st the patient was discharged well.

#### ROYAL PORTSMOUTH HOSPITAL.

##### A CASE OF HYDATIDS OF THE LIVER; RECOVERY.

(Under the care of Dr. JAMES WATSON.)

THE following case of multiple hydatids of the liver shows the advantage of paracentesis as a means both of diagnosis and cure when suppuration has not occurred in the cyst. It is evident from the description of the case that some of the cysts disappeared after the withdrawal of a quantity of fluid, and there is a general feeling in the profession that this method should be tried before incision is attempted. "Incision should be made use of when tapping fails, where scolices instead of fluid form the greater part of the contents of the cyst, where suppuration is present or imminent, and where chest complications are set up by the hydatid, showing perhaps a risk of perforation."<sup>1</sup> Although this disease is more frequently met with at a late period of life, its occurrence in children is not very rare, and it has been met with at three and a half and four years of age. The following report is drawn up from notes made by Mr. T. H. Bishop, house surgeon.

A poor, delicate female child aged twelve was admitted to hospital on Aug. 23rd, 1891, suffering from abdominal enlargement, with occasional attacks of griping pain and constipation. On examination the liver was found to occupy

<sup>1</sup> Jackson: The Operations of Surgery, THE LANCET, vol. ii. 1881, p. 747.

the whole of the right hypochondrium, as well as the greater part of the left hypochondriac and epigastric regions. The measurements were as follows: On the right side it extended from the lower border of the fourth rib to half an inch below the level of the umbilicus, while on the left side it almost reached the level of the umbilicus. Fluctuation could be detected in the left lobe. The stomach resonance was absent. The urine was normal, and the heart and lungs were free from disease. On Sept. 2nd Dr. Watson requested Dr. Ward Cousins to make an exploratory puncture into the liver slightly above and to the left of the umbilicus. Two ounces of deeply bile-stained fluid were drawn off. This was found on examination to contain pus cells and a considerable amount of bile salts. Two days later ten ounces of similar fluid were withdrawn from the same spot. Next day the right lobe was aspirated by Dr. Cousins and two ounces of clear, limpid fluid withdrawn. This fluid had a specific gravity of 1007, was free from albumen and rich in chloride of sodium. No hooklets could be detected in it. From another puncture in the right lobe another two ounces of clear fluid were withdrawn. On Oct. 7th, the left lobe being distinctly larger than on admission, Dr. Cousins was requested to operate. He made an incision exposing the liver three inches in length in the epigastric region and to the left of the median line. The liver was stitched to the parietes and a trocar inserted. About a pint of bile-stained pus was withdrawn and a similar fluid continued to discharge for many days after. In November, however, the opening having almost closed and ceased to discharge, and the child's temperature having risen considerably, Dr. Cousins was asked to reopen the wound. This was done on Nov. 14th. The chloroform administered made the child very sick, and fortunately the efforts of retching had the effect of protruding the cyst wall through the opening, each effort bringing it further out. Assisted by gentle traction, the cyst wall was in this way completely evacuated. From this date the child improved rapidly, although healthy pus was withdrawn from the wound for some weeks, the last evacuation being made on Feb. 20th, when about four ounces of healthy pus were drawn off with a trocar. On April 10th the child was discharged, looking and feeling quite well and healthy. The liver was still somewhat large, though considerably smaller than on admission.

*Remarks by Dr. WATSON.*—There can be no doubt this case was one of hydatids, for although no hooklets were found in the fluid, we know that they are frequently absent from such tumours, and it has been generally accepted, as was pointed out by Fagge, that a tumour which is "distinctly cystic and embedded in the substance of the liver can be nothing but a hydatid." Again, there were, besides the suppurating cyst, the two others filled with clear non-albuminous fluid, rich in chloride of sodium, which is also distinctive of hydatids. The result was a satisfactory one, although it was attained after a somewhat prolonged treatment. If I had a similar case again I would avoid the frequent tapings practised in this instance, and, in the event of finding a cyst filled with pus, should recommend that hepato-tomy be at once performed, and, where the cyst was filled with clear fluid, rely upon aspiration.

## Medical Societies.

### MEDICAL SOCIETY OF LONDON.

#### *Athletic Exercises as a Cause of Disease of the Heart and Aorta—Selection of Methods of Treatment in Haemorrhoids.*

AN ordinary meeting of this Society was held on Nov. 28th, Mr. Hutchinson, President, in the chair.

Dr. COLLIER, of Oxford, read a paper on Athletic Exercises as a Cause of Diseases of the Heart and Arteries. He desired to direct attention to the growing tendency on the part of young Englishmen to indulge in certain athletic exercises to an extent likely to prove harmful. He referred to the connexion between oft repeated muscular effort and diseases of the heart, pointed out by Dr. Peacock, as observed in Cornish miners. In these men the symptoms began to develop at about the age of forty with slight dyspnoea and palpitation gradually increasing in severity. The pathological changes observed were dilatation and hypertrophy of the ventricles, with, in a certain proportion, incompetence of the aortic valves. He also

referred to the researches of Dr. Clifford Allbutt contained in the St. George's Hospital Reports for 1870, in respect of the same causes operating in the forges, docks, and engine ring works of Leeds. The lesions developed soon in the badly fed; the aortic lesions being the most pronounced. Dilatation of the aorta increased the work of the heart by rendering necessary the propulsion of a larger quantity of blood, and the distension increased until incompetence resulted. Other observations on the production of "irritable heart" in soldiers had appeared in the *American Journal of Medical Sciences*, by Dr. Da Costa, of Philadelphia. This condition under forced marches frequently renders the men unfit for service. The same sequence of events had often been observed in animals, such as racehorses, greyhounds and foxhounds. The evidence, then, was conclusive as to the effect of frequently repeated muscular exertion in the production of heart disease. Dr. Morgan's researches on the after history of the oarsmen in the Oxford and Cambridge boat-races between the years 1829 and 1869 comprised 251 out of 255 still living, and he came to the conclusion that the majority were rather benefited than otherwise by their exertions. It must, however, be borne in mind that these researches bore upon picked and carefully trained men. Dr. Collier admitted that the medical men of university cities were not likely to see much of the evil effects of such sports, inasmuch as they usually developed later in life. Boating, moreover, appeared to entail less risk than either running or cycling, and he insisted upon the fact that it was in the frequent repetition of severe muscular effort that the danger lay. The practice of riding against time is considered to be particularly pernicious, in support of which he quoted a number of instances of resulting circulatory lesions. He had had opportunities of observing symptoms pointing to dilatation of the right ventricle in rowing, running and football adepts, but such symptoms occurred exclusively among badly-developed, narrow-chested, weakly men. The physiologically dilated and hypertrophied hearts of trained athletes underwent certain changes in the direction of atrophy of the muscular substance, which later on rendered the persons unable to cope with sudden extra strains.—Dr. SANSON remarked that no symptoms of circulatory disturbance could be observed in many athletes, who nevertheless showed evidence of hypertrophy of the left ventricle. In coming to a conclusion whether this hypertrophy was to be regarded as physiological or pathological, the muscular development of the subject must be taken into consideration; when a large muscular system was associated with a large heart he was disposed to regard the condition as normal. He had, however, examined athletes who showed signs of dilatation of the right heart, while in others there was evidence of disturbance of cardiac innervation. He had seen a number of cases of tachycardia which were to be directly attributed to over-strain from racing on cycles against time. The condition might last for years, and structural disease of the heart had supervened. Under certain circumstances the delicate cardiac endothelium might develop a distinct endocarditis as the result of over-strain. Staff-Surgeon Preston, R.N., had pointed out the striking diminution in cases of disease of the heart and great vessels since the introduction of steam which had enabled the men to dispense with much of the heavy manipulation of sails and climbing of masts formerly necessary. During the ten years ending 1884 the ratio per 1000 of organic and functional diseases of the heart had fallen from 7.94 to 5.3; while the invalid ratio had been reduced from 3.9 to 2.9 per 1000. This was unaccompanied by a corresponding improvement in the land marines, thus showing that the reduction in the navy was due to labour-saving appliances. Syphilitic subjects were always the first to give way under exertion, and he believed that a man who had had syphilis ought to abstain from athletics altogether.—Brigade-Surgeon HAMILTON said that aneurysm had become rarer among soldiers of late years, but since the introduction of quick manœuvres the "irritable heart" had become far more common; it had also been produced in the cavalry by riding without stirrups. He regarded a man with secondary syphilis as practically incapacitated from service. Functional disorganisation of the heart was also materially contributed to by the abuse of tobacco and alcohol.—The PRESIDENT did not take such a gloomy view as to the results of syphilis. For treatment he much preferred small doses of mercury, which was much superior to prolonged administration of iodide of potassium, which undoubtedly had a most depressing effect on the muscular system.—Dr. COLLIER, in reply, said that the undergraduates of Oxford

did not often expose themselves to the risk of contracting syphilis. He agreed that when athletic exercises were abandoned the retrograde changes that took place in the heart were liable to render that organ unable to cope with sudden strain.

Mr. HERBERT ALINGHAM read a paper on Hæmorrhoids, and insisted on the importance of recognising their varieties as determining the selection of treatment. He classed them as external, internal and intero-external. Internal hæmorrhoids he further divided into venous, arterial and capillary. He described the appropriate treatment in each variety, and expressed his preference for the method of surgical treatment by incision.—The PRESIDENT said that his experience confirmed his preference for Salmon's operation. He always thoroughly dilated the sphincter and so as to obviate pain after operation.—Mr. SWINFORD EDWARDS did not believe that medicinal treatment benefited external piles: he was in the habit of removing them if they caused annoyance. The most important thing was, not the nature, but the amount of discomfort which the piles caused. If time were an object the crushing operation was the best, as the patient could be up and about in a week. He had treated about 120 cases by injecting them with a five or ten per cent. solution of carbolic acid in glycerine. Excellent results followed in cases in which the piles were reducible and could be kept up.—Mr. BIDWELL advocated the operation introduced by Mr. Whitehead.—Mr. SHEILD referred to the importance of transfixing the pile when it was being ligatured so as to prevent slipping of the ligature when the pile was removed.—The PRESIDENT added that he never found it necessary to cut off the pile after applying the ligature.—Mr. KEBLEY opposed Whitehead's operation as being an expense of time to the surgeon and of blood to the patient, without any compensating advantage.

### CLINICAL SOCIETY OF LONDON.

*Rhythmical Rocking Movements in Children.*—*Extensive Fracture of Superior Maxilla.*—*Pernicious Anæmia.*—*Cranial Cyst.*—*Movable Body in Elbow-joint.*—*Congenital Angulation of Forearm.*—*Extensive Unilateral Nævus.*—*Pancreatic Cyst.*—*Excision of Cancerous Stricture of Small Intestine.*

A "CLINICAL" meeting of this Society was held on Nov. 25th, the President, Sir Dyce Duckworth, in the chair.

Dr. HADDEN exhibited two cases of Rhythmical Rocking Movements in Children. One was an intelligent little girl aged three years and nine months, who had swaying movements of the trunk and lower limbs when standing or walking. They were not present on lying down. The movements dated from the age of one year, when the child was observed to move the body from side to side when the piano was played, apparently keeping time. She had a good ear for music. The second was the case of an intelligent female child aged one year and nine months, who had rhythmical movements of alternate flexion and extension of the lower part of the spine, with flexion and extension at the hips and knee-joints. The movements had been observed for five months, and no cause for them could be ascertained. They were only observed when the child was sitting down.

Mr. STORER BENNETT exhibited a youth aged nineteen, who was admitted into the Middlesex Hospital in July last, under the care of Mr. Henry Morris, with an injury to his face caused by the explosion of a portable fire-engine. There was an extensive fracture of the right superior maxilla, which was partly detached and displaced in a direction downwards and inwards. He contrived a vulcanite splint which reduced the dislocation, and the movements of the lower jaw in biting had gradually driven the teeth of the upper jaw into their proper place.

Dr. F. R. WALTERS showed a man aged fifty, a smith, who worked with "delta metal," who was suffering from Pernicious Anæmia. The metal, a mixture of zinc, copper and iron, was believed not to contain lead. The patient had suffered from malaria in Mexico in 1889. He now had extreme weakness and pallor, with shortness of breath, puffiness of face, and swelling of legs and vomiting. There was a blue line on the gums, but no colic or dropped wrist, no enlargement of spleen or lymphatic glands, and no pain. There were some retinal hæmorrhages and a diminution in the number of red corpuscles, though the white corpuscles were not altered in number. The red discs, in addition, showed

evidence of degeneration. He had been treated since the beginning of October with Fowler's solution in doses of from six to twelve minims, but with only very slight improvement.

Dr. NEWTON FITT and Mr. ARBUTHNOT LANE showed a man aged forty-two with a Cyst in the Right Parietal Region which had been noticed for a year. It had ruptured and was found to lead through the bone by an aperture about two inches in diameter. Before the fluid was evacuated from it pulsation was transmitted from the brain. There was a history of an accident some years before, and it was suggested that the injury had led to hæmorrhage between the dura mater and the bone, which had been followed by erosion of the latter. It was proposed that the cyst should be drained and occluded and bone grafts planted in the aperture. The contents of the cyst were like ordinary serum.

Mr. L. A. DUNN showed a boy aged seven who had a Piece of Loose Bone in his Elbow-joint. He fell down and injured the elbow three years previously. The part separated seemed to be the capitellum of the humerus, which had become loosely attached to the head of the radius.

Dr. FLETCHER LITTLE showed a man aged fifty-four, a greengrocer by trade, with a Congenital Defect of the Right Forearm, which had undergone intra-uterine amputation at the wrist. The sternum was also malformed, being grooved at its centre, diminished in length, and the gladiolus pressed backwards. The pectoralis major on the right side was imperfectly developed.

Dr. LITTLE also showed a girl aged eleven who was born with a very extensive Nævus of the whole of the right side of the body. The right arm and leg were longer than the left and the surface temperature of the right side was higher.

Mr. HULKE read a paper on a case of Pancreatic Cyst treated by exploratory laparotomy with a fatal result. An abdominal tumour was known to have existed since girlhood—so long, indeed, that the patient, a lady aged forty-seven, could not remember the time when first it was noticed. In December, 1878, when she entered the Middlesex Hospital, the tumour filled the central region of the abdomen from the top of the ensiform cartilage to the pubes. It seemed to be very fixed. Fluctuation could not be elicited. Latterly the patient, who had long been an invalid, had become greatly reduced by attacks of severe abdominal pain, with obstinate vomiting and constipation. At a consultation of the staff the preponderant opinion inclined to the idea of the tumour being ovarian, and an exploratory laparotomy was decided on. This was done. The tumour was found to be wholly retro-peritoneal in position. Its upper border was overlaid by the pancreas, which was firmly adherent to it, and below this by a large artery and vein (splenic?); also sagittally, its front was covered by vessels (superior mesenteric?); whilst its lower border was transversely overlapped by a piece of small intestine bound to it by an extension of the peritoneum covering the front of the tumour. An attempt to enucleate the tumour had to be abandoned in consequence of the firmness of its posterior adhesions over the aorta and vena cava. The swelling was tapped; much brown, glairy fluid was evacuated, and the opening in the cyst was secured to the tegumental lips of the abdominal wound. Death followed a few hours later from shock. A necropsy was forbidden by the friends, but the anatomical relations ascertained by the exploratory operation did not, Mr. Hulke submitted, allow of any doubt of the pancreatic origin of the tumour.—Dr. SHARKEY referred to a case recently operated on by Mr. Clutton. The woman was thirty-five years of age and there had been a history of a tumour on the left side for sixteen or twenty years. Two years ago Dr. Cullingworth explored it with a needle and some albuminous fluid was withdrawn. The tumour soon afterwards nearly disappeared. Three weeks ago she was admitted into St. George's Hospital, suffering some discomfort and pain, and a tumour was found in the left hypochondrium of remarkable mobility in all directions. On opening the abdomen it was found to be behind the great omentum and to be connected with the pancreas at the splenic end. It was enucleated and found to contain a yellow fluid of sp. gr. 1024, solid with albumen on heating, turbid, and iridescent from presence of cholesterin.—Mr. CLUTTON said that the tumour shot out of the wound quite easily, dragging with it the tail of the pancreas. Mr. Hulke's case reminded him of a recent paper by Mr. Jordan Lloyd, in which reference was made to instances of inflammation of the lesser cavity of the peritoneum, a kind of cyst being formed, of which the pancreas constituted part of the wall. When he was enucleating the cyst the pancreas bled very freely, and he had to introduce a glass tube for

drainage. There was persistent vomiting afterwards, which was immediately relieved on the tube being shifted. At the present time there was a large quantity of clear discharge, which was evidently pancreatic fluid.—Mr. GOULD inquired if there was any history of injury. He had operated on two cases. In one a permanent fistula resulted, and malignant growth afterwards developed round this, which proved fatal. In the other case the cyst was fixed and could not be brought to the surface. With a finger in the cyst, he therefore cut down behind, below the twelfth rib, and drained it posteriorly; the fistula rapidly closed up.—Dr. NEWTON PITT mentioned a case which he had published with Mr. Jacobson in the Transactions of the Royal Medical and Chirurgical Society; since that time the cyst had refilled. He considered it best to drain posteriorly, especially if there were likely to be permanent fistula.—Mr. HULKE, in reply, said that the cyst was near the head of the pancreas in his case, and there was no trace of peritonitis. There was an instance recorded of a pancreas so movable that it formed part of an intussusception, and the same writer mentioned two cases of enucleation of cyst which proved rapidly fatal. In the instance he recorded the swelling began in childhood, but there was no history of injury. The urine was free from sugar.

Dr. ROPER and Mr. W. A. LANE gave details of a case of Excision of a Cancerous Stricture of the Small Intestine from a case of complete obstruction of seventeen days' duration. The patient, a lady aged fifty-four, had been under Dr. Roper's care for many years, suffering from habitual constipation, for the relief of which it was necessary to render her motions quite fluid. In March, 1891, she had an attack of obstruction which yielded to acute treatment by enemata and purgatives; and after this she had several attacks which were successfully treated in a similar manner. Dr. Roper observed that during the last year her abdomen had gradually increased in size, though she lost flesh steadily; also that the small intestines were obviously distended and hypertrophied, while at no time had he been able to find any distension of the large intestine, which was capable of holding a large fluid enema. He had never been able to find any hard mass in the abdomen. He came to the conclusion that the patient was suffering from a malignant stricture of the lower part of the small intestine, and had discussed with her the advisability of having something done; but to this she would not consent. On March 7th she was seized with obstruction, which did not yield to the treatment which had been successful on previous occasions. Although Dr. Roper urged on the patient and her friends the necessity of an operation, they would not consent till it became obvious that she could not survive many hours unless she were relieved. Mr. Lane then saw her, at Dr. Roper's request, on March 25th, seventeen days after the onset of the obstruction. They felt that, in the face of the frequent vomiting of fluid fecal material and of the very prostrated condition of the patient, an anæsthetic was inadmissible. A small opening was made in the middle line, when a tight annular growth was found just above the left sacro-iliac synchondrosis. As the mesentery was much shortened and puckered, it could not be pulled into the median incision. Another incision was made directly over it, and with the greatest difficulty it was drawn between the edges of the wound, where it was fixed by means of a steel rod covered with rubber transfixing its mesentery. A Keith's tube was tied into the bowel above the stricture, through which the intestinal contents escaped freely. The very enfeebled condition of the patient rendered any such operation as the removal of the growth and the establishment of intestinal continuity quite impossible. A few days afterwards the growth was excised and the proximal and distal portions of the gut were carefully united by sutures. Most of this suturing yielded, under the pressure exerted by the contents of the bowel, within a few days. When the patient had gained strength and flesh the question of establishing intestinal continuity and closing the abdominal wound was discussed with her, but she refused to consent to any operation which entailed any risk, being very comfortable as she was—in fact, more comfortable than she had been for many years, since she had regained her natural appetite and was no longer troubled with her bowels. The growth was situated in the ileum, a few inches above the ileo-cæcal valve. It only allowed of the passage of a director, and then with some difficulty. The points of interest in the case were the accuracy of the diagnosis, the fact that with such a minute channel through the growth the patient was able

to drag on a more or less miserable existence for a considerable time, the long history of partial obstruction extending over many years, the duration of the interval that elapsed between the onset of the final attack of complete obstruction and the operation, and the comparative rarity of malignant disease of this part of the intestine.—Mr. HULKE said that in cases in which it was impossible to administer an anæsthetic on account of fecal vomiting he had seen great benefit follow emptying the stomach with a syphon and washing it out with a weak solution of boric acid; after this the anæsthetic could be given without risk.—Mr. LANE said he had not found so much benefit follow this manoeuvre; fluid from the intestines rapidly reaccumulated in the stomach, and would flow freely away from an œsophageal tube left in during the operation.—Mr. SYMONDS referred to a case under the care of Dr. Goodhart on which he operated and found a tumour of the small intestine as large as two fists, which he then regarded as malignant. As the whole of the mesentery was thickened and infiltrated with growth he could not excise it, and therefore opened the small intestine above the tumour. Two years had since elapsed; there was a small fistula in the groin and the tumour had disappeared. The subsequent progress of the case showed that it could not have been malignant.—Dr. HADDEN, referring to the case related by Dr. Roper and Mr. Lane, remarked that it was very unusual for obstruction of so many years' standing to be due to a malignant growth.—Dr. ROPER, in reply, said that the vomiting was so severe that it prevented an anæsthetic being given. He thought the case related by Mr. Symonds was an instance of tubercle.

## PROVINCIAL MEDICAL SOCIETIES.

LEICESTER MEDICAL SOCIETY.—At the first meeting of the session the PRESIDENT (Mr. C. F. Bryan, M.R.C.S., L.R.C.P.) took as the subject of his address Arsenic as a Prophylactic. Arsenic, he said, when given internally has a tonic influence on the nervous system and stimulates the heart, as is observed in the arsenic eaters of Styria, who are able, after becoming accustomed to it, to consume large quantities, and they also teach their children to eat arsenic from an early age. This is done with the view of "improving their wind," and so enabling them to ascend the high mountains which abound there without any difficulty. These arsenic eaters assert that it prevents illness. It had been stated that those who are taking arsenic are unsusceptible to vaccination and to the incidence of small-pox. He also drew attention to the remarkable power of arsenic to arrest scarlet fever, and cited an instance in which more than twenty children of a workhouse school were struck down with disease. The president gave particulars of several cases of infectious disease from his private practice, in which he had administered this drug as a prophylactic, evidently with success. The cases included scarlet fever, diphtheria and influenza. He concluded—"I feel sure also that there is a grand field for observation of the use of arsenic in surgical cases, and I have no doubt in my own mind that if surgeons would only prepare their patients for a few days previously to a severe operation with small doses of arsenic the results would be even far better than they are now. I may add that, if given in the liquid state, I generally use something of this kind, which is pleasant to take and is liked by children: Liq. arsenicalis, twenty-four minims; syrup. aurantii, half an ounce; aqua to three ounces; two teaspoonfuls to be taken three times a day after meals, and after the first week twice a day. Now, gentlemen, I have pursued this treatment for the last ten years whenever it was practicable, and I most strongly recommend you to give it a fair trial, feeling sure that you will be able to substantiate what I have laid down—viz., that in arsenic we have—shall I say?—a perfect prophylactic in most infectious diseases."

MANCHESTER PATHOLOGICAL SOCIETY.—A meeting of this Society was held at Owens College on Wednesday, Nov. 9th, Dr. J. S. Bury, President, in the chair.—Mr. W. COATS showed a young woman aged twenty-three the subject of Melanotic Sarcomatous Growths.—Dr. NATHAN RAW exhibited specimens, with drawings, of a Lung the seat of Extensive Pulmonary Fibrosis, occurring in a syphilitic subject.—Mr. SOUTHAM showed a complete Cast of the Bladder, from a case of Exfoliating Cystitis, passed per urethram by a female. For some weeks previously she had suffered from a severe attack of cystitis, apparently due to the irritation

caused by wearing a pessary. After the expulsion of the cast or false membrane the symptoms gradually subsided and the patient made a complete recovery.—Dr. REYNOLDS exhibited a large Aneurysm involving the whole Thoracic Aorta, measuring nine inches long and six inches wide. It contained clot weighing 3lb. Death was due to rupture into the trachea.—The following card specimens were shown : Dr. ASHBY : Cultivations of Streptococci from Blood of a case of Malignant Endocarditis. Dr. HARRIS : (1) Lympho-sarcoma of Mediastinal Glands, infiltrating Lung ; (2) Extensive Endarteritis in a Syphilitic Subject ; (3) Aortic Atheroma producing Partial Obliteration of Innominate and Left Carotid Arteries ; (4) Old Hydatid Cysts of Liver. Dr. KELYNACK : (1) Chronic Perforative Appendicitis ; (2) Lympho-sarcomatous Tumours in Mesentery of Vermiform Appendix. Dr. LEA : Trachea and Bronchial Diphtheritic Casts. Dr. WILLIAMSON : Microscopic Sections of Nerves showing extensive Peripheral Neuritis from a case of Alcoholic Paralysis.—A meeting was held on Nov. 16th, Mr. F. W. Jordan, Vice-president, in the chair.—Dr. MILLIGAN made some observations upon the operation of Excision of the Auditory Ossicles in cases of Chronic Suppurative Middle-ear Disease. The operation was performed for two reasons : (1) To rid the middle ear of any existing focus of disease and to secure thorough drainage ; and (2) to improve the condition of the hearing power. The anatomy of the middle ear was briefly sketched. The *modus operandi* of the operation was then described. In order to illuminate the field of operation, which is always very small, the light may be taken from an electric forehead lamp or from a limelight apparatus. A case was shown in which the operation had been performed with marked relief to the patient. The patient, a girl aged seventeen, had suffered from a severe attack of measles at the age of seven. At that time the left ear began to discharge and had continued discharging for ten years. Attacks of severe earache were frequent. Tinnitus was constant and attacks of vertigo common. The hearing power upon examination measured only  $\frac{1}{10}$  of the normal, and whispered conversation was inaudible on the affected side. The membrana tympani was found perforated in the anterior portion of Shrapnell's membrane and also in the posterior segment of the membrana vibrans. Granulation tissue protruded through both perforations, and a spot of caries was demonstrated on the head of the malleus. For five months careful local treatment was adopted. The granulations were removed and local applications made to the diseased areas. The suppuration, although diminished, was by no means entirely checked. The patient was accordingly put under chloroform and the remnants of the membrane and the carious malleus removed. Suppuration was arrested almost immediately afterwards. The hearing power increased from  $\frac{1}{10}$  to  $\frac{1}{5}$  of the normal. Whispered conversation could be heard at five feet from the ear. All pain and tinnitus had ceased. In addition there was almost complete formation of a new membrane two months after the date of operation.—Mr. F. W. JORDAN described a case of Intestinal Concretion of peculiar character. An independent gentleman, stout, and leading a sedentary life, had a severe attack of peritonitis, localised in the vicinity of the hepatic flexure of the colon, in the spring of 1890. In the summer of 1891 he had an attack of herpes zoster, one of the patches of which ultimately formed a large carbuncle on the back. While this was in progress it was discovered on August 14th that his abdomen was greatly enlarged owing to the existence of a tumour. When sketched on the patient's abdomen it presented the appearance of a large tumour with a narrow part or neck. The right hypochondrium was dull on deep percussion, which was thought to be due to a deep-seated portion of the tumour. There was dulness all over the tumour, which was close to the abdominal parietes. It felt quite solid and moved with respiration ; its surface was smooth and in shape nearly globular, though not quite, for it was inclined to be square at the lower part. The acute symptoms soon passed away and by the beginning of September the tumour had become smaller. It took cold and had sciatica in a mild form. For this he visited Bath and while there, in the middle of October, was seized with acute abdominal pain which lasted some hours ; he had jaundice for a few days. He remained well, complaining for a time of the sciatica and occasionally of gastro-hepatic derangements and constipation. On March 29th of the present year he was ill with general malaise, disordered liver, scanty dark-coloured urine loaded with pink urates ; and with one of his evacuations he passed a large concretion. At the present time his liver is still enlarged,

but not to the same extent as before. The concretion weighed six drachms, it was one inch and three-quarters long by one inch and a quarter broad ; it was cylindrical in shape and irregular, as if it had been subject to pressure while in a soft state and pointed at one end ; the other end was blunt and evidently broken off from another piece and has a conchoidal fracture. On section the concretion was seen to be made up of a large gall stone, having a thin coating of brown substance (cholesterin stained brown). The structure was such as to make it evident that this gall stone had been in close proximity with another one, end to end, and that the two had become fused together by further deposition of biliary matter. With regard to the tumour, the general shape of it, the history of the case, the probabilities, the absence of jaundice, and the continual presence of bile in the stools pointed to a distended gall bladder.—Dr. MORITZ showed two patients, twin sisters, twenty years old, who were both affected with Papillomata of the Larynx. The parents, as well as the other six brothers and sisters of the patients, were healthy. The theory which had been advanced that papillomata of the larynx might be caused by the inhalation of amniotic fluid mixed with gonorrhoeal discharges during birth found in these cases no support, as the mother gives no history of fluor albus and the patients had no ophthalmia neonatorum. One of the patients began to suffer from hoarseness when two years old ; in her case the larynx was found almost filled up with papillomata, and, though the voice was not completely aphonic, she suffered from considerable dyspnoea. The papillomata sprang from the right vocal cord, the right ventricle and ventricular band. The other patient commenced to suffer from hoarseness when eighteen years old ; she was completely aphonic, and also in her case the right vocal cord was affected, presenting several papillomatous excrescences on its upper surface and along its free margin. Dr. Moritz showed the growths which he had removed by means of a forceps of his own design, for which he claimed several advantages, with the result that the patients now had fully recovered their voices, though in one of the patients, who had not been seen for two months, a small papilloma had recurred.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At the meeting on the 16th inst. (Mr. R. C. Chicken, President, in the chair) Dr. BELL TAYLOR read a paper entitled "Vivisection : Is it justifiable ?" He said that any advance which we might hope to make in the direction of civilisation, any step towards the amelioration of the evils of existing conditions, would be mainly by way of the recognition of rights, not only of men, but also of those poor relations whom we call animals. The exigencies of our nature compel us, no doubt, to kill certain animals for food, and also in self defence, but nothing could justify deliberate cold-blooded and prolonged torture of any of them.—Dr. WM. RANSOM pointed out that the successful treatment of disease depended on knowledge of function and structure. Physiology had been advanced by experiment on animals—e.g., our knowledge of the circulation, respiration and the functions of the nervous system. By the same means the pathology of nervous diseases, the rationale of cardiac murmurs, the nature of inflammation, of myxœdema and of many infective diseases had been elucidated. Improved pathological knowledge had been an indirect gain to treatment.—Mr. HATHERLY said that while not advocating the total suppression of vivisection, or agreeing with all Dr. Taylor had said, he still considered Pasteur's treatment for hydrophobia had been an utter failure.—Dr. WATSON said Dr. Taylor's facts and arguments were the same which were served up at every anti-vivisection discussion, wherever occurring. He corrected Dr. Taylor's allegation that there was nothing to prevent an investigator repeating experiments which had been performed before.—Dr. CATTLE said Professor Horsley's experiments on monkeys had succeeded in proving the relation of the thyroid to myxœdema and settled many moot points in the space of a few months.—Dr. RANSOM proposed, and Dr. CATTLE seconded, a vote of thanks to Dr. Taylor for bringing the subject before the Society.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—At the meeting held on Nov. 10th (Dr. T. Oliver, President, in the chair) Dr. ROBERTSON brought before the members a man in whom he had drained the Antrum of Highmore on each side, on account of old-standing disease ; also a patient on whom a similar operation had been performed with a good result on account of œzœna.—Mr. PAGE showed (1) A man successfully treated for Ununited Fracture of Femur by sawing off ends of bone and putting up without

suturing the bone; (2) a man treated for United Fracture of Humerus by silver wire suture; (3) a lad of fifteen whose Kidney had been Removed for Hydro-nephrosis; (4) a woman whose Kidney had been Removed for Pyo-nephrosis of two years' duration—nephrotomy was first performed, and as soon as the patient's health was somewhat improved the kidney was removed; (5) a woman with very large Umbilical Hernia on whom a "radical cure" had been performed; (6) a man with Malignant Disease of Stomach where gastro-enterostomy had been performed—the patient had improved considerably; (7) a patient from whose jaw a large Bony Tumour had been removed; (8) two patients on whom Helsted's operation for radical cure of large Inguinal Hernia had been done with very good results.—Dr. GEORGE MURRAY showed a woman with a complicated form of Spasmodic Torticollis; she had suffered from chorea on more than one occasion.—The PRESIDENT showed a man who nine years ago received a Compound Depressed Fracture of the Skull. Latterly he suffered from left-sided epileptiform fits, followed by unconsciousness and then mania. He had been treated with large doses of bromide of potassium and had had no return of his attacks for some time. The President also showed a boy aged fourteen, with general venous distension and oedema. He regarded it as due to a cardiac lesion, with enlargement of mediastinal glands.—Dr. HUME showed a patient whose kidney he had removed. The kidney was extensively disorganised and contained many calculi. Dr. Hume also showed a man who was admitted, suffering from advanced epithelioma of the tongue. Through a long incision on each side the lingual arteries were ligatured and the submaxillary and their accompanying lymphatic glands removed. The result obtained was highly satisfactory.—Mr. WILLIAMSON showed a boy who, two years ago, suffered from suppurative osteo-mycelitis of the tibia. An incision was then made from one epiphysis to the other, the bone sawn across and removed. The leg was now as strong and useful as the other.—Dr. D. DRUMMOND showed a woman aged fifty, suffering from pseudo-bulbar paralysis.—Dr. LIMONT showed a girl aged fourteen, suffering from extensive favus of the scalp of eight years' duration.

PLYMOUTH MEDICAL SOCIETY.—A fortnightly meeting was held on Nov. 9th in the Society's library, Mr. Leah (President) in the chair.—Dr. L. FOX exhibited his case of Myxœdema, the notes of which were published in THE LANCET. The woman now walks briskly, syllabic speech has given way to quick utterance and the peculiar facies and hands are little marked. She continues to take extract of thyroid gland once a fortnight.—Mr. A. C. RENDLE showed a specimen of Sarcoma (?) in the Lower End of the Femur of a man aged twenty-seven.—Mr. LUCY showed (1) a Kidney, the seat of "primary cancer" removed from a child aged two years; and (2) a kidney with well-marked cloacæ, leading through the thinned cortex into ragged tuberculous abscesses of the medulla, removed post mortem from a man aged thirty-seven.—Mr. THOMAS exhibited for Mr. Swain (1) a piece of encrusted gum-elastic catheter removed suprapubically from an old man; and (2) a cast of a case of Dislocation upwards and forwards either (most probably) of the scaphoid or the trapezium and trapezoid, a luxation hitherto not mentioned in surgical classics.—The annual meeting took place on Nov. 16th, Mr. Leah (Stonehouse), the retiring President, taking the chair. The following office-bearers were elected:—President: Thos. Leah, M.R.C.S., Stonehouse. Honorary Treasurer: J. Elliot Square, F.R.C.S. Honorary Librarian: C. E. Russel Rendle, M.R.C.S. Honorary Secretary: R. H. Lucy, F.R.C.S. Library Committee: The President, Honorary Treasurer, Librarian and Secretary *ex-officio*, and Messrs. Rendle and Woolcombe. New members: Messrs. J. H. S. May, G. F. Aldous and R. S. Thomas, Plymouth; R. B. Mole, Callington; and J. H. Gough, Horrbridge. It was decided to admit members residing beyond five miles from Plymouth on payment of the annual subscription only. Twenty-three members and the following guests—Fleet-Surgeon Ellis, R.N., Surgeon-Captain F. B. Mathias, A.M.S., and Mr. Elliott—subsequently dined together. The Society has acquired a library and a reading-room of its own in Athenæum Chambers, George-street, in which, during the winter, fortnightly meetings will be held, alternately "clinical" and for the reading of papers, with discussions.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—At the meeting on Nov. 10th Mr. Snell, the President, exhibited his new ophthalmoscope, after which a discussion took place on Anæsthetics. Dr. PORTER and Dr. CLEAVER read papers on the subject. Referring to the administration of

other, Dr. Porter deprecated giving this anæsthetic too rapidly, as likely to favour excitement and struggling. In using Clover's inhaler he always allowed from four to six minutes for the induction of complete anæsthesia. He dwelt particularly on the maintenance of perfect quiet in the room as the best safeguard against excitement. When once the stage of voluntary resistance was passed the sooner complete muscular relaxation was attained the better. Dr. Porter then went into the question of the relative mortality from chloroform and ether, quoting statistics, and submitted that the mortality from chloroform was increasing. The conclusions of the Hyderabad Commission, and the experiments of Drs. Gaskell and Shore, and of Dr. McWilliam, were specially referred to in connexion with the action of chloroform and ether. Finally, some reasons were given for thinking that circumstances might have contributed to render chloroform less safe in the aggregate than it was forty years ago. Dr. CLEAVER then read a paper on the Advantages of Chloroform as an Anæsthetic, in which he stated that after twenty-eight years' experience, during which he must have given chloroform many thousands of times, he had only come across one death. Dr. Cleaver never attended to anything outside the respiration and left the pulse entirely alone. Chloroform was potent for good if properly handled; more powerful for evil if misused. In the discussion which followed Mr. W. F. FAVELL strongly urged the necessity of systematic practical instruction in giving anæsthetics. Mr. GARRARD (Rotherham) had used anæsthetics largely for twenty years both in hospital and private practice. He thought that the Medical Council should demand evidence of efficiency in giving anæsthetics. Dr. SINCLAIR WHITE and Mr. FRANK HARRISON continued the discussion. Mr. COOMBE expressed a general preference for ether to chloroform. He attended to the state of the pupil as well as to the respiration during chloroform anæsthesia. Dr. Keeling and Mr. Snell joined in the discussion. Mr. CHICKEN, President of the Medico-Chirurgical Society of Nottingham, expressed the great pleasure and profit he had derived from the papers and the discussions. Personally, and in the absence of special conditions, he preferred to operate on a patient under chloroform rather than ether. There was less hæmorrhage and less vascular excitement, and the patient always seemed so much quieter. He asked the advocates of chloroform, before condemning ether, to be sure that their sample was thoroughly good. On the motion of Dr. ARTHUR HALL, which was seconded by Dr. MARTIN, the discussion was adjourned till next meeting.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—At the meeting held on Nov. 23rd (Dr. Pollok, President, being in the chair) Dr. MURDOCH CAMERON showed a Dermoid Ovarian Cyst, several small Fibroids and a Uterus with a mass of small fibroids in its walls, all removed from an unmarried woman, aged forty-eight years.—Dr. ROBERT JARDINE read notes of 1028 Confinement Cases, being the report of two years' work at a branch of the Glasgow Maternity Hospital; 932 were confined at full term, 65 prematurely and 31 aborted. There were 13 cases of twins. The operative cases were—forceps, 63; version, 10; craniotomy, 1; induction of premature labour, 1. Full notes were given of the 5 fatal cases. There were 7 cases of accidental hæmorrhage and 1 of marginal placenta prævia treated successfully. There were 6 cases of post-partum hæmorrhage and 2 of eclampsia. He induced premature labour at seven and a half months; in 1 case with a conjugate of 3" and in another of 2½" he did craniotomy. The placenta was adherent 16 times; syphilis he believed to be the most frequent cause.—The PRESIDENT said he never gave ergot to assist labour, but frequently used it just as the head was on the perineum. In severe hæmorrhage he never gave it, as he considered it had a very depressing action upon the muscular fibre and might extinguish the efforts of a flickering heart.—Dr. S. SLOAN congratulated Dr. Jardine on the low mortality, considering the nature of the work. He preferred aseptic to antiseptic midwifery.—Dr. M. CAMERON said it was rare to find the perineum tear from the anus. He believed the long, straight forceps was very apt to plough up the perineum. The best treatment in septic cases was proper and frequent douching of the uterus with perchloride. Abortions and hæmorrhages, he believed, were very frequently due to syphilis. He always interfered early in all cases of hæmorrhage.—Dr. RICHMOND said the small number of placenta prævia cases and craniotomies agreed with his experience of twenty-five years' work. He had only had some two or three cases of puerperal fever, and he took no elaborate precautions and used no antiseptics.—Dr. JARDINE, in replying, said that he was not aware of there having been any more than five deaths

## Reviews and Notices of Books.

*The Artificial Feeding and Food Disorders of Infants.* By W. B. CHEADLE, M.A., M.D., F.R.C.P. Second Edition, Revised and Enlarged. London: Smith, Elder and Co. 1892.

WE are glad to see a second edition of Dr. Cheadle's work. It fills a niche in medical literature, and fills it well. The present edition "has been revised throughout and some new matter added to the text, more particularly with regard to the sterilisation of milk, the relation of eruptions of the skin to diet and other points of practical interest." Dr. Cheadle sums up the essential conditions to be observed in the diet of infants as follows: (1) The food must contain the different elements in the proportions which obtain in human milk; (2) it must possess the anti-scorbutic element; (3) the total quantity in twenty-four hours must be such as to represent the nutritive value of from one to three pints of human milk, according to age; (4) it must not be purely vegetable, but must contain a large proportion of animal matter; (5) it must be in a form suited to the physiological condition of the digestive function in infancy; (6) it must be fresh and sound, free from all taint of sourness or decomposition. In view of the discrepancies existing between the standard analyses of human milk the author has thought it well to have the subject thoroughly investigated anew. Accordingly, Dr. Luff has made careful analyses of twelve different samples of human milk. "Every element has been estimated directly by the latest and most exact method. In no case has the amount of an ingredient been estimated by mere difference, as has been the general practice in previous analyses." The proportions found are as follows: Proteid, 2.35 per cent.; fat, 2.41; lactine, 6.39; lime, 0.019; phosphoric anhydride, 0.026; other constituents of ash, 0.295; water, 88.51. These proportions differ materially from those of Payen and Gorup-Besanez. Dr. Cheadle deals very fully with the difficulties encountered by the infant in the digestion of cow's milk, and gives various suggestions for overcoming them. He finds the various kinds of milk, as regards the easy digestibility of the curd, to rank as follows: (1) Peptonised milk, (2) cow's milk with barley water, (3) cow's milk with lime water, (4) cow's milk with bicarbonate of soda, (5) condensed milk, (6) boiled cow's milk undiluted, (7) fresh cow's milk undiluted. The various artificial foods are fully considered and their several advantages and defects carefully pointed out. He discards veal-tea altogether as a diet, has no high opinion of beef-tea, but recommends raw meat-juice strongly. The various diet-diseases of children are dealt with in detail. The style of the writing is good and the arrangement of the type conducive to easy reading. We feel sure this volume will prove of much practical value to all practitioners who are largely engaged in dealing with children's diseases.

*Chemical Lecture Experiments.* By G. S. NEWTH, F.I.C. London: Longmans, Green and Co. 1892.

THIS work is a useful *repertoire* of experiments for the lecture table, of which no account has been introduced upon the authority of a verbal or printed description; but each experiment has been the subject of the author's personal investigation, and the whole of the woodcuts used for illustration with the exception of three have been made from original drawings. The book contains no less than 632 experiments, all admirably described and of the kind which are calculated not only to excite the student's interest but to clearly point out to him the lessons which they are intended to convey. The scope of the work is limited to inorganic chemistry, but excellent

chapters are to be found at the end of the book on experiments on dissociation phenomena and the liquefaction of gases, followed by instructions on the use of the lantern for purposes of illustration. The appendix contains valuable data, like the absorption equivalents of various bodies for certain gases, the critical temperature of gases, the temperatures of dissociation and so on. Experiment No. 326 is as interesting as it is simple, and we quote it as a type of the rest. It is devised to show the influence of suspended matter upon the formation of fog. A large flask is exhausted of its air by means of the air pump and air is allowed to re-enter through a glass-tube containing a plug of cotton-wool. When the flask has thus been filled with air comparatively free from particles one or two strokes of the pump are made, and the cooling effect of the sudden expansion of the air within the flask will result in the deposition of moisture in the form of a fine rain. If now unfiltered air be allowed to replace that removed by the pump and the experiment be once more performed, a dense fog will immediately make its appearance, which will continue for some time. If a trace of coal-smoke or fumes from burning sulphur be substituted, it will be seen that the fog then produced will be much more permanent than the former. Mr. Newth's book undoubtedly fills a gap, for a really trustworthy record of experiments for lecture demonstration and other purposes has long been required. It will be especially valuable to the student of chemistry, whilst to the lecture assistant such a book is simply a *sine quâ non*.

*Roaring in Horses: its Pathology and Treatment.* By P. J. CADIOT. Translated from the French by T. W. DOLLAR. London: Swan Sonnenschein. 1892.

THE title of this little work does not harmonise with its contents, which only deal with the surgical treatment of unilateral paralysis of the horse's larynx. This somewhat common morbid condition in the equine species is generally confined to the left side of the larynx, and the "roaring" is due to the falling forward and downward of the arytenoid cartilage on that side, thus narrowing the aperture for admission of air into the tube during inspiration—hence the "roaring" heard when the horse is moving at a fast pace. The displacement of the cartilage depends upon atrophy of its special muscle—a dilator of the larynx—which is brought about by some interference with the left recurrent nerve, the origin and position of which expose it to damage in more ways than one.

To remedy the roaring, extirpation of the arytenoid cartilage has been successfully practised, and it is to the operation itself that Professor Cadiot chiefly devotes his attention. The French veterinarians are very expert and bold operators, their boldness being mainly due, it is to be presumed, to their being excellent anatomists; and the author describes in a very methodical manner the different stages in the *manuel opératoire*, illustrating them by well-designed figures and giving full directions for the after-treatment. It is very probable that in the course of time this mode of relieving distressed horses and thereby rendering them useful will become popular, though the operation needs much skill and dexterity. Nevertheless, under chloroform the horse remains perfectly tranquil; and as accidents arising from the employment of anaesthetics on horses are exceedingly rare, there is no reason why the operation should not be resorted to—in at least severe cases.

*Recueil de Mémoires, Notes et Observations sur l'Idiotie.* Par Dr. BOURNEVILLE. Paris: Aux bureaux du Progrès Médical. 1891.

THE high authority attaching to the name of Dr. Bourneville in connexion with the subject of idiocy points to him as one peculiarly qualified to carry out the idea which this volume

embodies. This idea is to present the various views which have been held by different men as regards the nature of idiocy and also as regards the educability of idiots, so that it is really of the form of an encyclopædia on the subject. It may be thought that a better method would have been to present shortly and succinctly the views of the different authors who are allowed to speak for themselves—sometimes at considerable length, it must be confessed—but those who are particularly interested in the subject will be glad to have in such a volume as this easy and convenient access to authoritative statements by those who are entitled to speak with the authority which experience and research bestow. The editor has written an interesting preface, and we doubt not the work will be interesting to many, but chiefly to alienists.

#### LIBRARY TABLE.

*Medical Microscopy: a Guide to the Use of the Microscope in Medical Practice.* By FRANK J. WETHERED, M.D. Lond. With Illustrations. Pp. 412. London: H. K. Lewis. 1892.—This work is a very complete manual, containing all that a student need learn of the various modes of preparing and mounting sections and of examining the fresh tissues and fluids of the body. Dr. Wethered has been for some time past a teacher in the medical school of the Middlesex Hospital, and has therefore experience of the wants of students and of the best method of supplying them with the information they require. The first chapter is devoted to the microscope, which he rightly counsels should be simple in construction and should be solid, and be supplied with good adjustments and an immovable stage. A brief account is given of Abbé's chromatic condenser and camera lucida, and of various microtomes. The next chapter is devoted to the processes of hardening and decalcifying and of embedding in paraffin and celluloidin. Then follows an account of the different methods of staining, and the reader who requires the newest and best methods will not be disappointed, for in successive paragraphs Dr. Wethered gives the hæmatoxylin and eosin, the carmine and picric acid, the lithium, carmine, alum, ammonium and borax carmine, safranin, Bismarck brown, or vesuvin and litmus methods and the plan of treble staining. The sixth chapter is devoted to selective stains, amongst which he gives silver nitrate, gold chloride, osmic acid and methylene blue, and, in addition, Löffler's, Kühne's, Gram's, Weigert's, Neelsen-Ziehl's and Gibbes' various methods. The processes for clearing and mounting are also given. The latter part of the work is devoted to the study under the microscope of the various animal tissues, organs and fluids, both normal and pathological, including therefore the blood, urine, feces, sputum and other discharges. The three final chapters are devoted to the consideration of the cutaneous parasites, of food and water, and of bacteriological methods. The illustrations are both numerous and good. It is a very good volume of an excellent series.

*Arrested Pulmonary Tuberculosis.* By JAMES KINGSTON FOWLER, M.A., M.D. Cantab., F.R.C.P. London: J. & A. Churchill. 1892.—Within small compass and with exemplary directness and force Dr. Kingston Fowler adduces irrefragible arguments for the view that a large number of cases of tubercle of the lung undergo spontaneous arrest, and that in consequence to speak of phthisis and its stages leads only to confusion and error. He would discard the term "phthisis" altogether, and would group the cases of tubercle of the lung under the four heads of (1) pulmonary tuberculosis, which includes all the ordinary cases commonly spoken of as "chronic phthisis"; (2) miliary tuberculosis; (3) caseous tuberculosis; and (4) fibroid tuberculosis. There is much to be said in favour of this classification, which harmonises better with modern conceptions of the etiology and progress

of phthisis, than the older and more vague nomenclature. But knowing the tenacity with which medical terms are held—even long after they have become obsolete—we fear it will be futile to look for a thorough change in this particular. Dr. Fowler next proceeds to analyse cases in which after death "obsolete lesions" evidently of tuberculous origin were met with. He has collected them from the post-mortem records of the Middlesex Hospital, and a large proportion of the examinations were made by himself. These cases are arranged in four series as follows:—

1. Cases in which death was due to a non-tuberculous disease ..	177
2. Cases in which death was due to acute tuberculosis .. .. .	19
3. Cases in which death was due to pulmonary (non-tuberculous) disease .. .. .	6
4. Cases headed "phthisis" or "chronic phthisis" in the reports which showed clear evidence of a period of arrest .. .. .	17

The frequency of arrest is then deduced, and the processes whereby it is attained are described as (a) encapsulation by the formation of an inflammatory zone; (b) elimination, leaving a cavity with thickened walls, and (c) fibroid conversion of tubercle. The general inferences to be gathered from this admirable study are that tuberculous disease of the lungs is extremely common, that it is often arrested and plays no part in the after history of the case, and that the measures to encourage this beneficial change are those which improve the general health, or, in other words, fortify the powers of resistance to disease.

*Influenza; its Pathology, Symptoms, Complications &c.* By JULIUS ALTHAUS, M.D., M.R.C.P. Second Edition. London: Longmans and Co. 1892.—We owe the author of this really valuable contribution to medical literature an apology for so long delaying to notice his work, which is an extension of the *brochure* he published early in the year. Dr. Althaus seems convinced that influenza is a bacillary disease, and refers its phenomena in the main to the action of the toxine upon the nervous system. He is also a pronounced "contagionist." He has collated a large and interesting series of clinical facts which have been recorded in the recent pandemic; and doubtless when a third edition of the book is called for Dr. Althaus will be able to add still more to this part of his subject, and to embody in the work a notice of the collective investigations carried on by the Berlin Medical Society. The style in which the book is penned is clear and vigorous, and we have no doubt that it will occupy a foremost place amongst the monographs evoked by the recent visitation.

*Archives des Sciences Biologiques.* Publiées par l'Institut Impérial de Médecine Expérimentale à St. Pétersbourg. Tome I., No. 3. 1892.—This number of the Archives contains an article by Dr. Blachstein, entitled "Contribution à la Biologie du Bacille Typhique." Working with recent cultures of bacteria isolated from organs of patients who had died from typhoid fever at the height of the disease, and with organisms taken from the fresh typhoid stools he has tried to determine whether the typhoid bacillus has any normal *habitat* outside patients affected with the disease and to find a good method for the bacteriological examination of drinking water. As a result of his investigations he maintains that neither the one nor the other presents insurmountable difficulties, but he finds (1) that the production of large or small quantities of carbonic acid in the typhoid fermentation has no importance as far as a diagnosis of the typhoid bacillus grown upon solutions of glucose is concerned; (2) that the formation of levi-rotary paralactic acid is a very important characteristic, especially in the case of those typhoid bacilli which have the faculty of determining energetic fermentation—these, of course, are the most important; (3) that typhoid bacteria isolated from a dead body are attenuated; (4) that as yet we have no satisfactory evidence as to the phylogenetic relationship between typhoid bacilli and those bacteria normally found in the intestine.

# THE LANCET.

LONDON: SATURDAY, DECEMBER 3, 1892.

THE Medical Council is at least entitled to the credit of a short meeting. Notwithstanding the number of delicate and difficult questions it had to deal with, it sat only four days—that is, from Tuesday to Friday inclusive. This was partly due no doubt to the fact that many of these questions were postponed rather than settled, but even so there was a spirit of despatch in the Council which is to be commended. It is certainly true that short meetings are not always for the good of the public or the profession. But, on the whole, it must be allowed that, with several questions on the programme of the late meeting, the best thing to do, for one reason or another, was to postpone them. This was the case with reference to the reports of the Visitors and Inspectors of certain examinations. Dr. HAUGHTON, for example, was eager to be at the assailants of the Final Examinations in Dublin University. But the Council had not seen the answer of the body criticised, and neither on the report nor on the reply to it had the Examination Committee had time to comment. It is obviously desirable that these reports should be discussed while they are fresh in the memory of the visitors, and there is an advantage in taking them in groups rather than altogether. Accordingly a motion was passed which will require the Council to deal at their meeting in May with all the reports that are received by the end of March. So with the important question of the propriety of the licensing bodies dealing *primarily* with cases of misdemeanour or unprofessional conduct in their members before the matter came under the notice of the Council. This is an abstract question. But it did not arise in that form before the Council. It arose in connexion with an actual case now before the law courts. It was obviously proper to leave the abstract question over till the case of appeal has been settled. Another matter under discussion was the action of the Medical Council in respect of continuing its recognition of the preliminary examination of the Apothecaries' Society. The Education Committee was prepared to put pressure on the Apothecaries' Company to leave to other bodies the examination in preliminary subjects which it now holds, and in which it examines about 800 candidates a year, only a small proportion of whom take its licence. But the Medical Council as a whole, has always dealt tenderly with the Society of Apothecaries. Influential members, such as Sir JOHN SIMON and Sir RICHARD QUAIN, have saved it from the fate which outrageous fortune might have brought on it if it had been left to the tender mercies of other medical authorities in London. The Council, therefore, resolved still to temporise in recognising the examination, which serves as a portal to the profession, not only to those who take the licence of the Apothecaries' Society, but also to large numbers of those who proceed to the examinations of the English Conjoint Board, which is obviously unsatisfactory. When there is such a universal conviction that the best thing for the profession and

the public is to hold high the standard of the preliminary examinations, it cannot be defended that the Apothecaries' Society should hold this great key. Even if its examination is not so lax as the high proportion of "passes" and the general run on the examination suggest, it is not reasonable to ask that other bodies should accept its standard. The real culprits who are guilty of letting into the profession, those whose general education is grossly defective have yet to be detected. And there is evidence enough that other bodies, of whom more might be expected, are not without blame, but it is clearly desirable as a preliminary measure that the work should be thrown on bodies which have public sanction and responsibility in educational questions.

Sir WALTER FOSTER'S proposal that the Council should support the demand for an increase in the direct representation of England and Wales was rejected. It is to be regretted that this proposal, after a few short speeches on the subject, was shelved by the previous question. Whatever the objections of the majority of the Council to this step—some of which are not unreasonable, especially the argument that it would add to a Council already too large—it is one for which much has to be said, and was indeed well said by Sir WALTER FOSTER. It is scarcely courteous to extinguish such a debate by the use of the standing order which allows no further debate, and not even the reply of the mover of the resolution. Any animus against direct representation should not be shown, however much it may be felt.

The action of the Council in penal cases will be differently judged. There can be no doubt that the narrow but severe single weapon in the hands of the Council—that of erasure—and the uncertain and in some cases irrevocable action of the medical authorities exercised subsequently to that of the Council make the use of it extremely responsible. This is a point which the critics of the Council do not always take into consideration in charging the Council with undue levity. The whole subject will need further attention if the licensing authorities and the Medical Council are to act harmoniously and effectively. The intimation that the doctrine of "covering" will be applied to dentists who carry on business through the means of unqualified assistants will, it is to be hoped, have a salutary effect. The discussion on Dr. RENTOUL'S memorial on the subject of the certification of midwives by unauthorised societies will serve to elucidate a difficult and complicated subject. On the whole, the meeting was one of interest, and brings the Council more than ever face to face with the body and life of the profession from which it derives its existence and its importance.

A REPORT compiled by Dr. ASTLEY GRESSWELL, health officer of the Colony of Victoria, on small-pox introduced into Australia by the Royal Mail ss. *Oroya*, has especial interest at the present moment, for it indicates in a forcible manner just that which may be expected from reliance on a system of quarantine against small-pox even in the case of a country which is free from the infection and remote from other countries where the disease exists; it also sets out the compulsory measures which it is necessary to resort to where the quarantine system fails; and it shows how hopeless it is to attempt to deal with small-pox without recourse to vaccination.

The malady was first detected in the case of a man twenty-eight years of age, who was found to be ill in the Victoria Coffee Palace in Melbourne, and by the time he was ascertained to have small-pox the passengers were already scattered about in Victoria and neighbouring Australasian colonies. Great precautions are taken against the introduction of small-pox into Australia, a rigid quarantine is maintained against it, and Dr. GRESSWELL tells us that prior to the arrival of the *Oroya* there had been no case on the continent for several years.

The quarantine system failed in this instance under the very circumstances in which it may always be expected to fail—namely, by reason of an unrecognised case of small-pox in a person who, approaching adult life, had been once vaccinated in infancy. The patient was taken ill about fourteen days after leaving England; others having associated with her on board contracted the disease, and it was one of these latter who was detected with small-pox in Melbourne. Thus it happens that "in this instance the mechanism for preventing introduction of small-pox into Australia altogether failed." Instant measures had then to be taken to supplement the system that had failed, and the story is interesting in its details. Four constables were rapidly procured, two were placed in front and two in the rear of the coffee palace, and no egress was allowed except on the condition of submission to vaccination, which was carried on until midnight, when about sixty persons had undergone the operation. The police cordon was, however, maintained. The next morning the process was continued, and it was only on its completion that the cordon was removed. But by this time the whereabouts of the first patient had been discovered, only, however, after people living elsewhere had been in more or less direct contact with her. Strict instructions were once more issued "that no one, under any circumstances, was to leave the house." The police station was again requisitioned for a series of cordons round the implicated or suspected houses, and with the aid thus procured vaccination, with measures of disinfection, was once more resorted to; but even this did not check the mischief that had been already wrought by the one unrecognised attack of small-pox. As late as June 24th another person sickened, another police cordon was arranged, and much the same process was gone through, the actual patients being in each case removed to the quarantine hospital as soon as was practicable. The disease also extended to other colonies—notably to New South Wales, where four persons arriving by the *Oroya* and three of the residents were attacked.

We are thus provided with an example of that which may be anticipated wherever, under the plea of the liberty of the subject, no law as to compulsory vaccination is tolerated, or wherever any such existing law is repealed. We are told by a correspondent, Dr. CHARLES BAGB, of Kington, Victoria, that compulsory vaccination has been the law of the land in Victoria for nearly forty years; but notwithstanding this he states that "quarantine is much relied on," and he cites an instance to show that inhabitants flee from houses where small-pox appears from "fear of quarantine." We hardly understand the relation in which the one form of compulsion stands to the other; we are only desirous of applying the lesson to ourselves; and so far as the police measures under which vaccination is enforced are concerned, we are forcibly

reminded of the evidence given before the Royal Commission on Vaccination as to the state of affairs which goes on in the United States of America, to the laws of which so many of our own people look as their beau ideal of personal liberty. So long as there is no small-pox to be feared the inhabitants may do much as they like; the moment a dread of the disease appears vaccination is enforced under pleas and by measures which would never be tolerated in England. It becomes simply a case of "There is no compulsion, but you must." In the one country one method of enforcement is adopted, in the other the compulsion is carried out under the authority of the police. Thus, under the influence of panic and by resort to exceptional methods, an attempt is made to imitate the system of compulsory revaccination which in Germany is carried out in a rational and statesmanlike manner.

In a small way illegal measures of control have, under somewhat similar circumstances, already been resorted to in this country in places where vaccination is neglected; and it is this sort of thing in an intensified form that we shall have to look forward to if our Legislature should ever give heed to the demands of those who are fascinated by the contentions of people who talk loudly of the success of their quarantine when an odd family has to be dealt with, but who maintain a significant silence as to its failure when circumstances occur which in some slight way put the system to the test.

No one can fail to admire Dr. GRESSWELL'S activity and determination in the face of the danger he had to meet. We certainly shall not stop to ask how far the interferences with liberty to which the people were subjected were legal or the reverse; but we would carefully remember his warnings. The circumstances were favourable to the success of the measures which were resorted to; but he tells us that had exceptional promptitude not been practicable, the consequences would almost certainly have been that small-pox would have "extended rapidly," and so "the question of the endemicity of the disease in Victoria, and by reason in Australia, would again have become prominent." In fact, he admits that a similar success is not likely to be repeated; hence he urges his one prominent lesson, that the prevention of small-pox can be brought about "simply and solely by vaccination and revaccination." The experience in connexion with the *Oroya* comes to his aid in enforcing this vital part of his story. No person who had been successfully revaccinated contracted small-pox, notwithstanding exposure to infection. Of the children on board the vessel only one—a girl of five years old—had small-pox, and she "had not been vaccinated." Here we have one more proof of the value of a recent successful vaccination. Infancy and childhood are protected by the primary operation performed in the first few months of life, and adults are protected by submitting to a repetition of the protective process.

We deal elsewhere with Professor FRASER'S remarks on the propriety of separating the study of the subject of materia medica proper from that of therapeutics, and on the respective place in the medical curriculum which these subjects should hold. Our present concern is rather with the question raised in the earlier half of the introductory address with which he favoured his class and which we published last week. This constitutes a veritable novelty, for which,

in the first instance, the Scottish Universities' Commission must be held responsible, but which seems to have the entire approval of Professor FRASER himself. The novelty has reference to the recognition by the Universities of Scotland of the tendency to specialism in the medical profession, and of the demand for it by the public, by the institution of a system for conferring degrees, or rather diplomas, in certain special branches of practice, a system foreshadowed in the ordinances in the following words: "Subject to regulations to be made from time to time by the University Court, the University may also confer diplomas in special branches of medical and surgical practice on graduates of the University in medicine and surgery." Hitherto when a student has shown special knowledge in the course of his University career, his University has recognised his merit by giving him a medal or other mark of distinction, and, later on, in the broad competition of life he has generally developed the special powers that were in him and justified the judgment of his teachers. Now the Universities propose to punish merit and to profit by it rather than to reward it; to subject their distinguished students at the end of the curriculum, and "*after the elementary training for the lower degrees*" (the italics are ours) "has been completed," to fresh studies lasting a year longer than the recently prescribed five years, and to one or more special examinations.

We regret that we cannot agree with the argument by which, as our readers will see, Professor FRASER justifies this new venture in University action. He himself says that to institute a "degree" for each special branch would be objectionable, because it would multiply degrees to an extent that would be detrimental to all degrees. But surely it is as objectionable to multiply diplomas as it is to multiply degrees, and for the same reason. The increase of specialism is rather an evil to be repressed than an advantage to be encouraged and fostered by Universities. It is not quite justifiable to say that the merits of specialism have been so admitted by the profession that the time has come for the Universities to stamp it with a series of special hall-marks. The profession has the greatest possible doubt about the advantages of any specialism save that which is the outcome of a man's own life and practice, and as such is recognised by his peers and his fellow-practitioners. A man who develops a gift for dealing with abdominal tumours or calculi of the bladder or kidney, or for treating diseases of the eye, must be reckoned with, and will always have accorded to him by his professional brethren the respect which he deserves, and of which they are the best if not the only judges. It is one thing to give a degree in one or other of the great branches of medicine and quite another to profess to send out raw young graduates ticketed with a label conveying a fictitious idea of their familiarity with highly technical branches of the medical art. Where is such a system to stop? Professor FRASER indicates that the medical faculty of his University has already expressed itself in favour of the creation of five special diplomas, respectively in ophthalmology, mental disease, laryngology with aural and nasal surgery, medical jurisprudence, and midwifery and gynaecology. This is a suggestive extension of the diploma-making business. If the ear and the nose are to be the subject of special diplomas, why not the liver,

the heart, the stomach, the rectum, and "the big toe"? It is certain that these organs or parts have as many claims to special attention and that most of them play as important a part in the economy of the body as those which have been selected for diploma-making by the Faculty of the University of Edinburgh. The terms "hepatologist," "cardiologist" and "renalist" might take a few months to be "understood of the people," but in the meantime the very strangeness of the titles would have its effect, and then the public would begin to think that there was something in it, and that these gentlemen with the new names ought to be consulted. Seriously we consider this to be a very questionable step on the part of the great University of Edinburgh. It would have done infinitely better service to itself and other Universities if it had resolved on strengthening the reputation of its present degrees and accentuating the difference between a degree and a diploma. Professor FRASER actually fastens by implication a kind of reproach on present degrees in comparison with these new inventions. They are to be the "lower degrees" for which only "elementary training is required"; the honours are to attach to the new diplomas! We venture to think that graduates of Edinburgh will not feel grateful to Professor FRASER for thus belittling the degrees which, as Select Committees and Royal Commissions have been assured, implied a higher training than that for ordinary qualifications. Universities can no longer stand on fine distinctions between degrees and diplomas, or on the multiplication of letters they can contrive to append to a graduate's name. If their *raison d'être* is to be maintained it must be by the higher standard required for their degrees, not by the creation of a distinction between "lower degrees" and superior (!) new-fangled titles, which will mislead the public and offend the profession. The proposals for new diplomas are as unfair to the graduates as they are unworthy of the University. The number of examinations is even now a serious evil; and it is proposed to add another torture to those already existing, and to turn out young men with "special qualifications for the practice of some selected branch of medicine or surgery," of which in the nature of things they have had a minimum of experience. The Scottish Universities have already as many students as they can cater for. Among them there are many men of whom they are specially proud and confident. Let them impose not a new examination on them, but some new reward. Above all let them look to the standard of their degrees in medicine and surgery that they be not "lower degrees," but true academic honours as distinguished from ordinary qualifications. If degrees are not this they are not what they pretend to be. And this leads us to the remark that the matter has a significant bearing on the grievance under which London medical students suffer. They are not able to obtain on reasonable conditions in London an M.D. degree, whilst Scottish universities propose to add to that coveted qualification the further attraction of a system of special diplomas. We commend the subject to the notice of the Royal Commission on the proposed Gresham University.

---

NORTH-EASTERN HOSPITAL FOR CHILDREN,  
Hackney-road, N.E.—The Lord Mayor will preside at the Festival Dinner to be held at the Holborn Restaurant on May 9th next in aid of the funds of this hospital.

## Annotations.

"No quid nmls."

### THE PREVALENCE OF SMALL-POX.

SMALL-POX continues somewhat slowly to extend the area of its distribution. In Warrington, where the fresh attacks numbered 76 in the week ending Nov. 12th, the new cases were only 32 in the week ending Nov. 19th, and a further decline seems to be taking place. The inhabitants are hurriedly seeking revaccination, at a rate and on a scale that can hardly be kept pace with. Lancashire has several centres of infection, Manchester, Liverpool, St. Helens, Wigan, Salford, Oldham and Chadderton being amongst them. At Salford preparations are in contemplation to meet a possible extension of the disease into the borough. Leeds remains seriously affected. The existing hospital accommodation is occupied, and cases are under treatment in their own homes. Other Yorkshire towns, such as Halifax, Rotherham, Barnsley and Bradford, have also had fresh cases reported. In London a batch of ten cases has occurred in Islington, and one case was reported from Hackney. In Leicester a distinct abatement has taken place; only two cases were reported in the week ending Nov. 19th. Other fresh outbreaks or isolated attacks of the disease are heard of from Castle Bytham, near Bourne, and Dronfield.

### THE FEEDING OF SCHOOL CHILDREN.

THERE can be no question that a child which from want of food is on the verge of starvation has neither mental appetite nor digestive power sufficient to deal with the material so freely and fully afforded by our national system of education. It is equally certain that many poor children who are now compelled to attend school are found to be, through no fault of theirs, in this destitute condition. We are thus brought face to face with an important social problem. Who is to feed these children? Social democrats at once answer the State, while others with as little hesitation throw back the burden of responsibility upon the defaulting or impoverished parents. We can hardly go wrong if we seek the true solution in a middle course. It would certainly be much more foolish than humane to indulge, and even to encourage, the culpable neglect of a careless parent by introducing any loose and general measure for allowing free meals at the cost of more active and provident members of the community, rich or poor. At the same time no one can stand by while children are being virtually crushed between the nether millstone of parental neglect and the pressure of grinding poverty. Compulsion if applied must not, it is clear, be limited to education. Working through parochial authorities it must wherever needful be made to energise the limp inaction of any who thus heedlessly desert their offspring, and it does operate in this way. In cases of excusable indigence the same power becomes a source of supply under our present system of parish relief, which, nevertheless, can hardly be expected to work without hindrance or omission, and thus it happens that a certain proportion of young school children are found to be simply starving under the eyes of their instructors. The school then becomes part of a machinery available for the detection of such want as lies within the province of parochial inquiry and amendment. Yet the actual work of amendment is to it no proper object of concern, and we fail to see how School Boards can be expected to undertake the duty of catering for bodily as well as mental sustenance. Any effort of this kind associated with the work of teaching should naturally therefore be accomplished by external agency—by the parish officials preferably—acting either upon or for the

parent, or failing these, by voluntary charitable organisations. We may take it as a circumstance creditable on the whole to our character for self-help that many of the latter bodies introduced by the "penny dinner" movement of 1885, and now united by a central committee, have been and are doing excellent work in the interest of poor children. Conducted upon a principle which requires wherever possible a trifling payment, but still admits the justice of providing for every necessitous case, we do not think that the system thus organised could be improved upon by any more general and probably less discriminating application of State relief. Its past efficiency in the cause of the indigent, its concern for these alone, and the obvious need of such provision as it affords are its unfailing guarantees of character and its titles to continued success.

### MUSIC AS A REMEDY.

THE connexion between music and medicine was discussed by Dr. J. G. Blackman at a recent meeting of the Portsmouth Literary and Scientific Society. The subject is one of interest both from a social and professional standpoint. In this instance it was regarded by the lecturer mainly in its medical aspect and was treated on similar lines to those with which readers of THE LANCET are familiar. The physiological foundation of musical therapeutics was examined and described as consisting in the power exercised by harmony over the vaso-motor function. Most will acquiesce in this view, which is also corroborated by the experiments of Riegel on the blood pressure and heart action during the performance of music. It follows naturally that the ailments most likely to be benefited by this means are those in which nervous disorder plays a leading part. A number of cases illustrating this point were quoted at the meeting referred to, and we should probably include among these one in which reduction of temperature followed the administration of "a dose" of melody. The violin takes high rank as a vehicle of the soothing property, and the other instruments best adapted to the treatment of disease by musical sounds were, in the lecturer's opinion, the harp and the pianette (not the piano), with which a few well-chosen voices might be advantageously combined. Dr. Blackman does not consider it feasible as yet to apply the musical method as above described in private practice, though he looks forward to its employment in hospital work, a hall being established in London where the services of musicians trained for this particular branch of their art might be obtained. While willing to admit the salutary effect of good music in many cases of nervous disease, we confess that an arrangement so elaborate does not seem to us to be called for by the exigencies of illness or justified by the importance of its probable effect. In any case of serious mental or bodily disorder the mild suasion of sweet airs must hold an altogether secondary place in the plan of treatment, and such as could usually be well filled with far less elaborate preparation.

### COUNTY SANITARY ADMINISTRATION.

THE Bucks County Council had under consideration last week the question of the appointment of a sanitary committee. The subject was brought before the Council by Mr. W. F. Verney, who cited the excellent work done by some other County Councils, particularly Worcestershire, where Captain Sir Douglas Galton was chairman of the Sanitary Committee and Mr. Fosbroke medical officer of health. He also read a letter from Miss Florence Nightingale, who had written: "We hail the County Council as being or becoming one of the strongest engines in our favour, at once fathering and obeying the great impulse for national health against national and local disease." Mr. Verney was warmly supported by Mr. S. Osborn, F.R.C.S., who, speaking as a medical man, dwelt on the valuable work such a committee would be able

to do. He stated that in his own locality he had several times tested the water-supply of the poor people's cottages, and found it nothing better than diluted sewage. He combated the argument that such a committee would not have sufficient work, and said that if they did their duty thoroughly and efficiently they would find ample employment to justify their existence. One or two members of the Council objected, the argument being used that it would create friction with the sanitary authorities within the county. Eventually the debate was adjourned until the next meeting. We trust that this motion will be adopted. If a committee were appointed to consider the circumstances affecting the health of the several communities in the county, it would find ample material with which to deal, and certainly no fear of creating friction with the authorities ought to deter the Council from calling attention to any circumstance requiring the intervention of the proper authority. The effect of a committee in stimulating a more efficient sanitary administration would at once become obvious if it were made acquainted with the success attending the efforts of County Councils like those of the West Riding of Yorkshire, Staffordshire and Worcestershire. The Council might well remember that every sanitary authority contains some members who would be in sympathy with its proceedings, and they would be able to give a great impetus to any attempts made to secure improvement in the sanitary condition of the county.

#### DEATH AFTER VACCINATION.

ON Nov. 26th an adjourned inquest was held at the Town Hall, Chelsea, touching the death of a child aged one year and ten months, who had died after vaccination had been performed, about three weeks previously. The lymph employed was obtained from the calf, and another child was vaccinated with the contents of the same tube. The latter infant did perfectly well, so it is only fair to assume that the unfortunate issue in the case of the deceased was due either to purely personal conditions of health, or to some extraneous cause other than vaccine lymph. Dr. Luff watched the case for the Vaccination Commission. Mr. Corrie Grant, barrister, represented the friends of the deceased. It appears that vaccination had been postponed more than once on account of the weakness of the child. The clinical history of the fatal illness is briefly as follows: During the first week nothing unusual happened, for at the end of that period the medical man who vaccinated the child examined the arm and signed the case as "successful." Some days afterwards the wound inflamed and the two vaccination areas became confluent. Eventually convulsions supervened and the child became jaundiced and died from coma. Mr. Pepper, who made the post-mortem examination, deposed that the body was well nourished. The tissues were deeply jaundiced. Externally there were no signs of injury or disease except the jaundice aforesaid and an ulcer on the left arm. The latter was deeply excavated, was one inch and three-quarters by one inch in diameter and showed that the vaccination sores had run together. There were no granulations in the floor of the ulcer. The axillary lymphatic glands were much enlarged and congested, but suppuration had not taken place. The joints were healthy. Internally the organs were healthy except for recent acute changes, evidently due to absorption from the ulcer. The kidneys showed cloudy swelling. The spleen was greatly enlarged and softer than natural. There was hypostatic congestion of the bases of both lungs with commencing consolidation. The brain, heart, stomach and intestines were healthy to all appearance. No signs of tuberculosis presented themselves. Mr. Pepper gave it as his opinion that death was due to exhaustion from tissue change consequent on septic absorption from the ulcer on the arm. He considered the vaccination was not directly the cause, but that indirectly it

was a factor, since it was the method by which the sore was produced in the first instance, and, moreover, the temporary disturbance of health due to vaccinia would somewhat enfeeble temporarily the child's strength. He came to the conclusion, however, that had the vaccination sores been kept clean and free from implantation of septic virus from without the issue of the vaccination would have been normal. Cross-examined by Mr. Corrie Grant, he said that from his observation it was not difficult to obtain calf's lymph free from blood, and that even if there was a slight admixture of blood and lymph it would not necessarily render the latter unfit for vaccination purposes. It was not the mere presence of blood that was harmful, but blood in a state of decomposition or infection with pathogenic germs. It was elicited during the inquiry that nothing but dry linen had been applied to the ulcer on the arm and that one of the child's attendants was suffering from ulcerated cancer of the breast. The jury found that the death was due to blood poisoning following vaccination, but how the blood poisoning was caused was not proved. They added a rider to the verdict blaming the mother and grandmother of the child for not paying more attention to the sore on the arm and for not calling in a medical man when the health of the deceased showed signs of failing. In our opinion the death was, so to speak, an accident, and we think that if strict antiseptic principles had been practised it might have been avoided. The negligence of the relatives of the child was clearly due to ignorance and not to wilful negligence.

#### TREATMENT OF OPHTHALMIA AMONGST THE CHILDREN OF THE POOR.

WE have had on several occasions to comment on outbreaks of ophthalmia at various metropolitan schools. The serious results of admitting even a single child suffering from ophthalmia to free intercourse with healthy children was shown in the case of the *Goliath* training ship at Grays, and when many are affected it is very difficult to know what to do with them. It is impossible to confine them for many weeks consecutively to the infirmary, and yet the managers of the school naturally hesitate to incur the expense of a special medical attendant and a staff of nurses, and the still greater expense of building sheds or other accommodation for what appears to them to be a comparatively trifling ailment and one likely to prove only temporary. It is only by slow degrees that the conviction is forced upon them that such a course is necessary, and by that time a very considerable number of the children have become affected. A large building is then at last constructed, a medical officer and nurses are appointed, and when treatment has been continued for a year or more the disease is practically abolished. Then comes the question—What is to be done with the building when there are no patients to occupy it? The medical officer and the nurses can indeed be dismissed, but the building must be kept up in some fashion. This difficulty has presented itself to the managers of the Central London School District, and we think that they have returned a sensible answer to the proposal of the Local Government Board that the vacant accommodation at the ophthalmic school should be made available for the reception of children from other unions and parishes upon terms which would enable the managers to ensure adequate accommodation for cases within their own district if increased need should arise. The report contains the following recommendations: "It is evident that in appropriating a building designed for 400 children to a total population of 111 only (and which it is to be hoped will be a steadily diminishing number) there must be a serious loss of space accommodation, to say nothing of the expensive staff necessarily kept up even for the reduced numbers; but having regard to the difficulty already experienced of exercising a complete supervision over the ophthalmic department, and to

the probability that the amount to be reasonably charged to other unions for children sent by them would not afford any sufficient recoupment towards the very large expense of keeping the same up as a permanent isolation school, we feel unable to recommend the managers to acquiesce in any such arrangement. At the same time it is much to be regretted that a building which seems well adapted for the treatment of ophthalmia cannot be made available to relieve other unions and parishes of their ophthalmic cases; and seeing that there is every facility for making the isolation school establishment distinct altogether from the Central London District School with separate approaches, we recommend that the Local Government Board be informed that, whilst not seeing their way to adopting the suggestions of receiving children suffering from ophthalmia from other establishments, the managers would be prepared to entertain a proposal for disposing on equitable terms of the ophthalmic building, with a sufficient portion of land for the purposes of an institution for ophthalmic cases under separate management and authority, to which institution the guardians of the unions now comprising the Central London School District might send their children suffering from ophthalmia in common with children so suffering from other unions and parishes in the metropolis."

#### NOTIFICATION PROCEEDINGS AT BRADFORD.

THE editor of the *Bradford Daily Telegraph* publishes the following announcement in his issue of Nov. 23rd:—"I have been requested on behalf of the Sanitary Committee to warn the local doctors of the possible consequences which may follow from a neglect of the duty which the law lays upon them. The authorities will not permit the regulations to be treated as a dead letter, and are determined to prosecute the first doctor to whom they can bring home a charge. In the meantime, in the view of the great increase in scarlet fever, their inspectors have received instructions to make inquiries in all parts of the borough with the object of bringing to light cases independently of the medical reports, and collecting evidence for possible prosecutions." We sincerely trust that the editor is labouring under some error, both as regards the delegation to him by the Sanitary Committee of the Town Council of any such instructions and also as regards the intentions and measures which that committee have in prospect. We can hardly conceive of anything much more insulting to the medical profession of the borough in question.

#### MEDICAL OFFICERS OF HEALTH IN CORNWALL.

IT is not without hesitation that we comment somewhat critically upon the attitude of the chairman of the Cornwall County Council towards the medical officers of health within the county, our hesitation being due to the obvious desire of the chairman to get all the information he possibly can with a view to effecting improvements in the state of public health within the county. Mr. Trevail tells the officers that all reports should be in pica type, to save the medical officer of health the trouble of writing five copies—a requirement which we never heard of before. The truth seems to be that the Council want three copies instead of the one they are entitled to. Then, again, Mr. Trevail has compiled a series of questions covering four closely printed sides of foolscap as to which he wants answers. Here, again, he goes entirely beyond anything he has a right to ask, and any medical officer of health who supplies all the details set out, even down to the price paid for notifications, will have a somewhat serious task to perform. Mr. Trevail admits that many of the officers are ill-paid even for the duties they have already to perform, but he holds out the bait to them that, "be the pay as low as it may," the readiest way to get it remedied is to show that the officer has in nowise neglected his duty.

What duty is here referred to we do not quite gather, for the work Mr. Trevail wishes to impose upon them is not amongst their duties. We have much sympathy with Mr. Trevail, and we do not know whose influence it is that has kept the county from appointing a county medical officer of health. But it seems to us that all this is an effort to make up for such an officer by getting the local officers to supply gratuitous information to the chairman, who hitherto has taken upon himself work which the statutory appointment of health officer would have rendered unnecessary. In view of Mr. Trevail's reference to inadequate payment for skilled services, all notion of economy in the failure of the Council to make such an appointment may, perhaps, be set aside.

#### CHOLERA PRECAUTIONS IN THE CITY.

WE find that Dr. Sedgwick Saunders is making preparations for the possible recurrence of cholera next year. He has three proposals under consideration for cholera hospital provision. Two relate to land hospitals, one site being an unoccupied area on the Thames Embankment, the other one in Golden-lane. The third proposal has to do with a floating hospital somewhere between London Bridge and Waterloo Bridge, and to this Dr. Saunders evidently inclines. Subject to the consent of the Conservancy Board and other interested bodies and to the provision of facilities for a landing stage or wharf, this latter scheme seems to be the one which will present fewest difficulties.

#### THE PROGRESS OF SURGERY.

IN opening the Section of Surgery in the Royal Academy of Medicine in Ireland Mr. Edward Hamilton delivered an address on the Progress of Surgery. The most noticeable points in the address were a vindication of the study of anatomy, which, he said, there was a tendency to neglect, on the ground not only of its uses to the surgeon, but as a means of training to the mind. The progress of surgery rested now securely, he thought, on three points—anaesthesia, antisepticism and experimental research. In the matter of anaesthetics his conviction is decidedly in favour of ether for adults and chloroform for children. That his hearers should not be exalted above measure by the great progress of surgery, he reminded them of remaining opprobria, in the fact that cancer and tubercle were still incurable, and that little progress had been made in the cure of syphilis since Hunter said: "if there is such a thing as a specific at all, mercurial is a specific for the venereal disease." He guarded his hearers against two abuses of it—the old terrible overdosage and the present fault of using it timidly and leaving it off as soon as it is about to produce good results. He emphasised the value of "hygienic treatment, good air, good food, early hours, temperance in all things, the Turkish bath, and the blood-making property of cod-liver oil."

#### THE MEALS OF LADY CLERKS.

IT will be generally allowed that the position of young ladies engaged in business in the City of London is not usually one of superfluous ease. The strain of occupation is fairly continuous and prolonged. Its intermissions are brief, not always regular, and limited as a rule to meal times. There need be little wonder, therefore, if those most nearly interested in this matter should feel aggrieved when even in such intervals they cannot obtain that reasonable degree of privacy which is at least desirable if it is not quite essential to comfortable refreshment. In cases where meals are supplied upon the business premises there need be no difficulty. The administration resembles more or less closely that pursued in a large family and the need of separate accommodation is felt but little, if at all. Many public restaurants, again, have been wisely organised so as to provide a distinct room or rooms and attendance in the case

of either sex. A further step in the same direction has recently been suggested—namely, the establishment of a thoroughly respectable house of this class for the use of women only. The necessity of maintaining a reduced dining tariff, however, interposes a difficulty, since it is very questionable whether the ordinary custom of such houses would suffice to make them pay. The suggestion is doubtless worth a trial. For our own part, we cannot forget that much has been done, and more may still be done, by utilising present arrangements to attain the end in view. There is no evident reason why in this, as in other departments of public service, the plan of providing under the same management separate accommodation for men and women should not accomplish all that is expected of a system of distinct establishments. It would, moreover, be much less costly and more certain of financial success than the latter method. The solution of this part of the great food problem is in any case an important matter, for certainly no British workman stands in greater need of timely and wholesome nutrition than do many of these lady toilers.

#### THE LOSS OF THE "BOKHARA."

"LAST seen" and "not heard of again" have now become familiar terms by which we mark in memory the unknown ending of the voyage of many a vessel. Such a phrase, but for the brief record of a very few survivors, has also closed for ever the day's log of more than one strong ship which has left our shores of late but will never again carry freight. The story of the loss of the *Bokhara* has been graphically told by Dr. Lowson. His narrative of almost hopeless conflict and disaster is probably far from unique in the annals of the sea. The like experience has been known by many living seamen. This fact, however, cannot diminish its interest or its instructive reality. Happily we do not in this case hear anything of unseaworthiness or of unskilful management. The unfortunate vessel appears to have been simply overwhelmed by the long-enduring force of a cyclic storm of extraordinary severity. It is well, however, to gather from such a calamity the lessons which it teaches. Not the least of these is that which forbids us ever to despair; and it is, at all events, consoling to register as the one bright spot in all this gloomy history the absence of anything like selfish panic among those who went down with the fated steamer. The composed and manly attitude observed by most of the ship's company and passengers, and not least by the ship's surgeon, in circumstances of the severest trial, is worthy of high commendation.

#### ACCIDENTAL POISONING WITH STRYCHNINE BY AN UNQUALIFIED ASSISTANT.

THE *South Wales Echo* of Nov. 19th contains the report of an inquest on Mary Ann Mellin, of Mountain Ash, who had come by her death from an overdose of strychnia, given in mistake for ten grains of croton chloral for toothache. A post-mortem examination revealed no disease, and Mr. Morgan, county analyst of Swansea, besides detecting traces of strychnia in other organs, found seven-tenths of a grain in the stomach. The unfortunate mistake was made by Mr. Owen Jones, the unqualified assistant of Mr. E. P. Evans. He had been in this position for about five years, and according to Mr. Evans was generally engaged at a branch surgery. We fear this system is very common in South Wales, and is too much recognised by coroners. Mr. Jones had no explanation to give of the mistake save that he did not glance at the label on the bottle, and that he was very seldom in that surgery. Mr. Evans supplemented this information by stating that Mr. Jones had had a fall from a horse about a fortnight ago and had complained of pains in the head. The coroner summed up, and dwelt particularly upon the question of any negligence amounting to culpability or not, and the jury, after consult-

ing in private, found a verdict as follows: "Death from poisoning by strychnine, dispensed in mistake for croton chloral by Mr. Owen Jones. We find that the manner in which the poison was dispensed was negligent and deserving of censure, but we are of opinion that the negligence did not amount to criminality."

#### VACCINATION SUSPENDED AT COVENTRY.

COVENTRY has determined to follow the example of other unions as regards vaccination, and the decision is maintained in the face of some imminent risk of small-pox. Dr. Lynes, the public vaccinator for the town district, has addressed a letter to the guardians stating that during the twelve months which have elapsed since they passed a resolution deciding not to enforce the provisions of the Vaccination Acts only twenty-eight children have been presented at his public station, whereas in the twelve months preceding that decision the corresponding number was 577. The newspaper publishing the proceedings of the guardians simply states that no action was taken on the letter. Apparently nothing can now be done but to await the result of the widespread neglect which is being maintained in many parts of the country.

#### INSANITARY AREAS IN LONDON.

THE improvement of three insanitary areas in St. Pancras, which had been represented by the medical officer of health of the district, Dr. Sykes, has been the subject of correspondence between the London County Council and the St. Pancras Vestry, the latter body not unnaturally desiring the Council to effect the improvements at the cost of London as a whole, while the Council, on the other hand, proposed to undertake this duty in respect of one insanitary area and to leave the other two to the vestry to deal with. Application was made to the Home Secretary for arbitration soon after the representations were made, and an inquiry was opened. It was then found that some doubt existed as to the size of one of the areas, and the inquiry was adjourned with a view to further negotiations between the two bodies interested. The vestry, not being satisfied with the proposals of the Council to which we have just referred, has now asked the Home Secretary to reopen the inquiry. It is stated by a contemporary that the death-rates in these areas last year were 44, 52, and 61 per 1000, as against 20.6 in the parish generally.

#### POISONS IN THE GARDEN.

A CONTEMPORARY has lately noted the number of poisonous plants and weeds existing in an ordinary garden, and gives the grave warning that "care should be taken that they are not munched or sucked by children." Without a doubt the poisons are there, and will produce bad results if consumed. But happily very many of them are characterised by an unpleasant taste, which diminishes the temptation to tamper with the harmful plant. All the care in the world, however, is probably inadequate when it is a question of dealing with the experimental tendencies of a young child. General warnings of the probable discomforts may to a certain extent check its curiosity, but then these warnings should embrace all plants, and not be confined to sundry special instances, thus leaving the child to infer that, with these exceptions, it is safe to eat the other members of the vegetable kingdom. It would certainly be safer to indicate the few plants which may serve for field feasts than to attempt to impress upon a child the somewhat lengthy list of those to be avoided. In the country, however, and among the children of the poor, all rules and regulations are apt to be set at naught, and it is to be feared that each child learns wisdom, as its elders have done, by bitter experience. The results of one experiment with a sufficiently nauseous plant are usually enough to convince a child of the

unwisdom of personal experimentation and to teach a lesson far more permanent than any ever taught by an anxious parent. Without recommending this mode of instruction, which is not devoid of risk, it is, nevertheless, that by which a respect for the medicinal and toxic effects of plants is most generally acquired.

#### EXCLUSION OF MEDICAL MEN FROM MONTE CARLO.

OUR contemporaries comment on the exclusion of medical men and their wives from the casino of Monte Carlo. We cannot profess to regret this, and only wish that the authorities would extend their refusal to all other respectable people. It is to the credit of the members of the English profession practising in the principality that they approve of this exclusion. They are right in regarding it rather as a compliment and an advantage to the profession than otherwise—a compliment because it implies that their presence might have a deterrent effect on gambling by patients who are under medical discipline; an advantage as removing them from a place of temptation and excitement where a professional man has no business to risk his hardly earned and modest gains.

#### BACTERIOLOGY AT KING'S COLLEGE.

It is now six years since bacteriology has been regularly taught at King's College, and a special report has recently been presented to the council showing the work that has been done in the laboratory during that period. The laboratory was established to provide accommodation for practical instruction and for giving systematic courses of lectures, as well as for granting facilities for original research. Medical men in practice, medical officers of health, analysts, medical and veterinary officers of the services have so readily availed themselves of its advantages that 419 have already made use of it either for instruction or research. A few of these have previously been connected with the College; a great number have been qualified medical men from the United States; others have come from New South Wales, Queensland, Tasmania, China, India, Ceylon, Chili, the Cape of Good Hope and Trinidad; whilst many have been medical officers on leave from foreign service, showing how extensive a demand existed for such a laboratory and such teaching. About forty workers have entered under Professor Crookshank's superintendence during the present winter session, and an evening-class course is in full operation under the direction of the demonstrator, Mr. Hewlett. Numerous researches have been made on actinomycosis, tuberculosis and other diseases attributed to micro-organisms, and a list of these is included in the report.

#### MATERIA MEDICA IN SCOTLAND.

PROFESSOR FRASER, in his very thoughtful and well-considered introductory lecture which was published in our last issue, drew attention to the anomalies introduced by the changes in the Medical Ordinance which became law on Aug. 5th of this year. These changes were referred to in our columns at the time, but the difficulties are emphasised by Professor Fraser with copious illustrations. Briefly they refer to the position in the curriculum which the subjects of therapeutics and pathology should occupy. Professor Fraser traverses the well-worn ground of the relations between pharmacology and physiology and between therapeutics and pathology, and he indicates the practical impossibility of giving a satisfactory account of the actions of many drugs without frequent reference to pathological conditions. According to the report of the Scottish Universities Commission candidates shall not be examined in pathology until after they have passed an examination on the therapeutic applications of medicines, hence the teachers of materia

medica will, to use Professor Fraser's expressive phrase, find it necessary "to make bricks without straw." Pharmacology and therapeutics to be satisfactorily taught must go hand in hand, but they should equally find their place in the curriculum when from the previous education of the student in physiology and pathology they may be properly appreciated. So far as teaching is concerned this fact has been recognised by the Conjoint Board of the Royal Colleges of Physicians and Surgeons, although, for the purposes of examination, pharmacology and therapeutics are to be divorced, and an attempt at reparation of the evil is made by a new and arbitrary definition of pharmacology. Still the subjects will be taught at the same time, and the outlook is not, therefore, so gloomy as in Scotland, where, although they are linked together, the student is apparently encouraged to attempt the study with wholly inadequate previous knowledge. The new regulations seem so disastrous that it is to be hoped they will shortly undergo revision.

#### TYPHUS FEVER AT DUNDEE.

THE outbreak of typhus fever at Dundee appears to be still spreading. Twenty-eight cases of that disease are now isolated in hospital. As an index of the insanitary conditions surrounding those attacked, it may be mentioned that a certain family attacked by the disease consisted of eleven persons living in a one-roomed dwelling. The negotiations for a "reception house" have unfortunately fallen through, but it has been arranged that those who have been in contact with the sick shall be kept under strict medical supervision. The School Board has decided that there is at present no need to close certain schools in the town, but exclusion of scholars from infected homes is being rigorously carried out. With these and other sanitary precautions, such as careful and early disinfection of houses and clothes, it is hoped that the epidemic may be held in check.

#### HYDRO-THERAPEUTICS IN ITALY.

AN ever-growing place in the resources of therapeutics is asserted by mineral waters, especially when taken amid the natural surroundings and under the climatic conditions of the locality whence they spring. Italy is peculiarly rich in such waters, the virtues and uses of which her inhabitants seem to have better appreciated and more effectively recognised in ancient than in modern times. While her clinical medicine has fairly well kept pace with the advance of science and practice, while every appliance for the study of disease and for the cure and comfort of the patient has with tolerable completeness been adopted in her hospitals, she is still far behind her less favoured contemporaries in the development and utilisation of her superabundant mineral waters. She still has the mortification of seeing the tide of invalid travel going past, or even across, her frontiers *en route* to health resorts inferior in most natural conditions to many of her own, the attractions to the former being their undoubtedly better organisation and equipment from a medical point of view and their immeasurable superiority in hotel accommodation, cuisine, attendance and general comfort. This source of revenue, so highly appreciated and effectively utilised by Switzerland, Austria, Hungary, Germany and France, Italy has at last begun to recognise; and, at her wits' end to improve her finances without further recourse to taxation, she is bethinking herself of the mine of wealth placed within her reach if only she will take the trouble to tap it. Of late years, accordingly, there have been held periodical meetings of the profession at or near the great mineral water resorts, with a view to the better organisation of these and the diffusion of their merits over a more extended area, while the Government has come to the aid of the more enterprising of them—Montecatini, for example—

by annual subventions and official superintendence and control. This week the Associazione Medica Italiana d'Idrologia—for such is the central association called—holds its annual sittings in the Palazzo Vecchio in Florence, and a glance at the agenda paper will give some notion of the place hydrology now holds in Italian therapeutics, and, by implication, of the richness of the country in the waters which such treatment calls into play. Dr. G. S. Vinai, for example, will read a paper on the Influence of Hydro-therapeutic Operations on Muscular Fatigue; Professor M. Bossi will discourse on Gynæcology and the Therapeutics of Marine Hydrology; Dr. F. Canova will draw the attention of the meeting to the excellent results he has had from Hydro-therapeutics in *Tabes Dorsalis*; Dr. E. Morra's special contribution will be on the Alpine Colony for Poor Children at Camandona (Piedmont), in which climatic goes hand in hand with therapeutic treatment; Signor Chiari will take up the theme of Artificial Mineral Waters, and Dr. Vinai will supplement his first paper by two others on the Study of the Cerebral Circulation consequent on the Douche, and the New Bath of Artificial Carbonic Acid as practised in the Hydro-therapeutic Establishment at Andorno (Piedmont). Much that is novel and practical is to be expected from the reading and discussion of these papers, as the names of their authors, well known for previous good work in the same field, will at once signify. They will indicate, we hope, a fresh stage reached in the appreciation, public and professional, of Italy's long-languishing, but now actively resuscitated, interest in her mineral-water resources, possessing, as these do, more than one special advantage, prophylactic as well as therapeutic. At the close of the sittings it was intimated that the Association would hold next year in Rome an International Hydrological Exposition, at which, in separate sections, would be exhibited specimens of all the natural mineral waters of Italy, apart from the artificial waters of the country, which were also to be on view. If, as is likely, this Exposition form part of the larger "Esposizione" under the auspices of the International Medical Congress to be held at the same time and place, it will bring Italy's resources in this branch of therapeutics more fully before the world than they have yet had an opportunity of effecting.

#### POISONING BY PTOMAINES.

MR. E. WOODGATE, deputy coroner, held an adjourned inquest at Old Brompton touching the death of Lieutenant William Huddleston, R.E., who died at Chatham Barracks on Oct. 24th. As we mentioned last week the officer died somewhat suddenly after partaking of sardines. Dr. Stevenson of Guy's Hospital, who made an analysis of the remaining contents of the tin and also of the stomach and other organs of the deceased, deposed that in his opinion death was due to an animal alkaloidal poison. His examination showed that the poison was contained in some but not in all of the sardines; for whilst a mouse which was fed on one of the fish soon died, a second fed on another was not harmed. From the vomit a substance was extracted which, when injected, killed a rat. From two sardines he obtained only  $\frac{1}{16}$  grain by alkaloidal processes, but this sufficed to kill a rat. The tin which contained the sardines was bright and clean; moreover, it is clear that the symptoms, both in their degree and nature, differed from those of metallic poisoning. Dr. Stevenson could detect no known mineral or vegetable poison. There was, then, suggestive evidence that the death was not due to either of these poisons, and positive evidence that the bodies of some of the sardines contained a substance endowed with lethal properties. The most remarkable fact in the case is that such a small quantity of the poison was quickly destructive to the life of the rat into which it was injected. Dr. Stevenson believed that the decomposition took place before the tinning and that only

certain of the fish were affected. Three hypotheses present themselves as possible explanations of the poisonous properties of the fish:—1. The production of a toxic agent by metabolic changes of a vital or physiological nature—a kind of secretion, as it were, by the living fish. This is extremely improbable, for otherwise cases of poisoning would be more common than they are, and before now sardines would have fallen into disrepute and, to a great extent, into disuse. 2. A fermentative process in the dead fish, by means of which an animal alkaloid was evolved from the decomposition. This of course would be of a peculiar nature, and not a mere putrefaction with evolution of stinking gases. It may be here noted that, whilst Dr. Stevenson detected an odour in the tin somewhat different from what is ordinarily present, he admitted that had the sardines been put on his breakfast table he would have partaken of them. The theory in question would seem to us to be the only tenable one, and to exclude the third—viz., that shortly before capture the fish had ingested some poisonous body. The subject of ptomaine poisoning is extremely intricate, and as yet we have but glimpses of the exact number, nature and properties of the toxic bodies. Further research, we trust, will reveal what is now hidden, and so guide us to preventive and curative treatment. We have to acknowledge Dr. Stevenson's courtesy in giving us valuable information.

#### METROPOLITAN POLICE SURGEONS' ASSOCIATION.

THE fifth annual meeting of the members of this Association, under the presidency of the chief surgeon, Mr. A. O. MacKellar, F.R.C.S., was held on Thursday, Nov. 24th, followed by a dinner at the Criterion, Piccadilly. Between sixty and seventy were present, and as guests were Sir John Bridge, representing the metropolitan police magistrates; Mr. A. C. Bruce, Assistant Commissioner, representing the Commissioners of Police; Dr. Danford Thomas and Mr. Braxton Hicks, representing the coroners of the metropolis; Mr. Holmes, formerly chief surgeon; Canon Boger and many others. At the meeting the annual report was submitted and the Association was shown to be in a satisfactory condition in regard to addition of new members. Many points that had been before the Council during the year, of great importance both in the interests of divisional surgeons and the public, were recapitulated, and the treasurer's report showed the society to be in a sound financial position. The honorary secretaries announced that nearly all the divisional surgeons of the metropolitan police were now members of the Association. The members of council for the ensuing year were elected. Mr. Phillips was elected a vice-president, with the understanding that he would assent to continue the duties he had heretofore filled as treasurer, and Dr. Yarrow and Mr. Spurgin were re-elected honorary secretaries. At the dinner, after the usual loyal toasts, the President, Mr. MacKellar, in alluding to the toast of the evening—viz., "The Association"—happily compared it to a new-born infant who, having gone through all the stages of birth—dentition, vaccination and all attendant ills of childhood—was now fairly launched on its legs as a full-grown child able to take care of itself, and obedient and loyal, moreover, to its parents, its foster parents and its nurse, and giving promise of a vigorous manhood and a useful life. In responding to the toast of "The Commissioners of Police and Assistant Commissioners," Mr. Bruce alluded to the great pleasure it gave him to be present at so representative a meeting of a body of gentlemen so essential to the well-being of the police and the public as the divisional surgeons of the metropolis, than whom he felt assured a more loyal body never existed, and he assured those present that the Commissioner was always pleased to take into consideration any points of importance emanating from them

and was desirous to work hand in hand with them in all matters pertaining to the good of the police service. Sir John Bridge responded for "The Visitors," and gave a humorous illustration of the want of gratitude he found on the part of those coming under his jurisdiction; while, in returning thanks for the toast of "The Coroners," Dr. Danford Thomas said that, without disparagement to the medico-legal acquirements of other medical men, he was always pleased to find a divisional surgeon present as a witness, as he then felt assured he would have good and reliable evidence. Mr. Braxton Hicks also alluded to his sympathy with medical men from his own position as a son of one of the profession. The musical arrangements were under the direction of Mr. Herbert Schartau, who, with his part singers, enlivened the evening with an admirable selection of music, and a most enjoyable evening was spent.

#### THE TRURO INFECTIOUS HOSPITAL.

THE guardians of the Truro Union are very angry because the Local Government Board refuse to sanction the lease of an old parish workhouse to the city authority, as an infectious hospital, for a term of fourteen years. We believe that during the term in which that building has already been so used part of the premises have been too dilapidated to serve as a hospital, and that the buildings about on a public thoroughfare. We trust that, however the intending lessors may look at the matter from a financial point of view, the sanitary authority will see that the day has come when isolation, to be effective, must be carried out in a proper building, properly situated and sufficiently attractive to ensure the co-operation of the medical profession and of the public.

#### DIPHTHERIA AT CARDIFF.

No less than twenty-six cases of diphtheria were notified at Cardiff during the third quarter of the year, of which ten were fatal. This is equivalent to a mortality rate which, though considerably above that of the five previous corresponding quarters, is only slightly above the rate in the thirty-three large towns and much below that of the metropolis.

#### TRAUMATIC HERNIA OF THE LUNG.

TRAUMATIC HERNIA of the lung is a very rare accident, and experience in its treatment falls to the lot of very few practitioners and is very slowly acquired. Every case, therefore, is worthy of record and careful consideration. Dr. E. Massart of Honfleur has recently recorded an instance of this injury. It occurred in a robust, healthy man, thirty-eight years of age, as the result of a stab-wound in the seventh left intercostal space, a little behind the anterior axillary line. The protruding lung formed a swelling in the wound the size of half a hen's egg; it was smooth, of a rosy colour, irreducible, crepitating under the finger, and not altered in size by the movements of respiration. The wound was fourteen hours old when Dr. Massart saw it, and fragments of dirty cloth were adherent to the wound and the lung. The patient complained of severe pain in the part, and his respiration was short, rapid and embarrassed. An attempt to reduce the hernia having failed, its base was transfixed with a needle carrying a double strand of catgut, with which it was tied in two pieces. The projecting mass was then cut away and the stump reduced into the pleura. The external wound was then closed. Rigid antiseptic treatment was carried out. The result was very satisfactory. The man made an excellent recovery without either pleurisy or pneumonia, and the only complication was slight superficial suppuration in the wound. Dr. Massart justifies his line of treatment on the ground of the great danger of returning an infected lung into the pleura. The case is of great interest as showing the tolerance of the lung of surgical interference, and

has a bearing upon the possibility of excising portions of lung for tumour. It is also worthy of note that there was no collapse of lung or pneumothorax after the operation. Those who are accustomed to operate upon the pleura will not be surprised at this, for they have learnt that the general opinion on the danger of opening the pleural cavity is much exaggerated.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Budapest.*—The Professorial Senate of the Medical Faculty has elected Dr. Ludwig Markusovszky an honorary member.

*Coimbra.*—Dr. Augusto Antonio da Rocha has been appointed Professor of Forensic Medicine and Hygiene.

*St. Petersburg (Military Medico-Chirurgical Academy).*—Dr. N. Sokoloff has been appointed to the chair of Special Pathology and Therapeutics; Dr. Bogoluboff has been recognised as *privat-docent* in Medicine.

*Saragossa.*—Dr. Luis del Rio y Lara of Cadiz has been appointed to the chair of Histology and Pathological Anatomy.

*Vienna.*—A new clinic for Hydro-therapeutics has been established under the direction of Professor Winternitz.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Fernando Augusto de Andrade Pimentel de Mello, Professor of Forensic Medicine, Public Hygiene and Sanitation in the University of Coimbra.—Dr. Johann Belky, Professor of Forensic Medicine in the University of Clausenburg, at the age of forty-one.—Dr. Karl Friedinger, formerly director of the Lower Austrian Lying-in Hospital and Foundling Hospital, at the age of seventy-two.

As will be seen from the report which we publish on another page, the application of the Royal British Nurses' Association for a charter of incorporation was again considered by the Special Committee of the Privy Council on Monday last, when, at the conclusion of the arguments, their lordships reserved judgment. At present, therefore, it is too early to judge of the success of the application, and any comments that we may have to offer upon this latest phase of the long discussion will be more timely later on, when we are in a position to record the judgment at which the Privy Council has arrived.

THE next meeting of the Odontological Society of Great Britain will be held at Leicester-square, on Monday, Dec. 5th, at 8 P.M., when a paper will be read by Dr. Sims Woodhead on "Inflammation in Bone"; and casual communications, by Mr. Ackery, on a case of "Complete Loss of the Teeth from Dental Caries in a lad aged sixteen years," and by Mr. A. W. Barrett, on "Adhesion between Roots of two upper Molar Teeth, and extraction of both simultaneously," will be given.

WE understand that it has been decided that the Sir George Buchanan Presentation Fund shall be devoted to the founding of a gold medal to be given biennially or triennially for distinguished services rendered to sanitary science; that the Royal Society will be requested to award the medal Sir George Buchanan will be asked to define the conditions under which the medal will be given.

ON Tuesday, Nov. 22nd, Dr. W. J. Smyly, Master of the Rotunda, performed the operation of symphysectomy, the first of the kind, we believe, in the United Kingdom. At the time of going to press mother and child were doing well.

MR. WILLIAM CARMICHAEL McINTOSH, M.D., F.R.S., Professor of Civil and Natural History in the University of St. Andrews, has been appointed a member of the Fishery Board for Scotland.

WE understand that Dr. T. D. Savill has gone to Warrington at the request of the Royal Commission on Vaccination to investigate the epidemic of small-pox in that town.

HER ROYAL HIGHNESS PRINCESS MARY OF TECK has consented to become "patroness" of the Central London Ophthalmic Hospital, Gray's Inn-road, W.C.

## THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

FRIDAY, NOV. 25TH.

THE Council resumed their sitting, Sir Richard Quain, President, in the chair.

### *False Death Certificates.*

Dr. MAC ALISTER, seconded by Dr. LEBECH, moved, "That the solicitor to the Council be requested to communicate to the registrar-generals of the three divisions of the United Kingdom the Council's opinion that it is of the greatest public importance that they should take proceedings under the Registration Acts in all cases in which it comes to their knowledge that a medical practitioner has given a false certificate of death."

Dr. GLOVER asked whether the President or registrar had received, since the last meeting of the Council, any notices from coroners of cases in which false certificates of death have been given by registered practitioners, and if so, how many, and what was the explanation of such notices not being submitted to the consideration of the Council.

Mr. FARRER, solicitor to the Council, replied that there had been three cases since the last meeting in which irregularities were complained of. Two of these cases had been brought to the notice of the Registrar-General. In regard to one of them he had told him (Mr. Farrer) that the irregularities did not amount to a false certificate, and as to the other it was still under his consideration. The third case, it was believed, would be explained by the person accused. But in none of these cases had there been, to the best of his recollection, any complaint by the coroner. He might add here that the Registrar-General had peculiar powers of ascertaining what were false certificates by going to a court of law—powers that the Council were without.

Dr. MAC ALISTER explained that with a conviction under the Registration Acts before them it would be easy for the Council to take proceedings against the practitioner.

The PRESIDENT expressed his approval of the motion, which, he thought, would not be without effect upon the Registrar-General.

The motion was then agreed to.

### *The Council and the Society of Apothecaries of London.*

Dr. BATTY TUKER opened the discussion on the report of the Education Committee with regard to the position of the examination in Arts of the Society of Apothecaries of London. He expressed his regret at the absence of the chairman of the committee, Dr. Leishman, and his hope, which he believed to be well founded, that the Council would find him in his accustomed place at the spring meeting. No one who had studied the minutes of the Council would have failed to notice that from the earliest years of its existence it had taken great interest in the matter of preliminary education. They would find scattered throughout volumes of minutes recommendations all tending to improve the preliminary examinations of medical students. Their attention was drawn to the subject very strongly by their late President. For many years the Council had been liable to pressure from within, but at last it came to pressure from without, for on Nov. 28th, 1890, a communication was forwarded by the Secretary of State for War to the registrar of the Council, intimating that he had had before him a report

from the Director-General of the Medical Staff of the manifest deficiency in orthography prevalent amongst the young medical officers of the army, and to inquire whether, under those circumstances, the Council might not insist upon a more efficient preliminary examination of the student before he entered a medical career. This communication was referred to the Education Committee, and one of their recommendations was to the following effect:—"That the examinations enumerated in Group II. of the list of preliminary examinations at present recognised by the Council be omitted from the list, except those conducted by the College of Preceptors, by the Educational Institute of Scotland, by the Scotch Education Department for leaving certificate and by the Intermediate Education Board of Ireland." The examinations referred to under Group II. were that of the Apothecaries' Society of London, examination in Arts; that of the Royal Colleges of Physicians and Surgeons of Edinburgh, preliminary (combined) examination in general education; that of the Faculty of Physicians and Surgeons of Glasgow, preliminary examination in general education; and that of the Royal Colleges of Physicians and Surgeons in Ireland, preliminary examination." The gist of the recommendation was that no professional licensing body should conduct the preliminary examinations. On June 1st, 1891, the Council in committee adopted the following resolution, "That it be recommended to the bodies in Group II. enumerated in the note to Clause 4 of the Education Committee's report to discontinue the holding of their preliminary examinations in Arts." When the question was reopened on May 24th, 1892, the following resolution was come to—namely, "That the case submitted by the Society of Apothecaries of London to counsel, and the opinion given thereon, together with the case submitted by the President to Mr. Muir Mackenzie, and his opinion as printed on pp. 36 to 40 of the minutes of the present session of the Council, be referred to the Education Committee for consideration and report." What he had said explained the circumstances in which the reference was made to the Education Committee. As to the opinions he did not think it was necessary to go into them. The case submitted by the Society to Messrs. Rigby and Leveson was intended to test the validity of a recommendation of the Education Committee to the effect, "That, in the event of any of the examinations in Group II. of the Council's lists of preliminary examinations in general education being continued after Jan. 1st, 1892, they should not be accepted by the Council as valid preliminary examinations, except in relation to the professional examinations of the particular bodies which conduct them; and that they be indicated in the Council's list of recognised examinations." In the judgment of the committee the opinion was sound so far as it bore on the recommendation. Under existing circumstances the Council could not limit the privileges accruing to the student who passed a recognised preliminary examination. Such power of limitation could be exercised only by individual bodies. The committee openly and freely admitted that it was an error to advise the Council to adopt measures which it was not entitled to carry out. Had the statement and opinion stopped short at this point the duty of the Education Committee would have been fulfilled by the above expressions of opinion, but study of the documents made it impossible to refuse two inferences: (1) That the Society of Apothecaries takes its stand on the opinion of counsel, and that it proposes to act on what it is advised are its legal rights in respect of the conducting of a preliminary examination in Arts; and (2) that the Society challenges the power of the Council to insist on the maintenance of the Students' Register. He had some hope that the Council might receive from the representative of the Society some intimation that those inferences were false inferences; but apparently no such intimation could be given. The committee pointed out in their report that should the Society persist in conducting a preliminary examination it would do so in direct opposition to a recommendation of the Council. The Council based the recommendation that the examinations of certain bodies in Group II. should be omitted on the general and often expressed desire that the standard of general education should be raised; on the evidence supplied by public departments that some measure in that direction was urgently called for, and on the admirable spirit which had invariably actuated the various bodies to accept recommendations tending to the general good of the medical profession. Most of the corporations had anticipated the recommendation in question or acceded to it as soon as it was placed before them. The

Society of Apothecaries stood alone in raising legal objections to the adoption of a salutary regulation. He fully admitted that the Royal College of Surgeons of Ireland held it inexpedient to give up their preliminary examination at present, but their document was so mildly worded that there could be no doubt that in a very short time, or as soon as possible, they would relinquish the examination. He awaited with very considerable interest the statement of the representative of the Society of Apothecaries with regard to the reasons for adhering to this examination. For his own part he had not been able to form a theory as to what it was likely to be. The case presented to Messrs. Rigby and Leveson by the Society stated that, "It may be assumed that the standard and quality of the examination held by the Society have not been called in question by the Medical Council." The Council, said the committee in their report, had not called in question the standard and quality of the preliminary examinations of any of the bodies directly; but by its formal recommendations that certain of the bodies should discontinue such examinations, the Council must be held to have reflected inferentially on standard and quality. It was forced on the committee to submit that the following figures supplied ground for criticism as regarded the only body formally resisting the recommendations. They were taken from the table showing results of preliminary examinations for the last five years, and contrasted the results of the examinations of the Apothecaries' Society and those of the College of Preceptors :-

Year.	APOTHECARIES' SOCIETY OF LONDON.			COLLEGE OF PRECEPTORS.		
	No. examined.	No. passed.	No. not passed.	No. examined.	No. passed.	No. not passed.
1887	755	588	167	1352	508	844
1888	736	570	166	1339	482	857
1889	652	524	128	1281	464	817
1890	692	471	221	1350	388	962
1891	781	631	150	1452	496	956
	3016	2784	232	6774	2338	4436

These figures showed a percentage of rejections at the Apothecaries' Hall of 23 and at the College of Preceptors of 66.5. If the widest field of comparison were taken and the results of the preliminary examinations conducted by all the bodies in Great Britain and Ireland, as scheduled in the minutes, were analysed, the percentage of rejections in 1890 was found to be upwards of 37 and in 1891 nearly 40. The Committee submitted these figures without comment. The conclusion of the Committee was that the Council should maintain the attitude it had all along assumed as regards the Students' Register. They further deemed it advisable that the Council should, in order to ensure that registration was fully carried out, instruct the registrar and branch registrars for Scotland and Ireland to ascertain whether the names of all applicants for registration in the Medical Register had appeared in the Students' Register, and, in the event of any name not having so appeared, to intimate the fact to the Council, together with the name of the body from which the qualification had been obtained. If in the carrying out of this direction it was shown that the registration of students was systematically neglected, the Council would be in a position to consider what further means should be adopted to secure efficient registration. He would now read the recommendations prepared by the committee. They were as follows: (1) That the Council address to the Society of Apothecaries of London a further expression of opinion that the discontinuance of the Society's examination in Arts would be for the public good. (2) That, in the event of the Society of Apothecaries of London not being prepared to intimate to the Council that its examination in Arts is to be discontinued at the end of the present year, the Council attach to that examination in the Council's list a note stating that "the Council has recommended and recommends that this examination be discontinued." (3) That the Council instruct the registrar, and the branch registrars for Scotland and Ireland, to ascertain whether the names of all applicants for registration in the Medical Register have appeared in the Medical Students' Register; and, in the event of any name not having so appeared, to intimate the fact to the Council, together with the name of the body from which the qualification had been obtained. (4) That a copy of these recommendations, with the report of the Education Committee on which they are founded, be sent to each licensing body.

The Council decided to discuss the recommendations separately.

Dr. BATTY TUKE, seconded by Mr. WHEELHOUSE, moved the adoption of the first recommendation.

Mr. MACNAMARA referred to the state of things in Ireland in regard to preliminary examinations.

The PRESIDENT reminded him that the recommendations before the Council only dealt with the Apothecaries' Society of London.

Mr. MACNAMARA: I thought it only right that Mr. Carter should know that he is not the only black sheep, and the reason why.

Mr. BRUDENELL CARTER said it would perhaps be right that he should endeavour to bleach himself as soon as might be. He rose under circumstances of peculiar difficulty, because in the first place the report of the committee did not come into his hands until yesterday morning, and the interval which had elapsed had not been sufficient to allow him to have any communication with the authorities of the Society of Apothecaries or to ascertain what their feelings might be upon the subject matter of the report. The observations he proposed to make must not, therefore, be taken as those of the Society, but simply as the expression of his own personal opinion. The second difficulty under which he laboured was that, being a member at once of this Council and of the Society of Apothecaries, jealous of the honour and careful of the interests of both, he should greatly deplore if any injudicious word of his were to do anything that might promote or otherwise than retard or prevent the possibility of a collision between two bodies, both of which he held in the highest and most unflinching respect. But those difficulties were diminished as far as his own perception of them went by the circumstance that he had never before engaged in any dispute in which the merits of the question were so absolutely and entirely upon one side and the demerits upon the other. In his humble opinion, in this controversy justice, legality and expediency were alike mustered on the side of the contention of the Society of Apothecaries, and on the side of the Education Committee nothing. He could hardly understand what the Education Committee had to do with this particular matter. He could hardly understand how they contrived to escape from the scope and limits of their proper duties, and to get into this particular galley, in which they were found pulling so hard an oar. The result of the reference to the Education Committee was the brilliant suggestion that the orthography of young medical men would be improved if the preliminary examinations in Arts were conducted no longer by the medical corporations but by the College of Preceptors, a remedy which certainly was not infallible, because in the present session, among four gentlemen who had been reported to the Council as having failed in orthography, one had been passed by the College of Preceptors. It seemed to him a monstrous proposition that a body which was fit to be entrusted with the control and direction of the qualifying examinations for entrance into the medical profession was not fit to be entrusted with the control and direction of preliminary examinations. If that suggestion came to the Council from any external source he was sure they would unite in repudiating it in the most vigorous possible manner. Upon a former occasion Dr. Heron Watson quoted some previous resolution of the Council to the effect that such a change would be likely to be beneficial. Such a resolution did not modify his opinion. He had abandoned the practice of ancestor worship, and the mere fact that at some remote period a majority of this Council or of a former Council, he knew not how constituted or in what circumstances, passed a resolution which appeared to him to be extremely foolish did not in the least modify the opinion which he held upon the present question. He could not see that the Society of Apothecaries would be justified in waiving their examination even on the plea that it might be conducted by a wholly undistinguished body like the College of Preceptors. When this resolution was passed originally by the Council there were two classes of corporations to whom it might be said to have referred. There were those who had a number of candidates, which was not sufficient to make the examination a matter of the smallest importance to them, and there were those who had a considerable number of candidates and to whom the examination might be of importance. The former class were quite ready to relinquish a troublesome and unprofitable task. Some of them even anticipated the recommendation of the Council and had beforehand ceased to do what they did not care to continue doing. But the Society of Apothecaries stood in a

totally different position. Its examination in Arts had been conducted upon its present lines for more than thirty years. It was resorted to annually by increasing numbers of students, both within and without the ranks of those who intended to join the medical profession, and it was a source of definite remuneration to the Society. In those circumstances the rulers of the Society were not free to act precisely according to their own inclinations. They occupied a fiduciary position. They were bound in honour and duty to protect the privileges of the Society, and to hand down intact to those who came after them all the rights which they had received from their predecessors. With regard to the fitness of the Society to direct and control such an examination as this, it was perhaps sufficient for him to say that among its rulers was Professor Henry Morley, and he thought if they were to place Professor Henry Morley in one scale and the College of Preceptors, Fellows, Members, Licentiates, and the whole of the examining apparatus in the other, the College of Preceptors would kick the beam. In this condition of things the Society determined to ascertain their rights, and for that purpose took counsel's opinion. As to the inferences drawn by the committee, they appeared to him to be absolutely unfounded. The Society had expressed no intention of any kind. It had raised no legal objections, it had merely inquired whether it was possible to raise them. Then the committee spoke about inferential reflection. Surely it was the business of the Council not to endorse inferential reflection. A door must be open or shut. An examination must be sufficient or insufficient. If it was insufficient it was the duty of the Council to make proper representations to the body conducting it, and if those representations failed in their purpose to approach the Privy Council. The figures that were referred to in the report were absolutely worthless. They all knew that a high rate of rejections in an examination was no test whatever of its value. Then they came to the last recommendation, of which he could only say that it positively bristled with libellous suggestions and defamatory innuendoes. He could not tell what course the Society might be disposed to take. He knew quite well what course he should be prepared to take if he were one of their rulers, and he felt sure that without legal advice the Council would act most unwisely if they in any way endorsed the sentences which they had before them. He begged to move, "That Section A (the portion relating to the Society of Apothecaries) of the report and recommendations of the Education Committee be referred to the Examination Committee for consideration, with an instruction to confer with the legal advisers of the Council before sending in their report."

Mr. COLLINS formally seconded this amendment.

Dr. MACALISTER protested very strongly against the amendment. The whole subject of preliminary education had been carried through all its steps by the Education Committee, and to refer this matter to another committee could only result in the resignation of the Education Committee. The object of the Council in this connexion was to raise the standard of preliminary education. Although they got a new stimulus from the strong letter of the Secretary of State for War, that was by no means the beginning of the affair—that only showed they wanted hurrying up. When they had a list of seventy or eighty examinations, all supposed to qualify students for entrance into the profession, and when they were told that these examinations did not keep out the unqualified, the only possible course that could present itself to any committee charged to look into the matter was to arrange them into a comparative order of difficulty or searchingness, and to cut off those at the bottom of the list. The Education Committee had proceeded upon that plan. He said deliberately that of all the examinations that students passed in England, that of the Society of Apothecaries was the one which offered the least and the weakest guarantee of efficiency in the matter of preliminary education. It was notorious that this was the easiest examination, and that students who were plucked again and again in other examinations came up to the Society of Apothecaries and returned with registration certificates, which of course defeated the object of those who wished to see them attain the highest standard of education.

Dr. ATTHILL said he was in a difficulty, for while he held strongly that the medical corporations would be far better if they were free from the charge of these examinations, he was not able to say that on behalf of those who sent him to the Council. He felt very unwilling to vote for the amendment, because he was told it would be looked upon as a censure upon the committee.

Mr. BRUDENELL CARTER said he had not the slightest intention of throwing a slur upon the Education Committee. He merely thought the Examination Committee was the proper committee to deal with the question of examinations. He would be happy to make the reference to the Education Committee.

Sir JOHN SIMON thought Mr. Brudenell Carter had pushed the necessity for legal advice too far. In point of fact, the policy advocated by the Education Committee had been before the Council time after time. The original intention was that men entering the profession should have the school education of gentlemen, and when the Council took up the matter they at once said the way to ensure that was that the people who looked after the general education of the country should certify the students. The bodies generally had accepted the view that the Council did not want a special examination adapted to medical students, but the general standard of good school education in the country, and had retired from the position of being special examiners. It was only local considerations that prevented the bodies in Ireland from adopting this course in the meantime. He had often stood on the side of the Society of Apothecaries, but on this occasion he thought they were wrong. They would be wrong if the examination related only to their own licentiates, but he confessed for himself that if that were all, he should not be very strict in watching whether they complied with the rules of the Council. When, however, it came to the Society pretending to meet the world at large and to be an examining body in Arts, they must surely draw the line, and he saw no alternative but to support in substance the view taken by the Education Committee.

The PRESIDENT said that if the recommendations of the committee were carried, there was no doubt they would lead to another lawsuit that would be as long and expensive as that in which the Council were already engaged. He was sure of this, that the Society of Apothecaries would not give up their privileges unless they were compelled. In these circumstances he would be glad indeed if counsel's opinion were obtained before the vote was taken.

Dr. HAUGHTON thought Mr. Brudenell Carter had thrown away his case by attacking a body about which he knew nothing—namely, the College of Preceptors. This body was as much respected among schoolmasters as the Council was among medical men.

Sir DYCE DUCKWORTH said he could not agree with the President. They were not there to be frightened by the terrors of the law or by lawyers. They were there to do their duty.

Mr. BRUDENELL CARTER again disclaimed having any authority in this matter to speak for the examination of apothecaries.

On a vote being taken the amendment was lost.

Sir W. TURNER suggested that the recommendation in its present form was too wide. All the Council had to do with was the examination of the Society so far as it appertained to the entrance examination to the medical profession.

Dr. MACALISTER explained that the title given to the examination by the Society was the "Preliminary Examination in Arts for medical students."

It was agreed to incorporate this title in the recommendation, which, thus amended, was put to the Council and adopted.

Dr. BATTY TUBE then moved the second recommendation of the committee.

Sir W. TURNER thought the Council should wait to see the result of the first recommendation before going further. They should not put themselves into a violently antagonistic position with regard to the Society of Apothecaries. He hoped when the Society received the additional suggestion from the Council relative to the discontinuance of this examination that they would carefully consider it while reserving their legal position. There were times when important public bodies had got other things to consider than mere legal position. There was, as it were, a certain general sentiment that had to be taken into consideration by all public bodies, and there could be no doubt that the general sentiment of this Council was that those preliminary examinations in Arts should be conducted by bodies whose business it was to conduct examinations in Arts. He felt strongly that they ought not to take up a militant attitude to the Society. Let them go to the Society as friends, giving them friendly advice and suggestion, not brandishing a tomahawk.

Dr. BATTY TUBE could not agree with Sir William Turner.

It was not the Council but the Society of Apothecaries who was brandishing the tomahawk.

Sir W. FORSTER said he would vote against the motion in the hope of getting something stronger and better done at another meeting of the Council.

Dr. McVAIL expressed the view that it would be time enough to settle this matter when they knew what the Society had determined to do.

Dr. HERON WATSON said the recommendation was nothing but a covert threat, and urged the Education Committee to withdraw it—meantime at all events.

Sir JOHN SIMON said there was nothing to prevent the Council omitting the name of the Apothecaries' Society from the list of bodies they recognised. He was not at this moment prepared to recommend that course. It was their last resort. They could not go on recommending for ever.

Sir W. TURNER moved, "That the Council defer the consideration of Recommendations 2, 3 and 4 until the May meeting, so as to give time to the Society of Apothecaries to reply to Recommendation 1."

Dr. LEECH seconded this amendment.

Mr. BRUDENELL CARTER said he had no doubt that in May next he should be able to speak here with the authority of the Society. As to the proposed omission from the list of examinations, his own feeling would very strongly be that the only way in which it would be open to the Council to do that would be in the way prescribed by the Medical Act—namely, by representing to the Privy Council that the examination was inadequate.

The amendment of Sir William Turner, applied only to recommendation No. 2, was put to the Council and agreed to.

Dr. BATTY TURK then moved the third recommendation of the Education Committee. The committee, he said, were anxious to ascertain how far this registration was obligatory or not. As a preliminary measure they wanted to see whether registration was carried out by the bodies as a whole, and, having obtained information, they should be able to act.

Dr. BRUCE seconded the motion.

Dr. MAC ALISTER said that at Cambridge, although every student, he believed, was registered, the University did not require registration as a preliminary to admission to the professional examination. A larger number of students were, he believed, registered from Cambridge than any other school in England; but there was no duty laid on their registrar to see that they were registered. It seemed to him to be an office matter, and not one for the bodies, in the first instance, merely to see that the time which had elapsed from the appearance of the student on the Students' Register to the time of the diploma should be five years at least.

Sir W. TURNER said the argument of Dr. Mac Alister seemed to him rather to point to this—that the University of Cambridge wished to impose upon the registrars of the Medical Council duties which it should discharge itself. He would suggest to the University of Cambridge a very simple mode of discharging its duty—namely, that it should not admit to the professional examination any student who was not on the register. That was carried out in the University of Edinburgh; no student was allowed to appear for the professional examination unless he produced his registration certificate which he had got from the registrar in London or Dublin, or in Edinburgh. It seemed to him that the duty of seeing that students had been on the Register during the period that the Medical Council required was a duty primarily to be discharged by the medical authorities. He thought that was the proper way to look at it. He confessed that when he read the recommendation the thought occurred to him, how many additional clerks would be required in the registrar's office? Because, if they were to inquire into the diploma which was presented for registration at this office in London or the equivalent offices elsewhere, there must be a considerable amount of time spent in going through all the volumes of the Students' Register, to which Professor MacAlister referred. There were many students who went on the Register before the five years, and that search would not require to be made if the medical authorities themselves demanded the production of the medical students' registration certificate before they admitted them to the professional examination.

Dr. BATTY TURK stated that it would be found in the records that it was distinctly intimated by the Medical Council to the licensing bodies that the Council had no authority over these bodies as to the registration of students.

Sir W. TURNER said the licensing bodies should see that the student had been on the Register a certain length of time.

Mr. MACNAMARA said that with them in Dublin the first thing was to see that the student had paid his fee, the next was the registration certificate, and then they went through all the other certificates which might be required to entitle him to present himself for examination. The duty was discharged entirely by a committee of the joint boards.

The recommendation was adopted by 16 votes to 9, and the fourth recommendation was withdrawn.

#### Reports by Committees.

On the motion of Dr. BRUCE, seconded by Mr. BRUDENELL CARTER, it was decided without discussion that "each committee shall once a year, at least, make a report on the subject referred to them by the Council."

#### Application for Registration.

The next business was the consideration of the application for registration in the Medical Register, referred to the General Council by direction of the English Branch Council, from Mr. Freeland John Freeland, L.S.A. Lond. 1884, M.R.C.S. Eng. 1885, L.R.C.P. Lond. 1886, who has resided in Antigua since obtaining his qualifications.

The REGISTRAR stated that the English Branch Council, whose function it was to do so, had investigated the statements made by Mr. Freeland and had found them to be correct, and now recommended the General Council to direct the registration of Mr. Freeland.

The recommendation was agreed to.

#### Fee for Antedating.

Sir DYCE DUCKWORTH moved the following recommendation of the Students' Registration Committee, "That with regard to all future applications that may be made for the antedating of the commencement of professional study by medical or dental students, no such application should be granted except subject to the condition of the payment of a fee of half a crown to the Branch Council through which the application may be received." There was, he stated, very little to be said on this point. Antedating gave rise to a good deal of trouble, especially in the office, and it was thought the payment of a small fee would prove useful in several ways. In the first place, when it became known that there was a small fee attached to it, it would make people a little more punctilious and careful. The amount of correspondence and work required in the office was so much more in these cases than others that it was thought desirable to charge a very small fee in each case. That commended itself to all the members of the committee and he thought the Council would see the force of it.

Dr. BRUCE seconded the motion.

Sir W. TURNER: That is a sort of fine, if I understand it.

The PRESIDENT: Yes.

The recommendation was agreed to.

Dr. MOORE moved the following recommendation from the same committee on the same subject, "That, with a view to terminate the undesirable practice of antedating, the attention of the authorities of all the medical schools in the United Kingdom be called to the extreme importance of not allowing students to commence a professional course of study before they have passed their preliminary examination—the subjects of which, according to the regulations of the Council, must be all taken at one and the same time—and of seeing that their registration is then immediately effected." If the registration of students was desirable, he observed, it was quite clear that it should be carried out as systematically as possible.

Sir DYCE DUCKWORTH seconded the motion, which was agreed to.

This concluded the business of the session and the Council then rose.

THE NEW EYE HOSPITAL, SOUTHWARK.—This institution, which is to be opened on the 15th inst. by the Duke of York, marks a special feature in hospital construction. It is, probably, the only hospital in the kingdom which is absolutely fire proof. The floors are made of iron and concrete, and the whole of the fittings are of teakwood, which is said to be non-inflammable. Ample provision is made in the event of an outbreak of fire. The building is entirely warmed by hot water and lighted by electricity. There is not in the building a single angle or projecting ledge which could harbour dust or injure a blind or semi-blind patient.

## REPORT ON THE SANITARY MEASURES IN INDIA IN 1890-91.

THIS report, which has just been published, is one which is compiled for presentation to both Houses of Parliament, and it deals with the vital statistics and medical history of India as a whole and with the causes and progress of epidemic and other important kinds of sickness that have prevailed during the year, together with the sanitary measures that have been introduced. It is, in reality, a condensation of all the annual reports furnished by the sanitary and medical officials to the Indian Government, to which is added, as an appendix, the various memoranda drawn up by the Army Sanitary Commission in this country for the information of the India Office. The whole forms a Blue-book of 226 pages of the most analytical and condensed kind of composition, and forms an excellent sample of what is termed in official life "precis writing," which, it need scarcely be said, is not a form of light literature. These reports, nevertheless, contain a large amount of varied information, some of which is of an original, and much of it of an interesting and instructive character.

We considered some months ago the report of the Sanitary Commissioner with the Government of India, and especially those portions of it which dealt with the European army in that country, consequently there is no need to dwell upon that subject now. We may remark, however, that the loss to the whole army by invaliding in 1889 was equal to 25·29 per 1000, and that the proportion of invalids to strength was least in Madras and highest in Bombay. Of the total number invalided 35 per cent. were discharged as unfit for further service. In the European army as a whole 78 per cent. of the total strength had seen less than five years' service. As regards the native army the mortality from pneumonia was more than four times as great as that of the European soldiers. On the other hand, the death-rate from enteric fever was only 0·7 per 1000 among the native troops, as compared with 4·91 among European troops and 0·09 among prisoners in gaols. Dr. Gregg, the sanitary commissioner for Bengal, speaking of the great prevalence of malarious fevers among the native population, remarks that the more personal knowledge he gains of Bengal the more does he feel convinced that the want of free drainage is one of the principal causes of the excessive unhealthiness of the province. Most people would be disposed to concur with him in this opinion. Theoretically it is easy enough to indicate the remedy, but its application practically would be a very difficult matter owing to the enormous expense that would be involved by the introduction of any adequate system of drainage.

Turning to the appendix, which contains the memoranda furnished by the Army Sanitary Commission, we come to some comments and remarks which are of more than ordinary interest at the present time, when the presence of cholera in Europe is exciting so much attention. That disease was but little prevalent among the troops in India in 1890. Of the 58 cases of European soldiers treated, these were spread over eighteen stations and over nine months of the year. Except at Lucknow, where there were 18 cases, the attacks at any one place were few and in many instances confined to one or two cases. The same remarks apply to the history of the disease among the native troops. The localisation of cholera is well illustrated by the proportion of buildings attacked out of the total number occupied. For British troops this proportion was 15 per cent., for native troops 3·18 per cent. and for gaols 24·6 per cent. The results of moving into camp continued to be very satisfactory. The effect of season on the prevalence of the disease, and the synchronous rise and fall in the number of attacks and fatality, as if in obedience to some general influence operating in common, in outbreaks at different places, often widely separated from one another, were also well-marked phenomena.

The Army Sanitary Commission makes some important remarks of a practical kind as the result of their critical analyses of different reports, and to some of these we may now advert. As regards the striking difference between a non-epidemic and an epidemic year, let us take by way of illustration an interesting and graphic diagram of the monthly rise and fall of cholera in the Punjab during each of the twenty-four years from 1867 to 1890. In 1866 only 12 deaths were registered throughout the whole province. In 1867 the number was 43,146. No figures could enforce more

clearly the contrast between a year when cholera was practically almost absent and one in which it was epidemic. Similar though not such marked, contrasts may be observed between other years. It is commonly most severe in the province in the months of July, August and September; but, as so often happens, its prevalence in these later months of the year is heralded by isolated attacks much earlier—in April, for example.

As regards the relation of cholera to railways, the Sanitary Commissioner for the Punjab states that many railways have now been opened in the province, affording rapid means of communication between distant places, and the disease is doubtless rapidly distributed by that means. The Army Sanitary Commission, on the other hand, oppose this view, because they do not consider it to be borne out by the facts. They say that they have examined the report "in order, if possible, to find any facts tending to show that the epidemic of 1890 in the Punjab was affected by the railways, but we can discover no facts of this kind. On the contrary, the whole history of the epidemic would seem to prove that the railways had no influence whatever in this respect. In order to see this clearly, it is only necessary to look at the cholera map. Beginning with the south-east, we have cholera beginning in the Delhi district on April 25th. The next important place on the line going north-west is Umballa, and here it did not appear till June 2nd. Next Ludhiana, June 21st, or south to Goorgaon on May 12th. All these places are within not many hours' distance by rail from one another. Many other examples might be cited; but we need only add, generally, that there is no instance of rapid spread such as requires the introduction of the railways to explain. In connexion with the railways, indeed, the most remarkable fact is the exemption of large areas through which trains from affected districts were daily coming. This is to be seen in the large tracts traversed by the line from Lahore to Peshawar in the north-west and from Lahore to Mooltan in the south-west. Both these tracts of country suffered very slightly; in many of the districts comprised in them there was no cholera at all. On the other hand, districts removed from railways suffered to a considerable extent. If it could be shown that the railways are the great disseminators of disease they would certainly be far from an unmixed blessing to the people; but there is no evidence of the kind. The problem to be solved is, whether the improved means of communication have rendered epidemics of cholera in India more rapid and widespread than they used to be, and the facts, so far as we are acquainted with them, entirely negative any such supposition."

As regards the question of importation and land quarantine, the Army Sanitary Commission say in another place that unless the whole commerce and social life of a province is to be brought to a standstill, it is not possible to control the movement of the people from one village to another or from one district to another. Any attempt of the kind would involve an army of police with an enormous expenditure; it would be regarded by the people as a grievous interference of an oppressive nature with their trade, occupations and social intercourse. Whatever scientific interest may attach to the theory of importation as the cause of cholera, this question, especially in a country like India, is, in the opinion of the Army Sanitary Commission, altogether outside the pale of practical sanitary action. They hold apparently that the only reliable means of dealing with cholera and other diseases is to improve the sanitary conditions under which people live, one of the most important of which is the water-supply, for there is no safety, they remark, against virulent epidemics where there is an unprotected water-supply. As to the liability of pilgrims to be attacked by cholera, this is a well-known fact that has been frequently insisted upon, but the evidence regarding the dissemination of the disease by them is still considered very imperfect; and the Army Sanitary Commission lay down different points that require to be carefully investigated and set forth before such evidence can be deemed of a sufficiently complete and satisfactory character. They urge that in India, and more especially in Bengal proper, where hundreds of cases of cholera are constantly occurring over a vast area, it is impossible to prevent persons—be they pilgrims or not—passing from one village in which there are one or more cases of cholera to another which is free from the disease. The only practical measures for the prevention of cholera are sanitary improvements—improvements in drainage, water-supply, dwellings and the other requisites of health.

## CHOLERA.

### CURRENT NOTES, COMMENTS AND CRITICISM.

THE appearance of cold weather on the Continent—for in this country it has been remarkably mild up to the present time—has had a markedly repressing effect on the epidemic, which may be said to have almost disappeared, although it still lingers in various places. Last week sixteen deaths occurred from cholera in Holland, and since then three fatal cases are reported from Gastel, in North Brabant, and one fatal case at Weesp, in North Holland. At Budapest the fresh cases now average two or three, with one death, daily. There have been several fresh cases of cholera, with two or three deaths at Dunkirk and in the surrounding villages. The *Débats* publishes a telegram from Cherbourg of Nov. 29th announcing the presence of the disease at that place and some of the neighbouring villages, and of two fatal cases at Gonnevill.

Professors von Pettenkofer and Emmerich's experiments have of course afforded materials for comment and discussion. In the case of Professor Emmerich it is understood that after his experiment of swallowing the comma bacilli he purposely indulged in some errors of diet—that is to say, he partook of a variety of things at supper which were calculated to disagree with most people. It is perhaps noteworthy that some diarrhoea followed the experimental swallowing of the bacilli in both cases, and still more noteworthy that bacteriological examination of the dejecta showed that a very large increase in the number of these bacilli had taken place. But the negative phenomena that followed the experiments, although they have a certain value, do not of course prove that because cholera did not result in these experimenters it would not do so in other and more susceptible persons. All estimates, however, which have been put forward as to the number of persons who may be regarded as cholera proof are purely conjectural and of no scientific value. Outside Germany the doctrine that the comma bacillus is the cause of cholera is not by any means universally received. Its presence is still regarded by many authorities as a concomitant feature in the morbid process and the index of a condition brought about by physico-chemical changes in the tissues rather than as the cause of that condition. We do not yet know sufficient about the life history of the comma bacillus, its morphological varieties and their pathogenic and other relations to one another, the exact time at which these micro-organisms manifest themselves in cholera, and the part which diseased tissues and fluids play in providing the necessary soil and nidus for their development and breeding, or the nature of the changes which these vitalised agents bring about and the virus which their presence is assumed to produce, to warrant us in dogmatising, as if our knowledge were of an assured and demonstrable kind. We are still sadly in need of more light being thrown on these and other matters before we can turn them to any practical account, and we must await the publication of the observations which have been made by various continental observers during the present epidemic before we are in a position to say what advances have been made in our knowledge of the etiology and pathology of cholera.

### THE CHOLERA IN FRANCE.

(FROM OUR SPECIAL CORRESPONDENT.)

#### A VISIT TO TROUVILLE.

*Tardy and Exaggerated Precautions.—Effects of Fear.—Coercive Measures against Well Water.—Houses without Drains.—Rival Drainage Schemes.*

TROUVILLE is probably the most fashionable watering-place in the north of France. It has been regarded as the summer boulevard of Paris and is certainly the rendezvous of the gayest, the most fashionable and extravagant sections of Parisian society, yet Trouville is but a very small town, possessing barely 7000 regular inhabitants. It is situated at the mouth of a small river called the Tonques and not long ago was little better than a mere fishing village. There is,

however, an unequalled beach of soft sand, and gentle slopes facing the sea offer excellent sites for the erection of villas and mansions. Hero beautiful dwellings have been constructed, together with a luxurious casino. To the north-west of the beach is the English Channel, and to the north-east, across the broad estuary of the Seine, can be seen the town of Havre. Steamers ply backwards and forwards from Havre two and three times a day and the inhabitants of Havre often come over to Trouville for a sea bath and a few hours' recreation. Though these casual visitors add to the wealth and gaiety of the town in normal seasons, they were far from welcome when the cholera was raging at Havre. When the Trouville and Deauville races are run as many, it is said, as 10,000 persons have been brought over by the Havre boats in one day. The greater part return to Havre the same evening.

On Aug. 13th, 14th and 15th last a great international concourse of firemen gathered at Havre. Dr. Gibert, as medical officer for epidemics, protested and urged that this fête should be postponed, for there had been deaths from cholera at Havre ever since July 15th. This advice was not followed, and among other visitors the Fire Brigade of Trouville went over to Havre. On their return eight of the company were seized with violent diarrhoea and cramps. Fortunately all the firemen recovered and as cholera was not yet suspected no particular precautions were taken. It would be interesting to know whether any of the English firemen who went over in considerable numbers to Havre for these fêtes suffered in a like manner on their return to England. Also, it is most important to investigate the character of the violent diarrhoea often contracted by persons who are in towns where cholera prevails. Is such diarrhoea a sort of abortive cholera capable of producing true cholera by contagion among other more susceptible subjects? If so, some of these firemen who simultaneously fell ill after spending a few days at Havre may have brought the germs of cholera to Trouville. But others were ill besides the firemen, and so far back as the previous month of April some of the numerous visitors coming from Paris might have brought cholera to Trouville. I have already related that at Havre the first case of cholera occurred on July 5th and the patient was a woman who had just arrived from Paris. As Trouville is essentially a Parisian resort, a very large proportion of its summer visitors came from the infected capital. For several weeks after cholera had broken out at Havre visitors in thousands came over to Trouville from that town, while the Trouville Fire Brigade and many others went over to Havre. As a result there were not only suspicious cases of illness, but four deaths from cholera at Trouville; and close by, on the other side of the narrow river at Deauville, seven deaths from the same cause. In a word, Trouville was exposed to cholera infection without let or hindrance for four clear months. Will it be credited that, after having passed through this danger scathless, it then occurred to the authorities that it was necessary to take precautions? This inconsistency may, however, be explained on financial grounds. Towards the end of August there were some 4000 visitors still remaining at Havre. This represented receipts for the trade of the town of about £2000 per day. By this time the prevalence of cholera at Havre had become notorious. People believed more readily in the Havre cholera than they did in the Parisian cholera. No one suggested that intercourse with Paris should be stopped, even though Paris had infected Havre, but the visitors at Trouville threatened to go away if the steamships plying between Havre and Trouville were not immediately stopped. Under these circumstances the municipality gave orders that no vessel from Havre should be admitted into the port of Trouville. Of course the goods usually sent from Havre reached Trouville just the same, though, as they were sent by rail, they came by a circuitous route. So also with regard to passengers; only there was this important difference, that passengers landing from the boat obviously came from Havre and could, in consequence, be watched. On the other hand, travellers by train need not book through, and there was nothing to prove they came from Havre any more than from any other part of the country. In spite of these facts the steamboat traffic was interrupted for ten days, nor would it have been re-established at the end of this time but for the active intervention of the Minister of the Interior. When the communications were thus re-established extraordinary precautions were imposed. To pacify the alarm of the inhabitants a disinfecting stove was sent to Trouville by the Minister of the Interior. This feeling of alarm was

graphically illustrated by the experience of one of the local chemists. Before the steambot service with Havre was suppressed he sold about fifteen preparations of bismuth per day, but as soon as the boats ceased running he only sold two or three such anti-diarrhoea mixtures in the course of a day. An amusing anecdote is told of the chemist at the neighbouring small bathing station of Villerville. The season was at its height, everyone in excellent health, when, on a certain day, the walls of the little town were covered by official posters bearing the signature of the prefect of the department, and describing what precautions and sanitary measures should be adopted to prevent the advent of cholera. On the very next day the local chemist had to make up forty-five prescriptions for colic. Yet, as none of these cases developed into cholera, it is clear that they were simply the result of the alarm caused by the official poster. So to pacify such fears minute precautions were taken when the steambot service was re-established. Every passenger had to submit his luggage to very careful examination. All soiled linen was seized and disinfected in the stove lent by the Minister of the Interior. Then all persons who came from Havre were watched for five days. The hotel keepers were supplied with disinfectants and elaborate explanations were given, so that they might know what to do while waiting for the arrival of the doctor. When cases of diarrhoea occurred everything that was at all likely to be soiled was at once burnt. It is thought that these precautions saved the town of Trouville; but as they were taken so late it seems to me more likely that the town was not in a condition favourable to the spread of cholera. This does not, however, imply that Trouville can boast of good sanitation. No such assertion can be made, though certainly the death-rate is not so high as that of Caen. The deaths from 1882 to 1891 were annually 143, 155, 138, 155, 175, 151, 153, 175, 159, 172. This gives an annual average for the ten years of 157.6 deaths. The population of Trouville is now estimated at 6700; the previous census gave the number as 6308; so that the average may be taken as 6500 for the ten years, or a death-rate slightly exceeding 24 per 1000 per annum. But considering that there are sometimes as many as 30,000 visitors at Trouville, in the statistics of the town budget the average population is put down at 10,000. This figure is reached by the calculation that if twelve different visitors each remain one month at Trouville, this counts as one person for one year. If such a system of counting is to be admitted, then the death-rate would only be equal to 15.7 per 1000, and certainly the death-rate of so luxurious and wealthy a place as Trouville ought not to exceed the latter figure. But however these statistics may be twisted about, there is good reason to believe that the death-rate could be considerably reduced, and this simply because the sanitary condition of the town is far from satisfactory.

Fortunately the municipal authorities at Trouville are thoroughly awake to the importance of good sanitation. They have already submitted to the Government a general scheme of drainage and, pending its realisation, have adopted some useful measures. It must also at once be stated that Trouville has a water-supply, not of its own, but farmed out to a private company. The water comes from a distance of seven and a half miles, and is brought to the town in conduits that are made partly of iron and partly of cement; these works were terminated in 1878, but I believe some portions of the canal require repair. The water is stated to be pure but hard, and is sold by the company to the inhabitants of the town at the rate of 5*z.* per cubic metre in winter and 10*z.* in summer. Formerly there were wells, and when a purer supply of water was brought to the town many people still continued drinking the well water. But some time ago a celebrated actress died of typhoid fever which, it was said, she had contracted at Trouville. This supplied the pretext for a violent campaign, started in several newspapers, against Trouville. These denunciations have done a great deal of good, and have achieved more for the education of the people and authorities at Trouville in sanitary matters than any number of learned lectures or scientific demonstrations. First and foremost the mayor caused all public fountains which derived their water from wells to be closed. Then he convoked all the hotel- and lodging-house keepers and explained to them how disastrous it would be for the town if another case of typhoid fever occurred among the visitors. To avoid such a calamity they must cease drinking water from private wells and subscribe to the water company's supply. On the proprietors of cafés the authorities were able to bring to bear

more direct pressure. Those who refused to subscribe to the town water-supply were specially watched by the police and, at the very first and most trivial infraction of the licensing laws, were at once prosecuted. They soon found it paid better to subscribe to the town water-supply. This shows how defective are the sanitary laws of France. There should be no necessity to resort to indirect coercion to prevent the use of sewage-contaminated well water in cafés. It is true that fifteen years ago a municipal decree was issued declaring that all cesspools in Trouville should be rendered watertight. The water of the neighbouring wells ought not, therefore, to be contaminated; but we all know how illusory are such decrees.

In a project for the drainage of Trouville, presented by the mayor, M. Durand-Conyère, and adopted by the Municipal Council on April 4th of this year, it is stated that there are 150 houses in the town with watertight cesspools and 650 houses with cesspools that are not watertight. Further, there are 650 houses which have *tinettes* or pails and no less than 320 houses that have no closets whatsoever. Where the cesspool is really watertight the inhabitants use as little water as possible, so that they may avoid the expense of frequently emptying the cesspool and ensure a high percentage of fertilising ingredients in its contents. Under these circumstances it cannot be expected that soil pipes should be trapped, for that requires too much water. It is estimated that the emptying of cesspools costs 8*s.* per head per annum. The police insist that all new houses shall have watertight cesspools, therefore it is not practical to put up a proper water-closet with a two-gallon flush in a new house. Where the cesspools are not watertight they, for the most part, infect the surrounding subsoil. A few cesspools, however, notably in the centre of the town, in the Rue des Bains, the Rue de la Mer, and the Rue Pellerin, have overflow pipes into the sewers. As the cesspools must be full before they overflow, the matter that reaches the sewers is very foul indeed and occasions serious nuisance. Many of the *tinettes* or pails are made of wood and have no lids. They sometimes remain two and even three months in a house before they are removed and empty ones put in their place. Of course fermentation sets in and the consequences are dangerous and intolerable. As regards the 320 houses that have no closets at all, at about 10 p.m. the occupants of these houses may be seen emptying their utensils into the stream of the *fonques*, and, near the railway bridge especially, the nuisance this causes is very perceptible.

The slop water of all the houses is allowed to drain into the street gutters, and from the gutters gradually finds its way to the few sewers that exist in the town. These sewers, however, have insufficient fall; therefore heavy deposits are made in the sewers, the water flows very slowly, and when the tide is high the sea-water enters the mouth of the sewers and further checks the flow. Some houses, instead of draining into the gutter, which has at least the advantage of disconnecting the house from the sewer, are directly connected with the sewer, and the precaution has not been taken of trapping the pipes. Such houses, therefore, act as sewer ventilators and draw off the foul sewer air into the kitchens and dwelling rooms. These glaring defects are not, however, special to Trouville. They will be found in almost every part of France. What is special to Trouville and greatly to the honour of its administration is the fact that these evils are recognised and publicly denounced by the administration itself.

The municipality of Trouville has had under consideration three different schemes for the draining of the town. The first is the "*tout à l'égout*" or the English water-carriage system; but, in consequence of the bathing on the beach, there is no convenient outfall, and there is not a sufficient water-supply to flush the drains and sewers. It is estimated that the cost of building sewers, of increasing the water-supply and of management would amount to £36,400, and the cost of building water-closets, drains &c. in the houses would amount to £79,600, making a total of £116,000. The second scheme is the Berlier system of pneumatic drainage. This is estimated to cost £56,272, or, according to a more recent project, augmenting considerably the length of the streets so as to reach the total of 22,000 metres, including ground that may in future be built upon, the estimate is £64,000. The objection to the Berlier system rests on the assumption that the evacuator under each house would cause a nuisance if the house were not inhabited. Where there is a large house and the evacuator is constantly filled and constantly emptied no complaint

arises; but in Trouville many of the houses are small and many are uninhabited for six months or more. It does not seem to me that there would be any great difficulty in flushing these evacuators at the end of each season. However, the municipality has given its preference to a project of pneumatic drainage which is more like the Liernur than the Berlier system. This is known in France as the *système aspirateur*, and a company, the Société Générale d'Assainissement, proposes to apply this system to the town of Trouville on terms which the municipality considers the most favourable and the most practical. The cost of application would amount on an average to £4 10s. per house. Air-tight suction sewers, 22,000 metres in length, with engine-house and works for producing vacuum &c., are estimated to cost £17,200, and the sewage is to be drawn off to a guano factory some miles distant from the town.

It is not for me at the present moment to investigate the respective merits of these rival schemes. It suffices to say that the worst scheme would be infinitely preferable to a continuation of the present state of affairs. This much in passing I will, however, urge—namely, that the scheme which has found favour with the Trouville municipality, in common with the Liernur system as I have seen it working at Amsterdam, does not ensure, but, on the contrary, hinders, the maintenance of the perfect cleanliness of the soil pipes within the houses. In the Liernur system and its French adaptation the soil pipe retains the soil till such time as a functionary draws it off by bringing to bear the pneumatic suction. But, however this may be, it is gratifying to find that the municipality of Trouville is stirring in the matter, and is determined that, in one way or another, its town shall be properly drained.

## THE BRAIN OF THE LATE MR. GEORGE GROTE, F.R.S.

### II

IN THE LANCET of Nov. 12th we referred to many interesting peculiarities in the brain of Mr. Grote, as reported on in the *Journal of Anatomy and Physiology* by the late Professor John Marshall, and we now add some further details as to this particular brain together with some suggestions on cerebral physiology by the same anatomist. The general form of the brain must depend greatly on the shape of the skull, and must to a great degree correspond with it. The extreme length of Mr. Grote's head still covered by the soft parts was 8.1 in., its extreme breadth 6.5 in.—a ratio of 100 to 81—and its circumference 22½ in. Such a skull would be included among the brachycephalic, although it is just on the border-line; but a measurement of 15½ in. from one auditory meatus to the other over the vertex shows that its height was the great characteristic, for this is quite half an inch above the average of an English skull with the same circumference. This peculiarity opens up the question whether an unusual height of the cranium is necessarily or usually associated with a relatively large cerebrum or a small cerebellum, or it is only correlated with a diminished size of the lower occipital fossæ of the skull? In long skulls (dolichocephalism) the intermastoid measurements are generally low, whilst in broad skulls (brachycephalism) they are high. But although in Mr. Grote's case the unusually high measurements over the vertex were associated with a large cerebrum and a relatively small cerebellum we have no data on which we can rely for a further pronouncement on such an interesting problem. The dimensions of the cranial fossæ occupied by the cerebellum must be much more fully mapped out on the skull and carefully taken and recorded before we can discuss this point, in view of national, racial and individual peculiarities, and particularly if such measurements are to be applied to the living subject.

Mr. Grote's brain, when removed from the skull, appeared broad in proportion to its length, and, whilst fully acknowledging the difficulty of defining and expressing the relative size and extent of the various lobes, Professor Marshall, from his naked-eye observations on other brains side by side with this one, came to the conclusion "that the frontal lobes of the cerebrum appeared to be very long on their upper surface, very wide in front of the Sylvian fissure, and both long and broad on their under surface; the parietal lobes were short and wide; the temporal lobes were also wide, though short; the occipital lobes were small and shallow." He has also

suggested a valuable method of ascertaining the weights of the several lobes and their white conducting fibres, and gives full directions for making these dissections. "On being weighed, the several lobes were found to be in very nearly their usual proportion—a chief individual distinction being that the fronto-parietal mass was somewhat heavier than usual, this superiority being mainly due to an excess in the parietal lobes; the temporal lobes, however, were a little smaller, and the occipital lobes decidedly smaller than usual. The cerebral convolutions were very massive, being not only broad and deep, but well-formed and marked with secondary sulci over the whole cerebrum, but especially in the frontal and parietal regions." This relative development of different lobes and convolutions is now being studied in the light of experimental and pathological research, and has afforded us much exactitude of knowledge on localisation of function, especially in regard to the motorial area of the brain. Professor Marshall held a critical and most judicial view as to the results to be deduced from these experimental inquiries, observing that no amount of mere argument can touch the facts, however difficult they may be to understand, but that any use which is to be made of them must be cautious, reserved, and even hypothetical. Applying this method, he asks the following questions, after critically examining Mr. Grote's cerebrum:—"Supposing that we assume size and complexity of convolutions to be evidence of superior functional capacity, might we credit the very large orbital and anterior frontal regions of Mr. Grote's cerebrum with the active and able exercise of proper mental processes, and the relatively small occipital lobe with a comparative deficiency of conduct, or carelessness as to personal interests and safety? May we associate the relatively large convolutions in the frontal and parietal regions, before and behind the fissure of Rolando, with the large upper and lower limbs of a person nearly six feet, even though the purposive movements of those limbs are held in but moderate equilibrium or control by a comparatively small cerebellum? How shall the great breadth, yet comparative simplicity, of the inferior frontal convolution be interpreted in reference to any peculiarities as to verbal expression or lingual utterance? Was the bold development of the back convolutions associated with any great activity of visual perception or the relatively full development of the superior temporal convolution with any special appreciation of a love of sounds?"

Other marked peculiarities of Mr. Grote's brain were the relatively large quantity of white fibres and the asymmetry of the cerebral convolutions. This asymmetry is remarkably well shown in three photographs which are reproduced at the end of the article. Asymmetry, suggested by Professor Marshall, could scarcely be correlated with the performance of higher intellectual processes, or with their more perfect performance, for it is difficult to detect any obvious advantage in purely intellectual operations, being, as it were, hampered by an asymmetrical apparatus. He refers it to the habit, common to and inherited by the human family, of using for special purposes the right hand more than the left, generation after generation, and to all the direct and indirect consequences arising therefrom throughout its organism. This chapter is to us the most interesting and suggestive in the article. In Mr. Grote's cerebrum it was apparent on transverse section that the broad and massive character of the convolutions was due to the relatively large amount of the white substance. The sectional area of the corpus callosum was  $\frac{3}{4}$ ths of a square inch, which is about six times the ordinary proportion when compared with the total area of the inner surface of the hemisphere. "It is obvious that so high a ratio of white commissural or radiating substance must have great significance as regards the more effectual utilisation of the grey matter itself. If the grey matter be the source or seat of all special actions, whether original or reflex, exercised by or within the cerebral hemispheres, the white fibres must be accredited with the offices, not only of bringing impressions from the confines of the human frame, and conveying impulses to its muscular apparatus, but likewise of utilising to the utmost the power of the grey matter by multiplied connexions of part with part, in countless lines of combination and reflection. Just as the usefulness of the apparatus employed in telegraphy is increased according to the number of its adjuvant and event wires, so the efficacy of a certain quantity of grey matter, containing a certain number of ganglionic corpuscles, is enhanced by the multiplicity and variety of the connexions and combinations of these latter. Whether for old or for recent impressions, the paths of intercourse, combination, contrast,

construction and volitional impulse would all be increased, and the efficiency of the cerebral apparatus be thus improved. Certain it is that, under normal conditions, a well-developed corpus callosum must add to the possible, if not to the actual, capacity for work of a bilateral cerebrum; and, although cases of its absence, unsuspected during life, are on record which require further investigation, yet its relative magnitude is undoubtedly associated with varieties in intelligence or training."

### THE METROPOLITAN HOSPITAL SUNDAY FUND.

ON Friday, Nov. 25th, a meeting of the Council of this Fund, presided over by the Lord Mayor, was held at the Mansion House, for the purpose of considering the draft report of the Council, which stated that the twentieth year of collecting the fund had resulted, under the presidency of the Right Hon. Sir David Evans, in a total of £41,512, and that a further anonymous donation of £500—£250 to be used in providing surgical appliances and £250 in aid of the general fund—had been received. One legacy only, £105, had been received during the past year, and a donation of £1000 had again been most generously given by Sir Savile Crossley. The report was passed and the next annual meeting fixed for Tuesday, Dec. 13th.

Mr. Culance, the secretary of the Fund, intimated that the leading clergymen had been consulted, and it had been suggested that June 11th should be fixed for the hospital collection. Archbishop Vaughan had consented to put off the annual school collection in the Catholic Church, which happened to fall upon June 11th next year, to the 18th or the 25th of the same month. It was finally recommended that June 11th, 1893, should be adopted as the date on which the collection of the Fund should take place. The Rev. Dr. Marks proposed and the Rev. Dr. J. Kennedy seconded the following resolution, which was unanimously passed: "That it be recommended to the Committee of Distribution that all accounts presented under Law 4 of the Constitution on or from Jan. 1st, 1893, shall be audited by a chartered accountant."

A vote of thanks to the President concluded the meeting.

### THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of the Association of Fellows of the Royal College of Surgeons of England was held at 5.30 P.M. on Wednesday, November 30th. Mr. George Pollock, the President, occupied the chair. The minutes of the last meeting were read and confirmed. The hon. secretary read the reply which had been received from an official of the College in answer to the last communication which had been forwarded to him by the committee. This reply was considered by the committee to be of a very unsatisfactory character, inasmuch as the writer neither attempted to substantiate the allegations which had been categorically refuted by the committee, nor withdrew them. A long discussion then took place with reference to the course of action which should be pursued. In the first place, a letter was drafted expressing the regret of the committee that the inability or unwillingness of the gentleman in question to substantiate his repeated allegations had not led him frankly to withdraw them, and stating what course of action the committee would pursue. This letter was unanimously adopted, and the hon. secretary was directed to forward a copy of it to the gentleman concerned. In the second place, it was agreed that, in the event of no satisfactory reply to this communication being received within fourteen days, the hon. secretary should proceed at once with the publication of the whole correspondence, with a view to submitting it in the form of a pamphlet to the Fellows of the College.

A letter was read from the hon. secretary of the Members' Association asking to be favoured with a printed list of the names of the members of the Fellows' Association, as well

as with a copy of their last report. The latter request was made with the view to the publication of a report of the proceedings of the Association of Members. The hon. secretary was directed to forward the "Further Account of the Proceedings of the Association of Fellows," published in June last, and to say that a printed list of the members of the Fellows' Association had not yet been issued.

This concluded the business of the meeting, and the committee adjourned.

### DEATH FROM ELECTRICITY.

By H. A. CLOWES, M.D., M.S. DURH. &c.

DEATHS from electricity have happily been of rare occurrence in this country. So far as I am aware, only five cases have been reported in the medical journals since 1880, though many cases have occurred in America and several on the Continent.

On the afternoon of Nov. 9th T. P. L.—, aged twenty-three, an employé of the House-to-house Electric Supply Company, was engaged in making connexion with a house in Roland-gardens, Old Brompton-road, and while working in the surface box he was observed to fall to one side as if in a fit. A fellow-workman ran to him, and found him with his left arm contracted and attached by his left hand to the connecting wire. The wire was immediately broken by a blow with an axe handle, and when released he gave a loud sigh and fell forwards on to his forehead, but made no further movement or sound. He was brought in a cab to the Queen's Jubilee Hospital, where I saw him about five minutes after the occurrence. The heart and respiration had then stopped. The face, neck and upper extremities were congested, the eyes suffused and the pupils widely dilated. The features were not distorted and the face wore a peaceful expression. There was a strong smell of burning not unlike the smell of gas, and it was at first reported that the man had fallen down while working on a gas main. The palm and first two fingers of the left hand were burnt and charred and the fingers were strongly flexed. The clothing was not burnt or injured in any way. Artificial respiration was at once commenced, and was maintained for more than an hour, but the patient did not respond in any way, and it was evident that the case was hopeless. Besides artificial respiration an injection of strychnia was given, with the idea of stimulating the respiratory centre, and the faradaic current was applied to the precordia.

At the inquest, which was held on Nov. 14th, the current which the man received was said to have been a rapidly alternating one (10,000 alternations per minute) of a strength of about 2000 volts. It was not clearly shown how he had completed the circuit, for at the time of the accident he was holding only one wire with the left hand, which was burnt, but there was no other burn on any part of the body. The piece of wire which he held had in some way become denuded of the insulating rubber. A post-mortem examination was made three days and sixteen hours after death. The body was that of a well-developed, muscular young man, and the congestion of the face, neck and upper extremities and ocular conjunctiva remarked at the time of death was still noticeable. Rigor mortis, which had set in shortly after death and had been strongly marked, was still present to a slight extent in the lower extremities. Decomposition was not advanced in any unusual degree. The whole of the palmar surface of the forefinger and middle finger of the left hand was burnt and the tissues of the carpal half of these two fingers were destroyed and carbonised, exposing the flexor tendons. The epidermis generally of the palm of the hand, the palmar surface of the thumb, and of the cleft between the thumb and index finger was burnt black and separated from the deeper structures of the skin. On the dorsal surface of the hand, between the thumb and index finger, the epidermis was destroyed and missing over a surface the size of a florin. There was a small circular abrasion, not a burn, on the outer side of the right knee, and a small ecchymosis and swelling over the right frontal eminence. There were no other external marks of injury. The vessels of the scalp, meninges of the brain and brain substance were congested and full of liquid blood, and the surface of the white substances when cut across presented a punctate appearance. The lateral sinuses were full of liquid blood, and the lateral ventricles contained a fair amount of cerebro-spinal fluid.

The brain and cerebellum appeared quite healthy. The mucous surface of the larynx, trachea and bronchi was much congested and the lungs loaded with dark blood. The heart was normal in size and consistence and its valves healthy. Although not contracted its cavities were completely empty and there was a deficiency of blood in the large vessels. The liver was much congested and of a dark-red colour. The spleen was large and engorged with blood. The kidneys were large (especially the left), congested and the condition of the tissues doubtful; the stomach and intestines were normal in appearance; the bladder contained about eight ounces of highly albuminous urine. A marked feature of the examination was the complete fluidity and dark colour of the blood, not a clot being discovered in any part of the body. My colleague, Dr. Thudichum, who kindly made a microscopic examination of the blood and nerve tissues, supplies the following note: "Blood quite fluid, without any coagula, and remains fluid on being kept; medulla oblongata and amido-myelin coagulated; no other structural change." He adds: "Electrical current derived from wire to earth 10,000 alternations per minute, causing 20,000 shocks of contraction per minute, practically tetanus."

Walterton-road, W.

## THE ROYAL SOCIETY.

THE Royal Society has on many occasions recognised the scientific work of medical men, and among the names which it delights to honour are not a few that are associated with those sciences which have been cultivated chiefly for the purposes of the art of healing. Last Wednesday's dinner, and the formal presentation of medals which accompanied it, has made an addition to the number of such names which are inscribed upon the medal roll of the Society. Foremost among them the recipient of the Copley medal, which has been termed "the laurel wreath of the Royal Society," was the venerable Virchow of Berlin, whose name—although connected by the terms of the award as well with prehistoric archæology as with pathology and pathological anatomy, and by Professor Huxley in his very interesting speech with the even remoter field of politics—is of European reputation because of its bearer's brilliant discoveries in pathological science. Mr. Langley, of Cambridge, the recipient of the second royal medal, is a brilliant representative of the younger ranks of the medical profession. On this occasion he acquitted himself in the difficult office of replying to the toast in honour of the medallists, in behalf of his absent colleagues as well as of himself, in a style which proves that the faculty of after-dinner speaking, rare as it is, is not denied to some of those to whom the greater qualities which make a successful investigator of Nature's secret truths have been vouchsafed in liberal measure. No one, moreover, who listened to Lord Kelvin's and Professor Huxley's most interesting speeches could doubt that this double qualification, if an exception, is an exception which comes near to proving a rule at the Royal Society's hospitable board. It hardly needs to be added that the Fellows assembled included a due proportion of the medical profession collected from London and the provinces, and that Sir James Paget's eloquent welcome of the Society's guests fitly represented this side of the great Institution's connexion with the profession of medicine.

## ROYAL BRITISH NURSES' ASSOCIATION.

### THE PETITION FOR A CHARTER.

THE Committee of the Privy Council, consisting of the Marquis of Ripon, Lord Oxenbridge, Lord Hobhouse and Lord Hannen, resumed on Monday last their consideration of the petition made on behalf of the Royal British Nurses' Association for a charter of incorporation.

Sir Richard Webster, Q.C., continued his speech for the opponents of the petition. Dealing first with the Register of the Association, he asserted that it contained not 2700 as his learned friend Sir Horace Davey had said, but only 1777 names, and that there were in the country about 5000 trained nurses and between 5000 and 15,000 more persons who might to a certain extent be allowed to come upon the Register. Of

the 1777 nurses on the Register of the Association there were upwards of 600 who had no hospital qualification at all, and a still larger number who had nothing like the three-years' qualification which was put forward as the main aim and object of the Association. Up to a certain date the Association allowed nurses on the Register without certain qualifications, and the number who took advantage of this period of grace was no less than 1623. Since that time there had not been a corresponding increase in the number registered. Each year the Association sent out a circular which did nothing more than inquire as to the accuracy of the name and address. From an examination of the present Register it was found that of the 1777 entries no less than 312 were not verified as to the accuracy of the name and address up to date. Moreover, there were objections of a more serious character. There were upon this Register the names of persons who had been dismissed for misconduct from the hospitals. Further, he might point out that no application of any kind had been made to the hospitals with reference to individuals whose names appeared on the Register.

Sir Horace Davey, Q.C., for the Association, said his instructions were to a contrary effect.

Sir Richard Webster replied that both in the case of the London Hospital and St. Thomas's Hospital no application of any kind had been made with reference to a large number of nurses whose names appeared on the Register.

The Marquis of Ripon asked whether their lordships were to understand that no application had been made to hospitals in any case.

Sir Richard Webster said he did not mean those two hospitals only, although those he was prepared to prove, but speaking for a large number of the hospitals for which he appeared—seven hospitals having training schools—no application was made to them prior to the names being placed upon the Register.

The Marquis of Ripon: In the first instance?

Sir Richard Webster replied that in a great majority of the cases no application had been made at all. Latterly there had been application made with reference to some of the nurses with respect to whom information was given, but with regard to putting the names on the Register or continuing them there no application was made either to the hospital or the training school. Proceeding with his case, Sir Richard Webster submitted that there was no precedent for such a Register as that of the Association receiving the sanction of a Royal Charter. If the Association merely wished to publish a list of their members, they could do so by their by-laws, and without the aid of a charter; but what they desired was an authentic Register to which every nurse seeking a full opportunity of employment must apply for admission. Such powers as the Association sought should only be given after a full Parliamentary inquiry, where the merits of the case could be discussed and evidence taken. The allegations he had made were supported by nine-tenths of the people who had been engaged in training nurses for the last thirty or forty years. Taking the hospitals of London, there were four with 1540 beds which supported the petition and eight with 2751 beds which opposed it. As to the provincial hospitals, there were seven which supported the petition and eleven which opposed it. In every case among the seven there were those who only gave the petition a partial support. It amounted to this, that there were altogether thirty large nurse-training institutions, of which nineteen with 6000 beds were opposed to this Register, as against eleven with 2622 beds which were wholly or in part in favour of it. Not only was the support not that of the majority of those who were skilled in training nurses, but there was excluded from the governing body, who asked by this charter to be constituted the authority for nurses, many of those ladies and gentlemen who were most competent to consider what was a proper qualification for nurses. The object of the Association was that the control of the nursing profession should be in the hands of medical men and nurses, therefore this was a point which he was entitled to press before their lordships. He might say that a charter had already been granted to the Queen Victoria Jubilee Institute. That charter did not provide for any register of nurses. In that case nurses were entitled to be members after one year's training. They were allowed to be called "Queen's nurses" and to wear a certain badge. It was surely a most remarkable thing that those Queen's nurses, sanctioned by Royal Charter and having privileges given them, would not be entitled to entry in this Register. The sting of the thing was that this would be the

Register of trained nurses for the year, meaning that those who were not upon it should not be considered trained nurses. He must humbly but firmly protest against the attitude of his clients being misrepresented or distorted. They were not there to object to a charter which would confine itself to proper work, as, for instance, the collection of funds, the improvement of nurses and the establishment of colleges; but they said that under colour of this application the Association were desirous of obtaining a chartered Register which would be the means of their holding out directly to the public that nurses who were not upon it were not trained nurses in whom the public ought to place reliance. If the procedure permitted of it, he desired to call witnesses. He desired to show that the mere standard of three years' work in nursing the sick was not by any means a satisfactory condition of the training of a nurse, and that many persons did become quite skilled and qualified in less than three years. He wished also to show that the hospitals remained in communication with their nurses for years after granting them their certificates, and could obtain information as regarded their fitness for their work.

The Marquis of Ripon said that in his experience he did not recollect any case of the kind where evidence was heard.

Sir Richard Webster submitted that if the merits required investigation some tribunal must be found for it.

Lord Hobhouse said his impression was that the points stated by counsel would not very much affect the issue.

The Marquis of Ripon said that at present he did not see any necessity for evidence, but their lordships would consider the matter.

Sir Horace Davey then replied on behalf of the Association. He understood that the opponents of the charter did not allege that the objects of the Association other than the keeping of a Register were not such as to deserve approbation and commendation, and reasonably entitle the Association to the status of a corporate body.

Sir Richard Webster admitted this to be the case, but said the whole matter was for the consideration of their lordships.

Sir Horace Davey, proceeding with his reply, said he was not surprised to find such a small proportion of nurses members of the Association, having regard to the opposition it had encountered and the misapprehension of motives, objects and aims to which it had been exposed. He denied that the Association had not applied to the hospital authorities for information prior to the registration of names, and produced to their lordships circular letters which the Association had been accustomed to send not only to the referees whose names had been furnished, but also to the hospitals concerned. This was a case in which nurses and medical men wished to manage their own affairs. They asked not to be under the complete supervision and control which apparently the training colleges desired to keep them. The question here was whether those nurses who were not on the books of the hospitals, and who had no means of getting there, were to be excluded from the exercise of their profession; whether those hospitals and training colleges were to have the exclusive right of furnishing the public with nurses. His clients desired the status of a chartered company, not to prevent other people from earning their living, but to keep a Register on which people if they thought fit could enter their names and be published to the world. There was no compulsion about the Register, it was of a purely voluntary character. It certainly would be very much better if many of the hospitals gave the Association their assistance. King's College Hospital answered their letters and gave them all the information they possessed, and if the other training schools would follow that example he thought it would conduce to improving the Register.

Lord Hannen put it to Sir Horace Davey whether the Association wished it to be clear that this only purported to be a Register of nurses who had applied to have their names put there.

Sir Horace Davey said that was already clear, but he did not object to a suitable alteration being made.

The hearing was then concluded, their lordships announcing that they did not propose to examine witnesses. It now falls to the committee to advise Her Majesty as to the course she should pursue with regard to the petition.

A NEW COMMISSION OF LIEUTENANCY has been issued for the City of London, and among the names of those who have been appointed Her Majesty's Lieutenants are the following medical men:—William Sedgwick Saunders, M.D., F.S.A., Thos. Boor Crosby, M.D., and Charles Brodie Sewell, M.D.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*On Typhus Fever at Wigan and Ince-in-Makerfield, by Dr. S. MONCKTON COPEMAN.*<sup>1</sup>—Dr. Copeman's report on this outbreak of typhus fever is of a somewhat exceptional character, for it enters with much more detail than is usual in these official reports into the clinical characters &c. of the disease. This attitude is the more fortunate because so few medical practitioners and so few health officers have now an opportunity of seeing typhus fever, and some very deplorable results have, in more instances than one, ensued, which would have been avoided had the first attacks been recognised as typhus fever in their early stages. The report has, under these circumstances, an interest quite beyond the usual health reports; and it will be read with profit by all who are likely at any time to have to identify and to treat this now uncommon form of continued fever. We are glad therefore that the report has been placed on sale. The disease commenced in Wigan in August, 1891, it reached its height in October and November, and ceased towards the end of March this year. In all, there were 78 cases occurring in 48 families, with 10 deaths. But the disease was not heard of officially until September 24th, and it was this that really led to the diffusion of the malady. Prompt isolation was instantly resorted to, but, says Dr. Copeman, "every single household invasion, with one exception, was traceable directly or indirectly" to the family of the first patient, who lived in a back-to-back house and who was assumed to have suffered from pneumonia. The spread is well indicated by means of a diagrammatic pedigree tree. Much pains was taken to trace the first case to its source, but although there seemed indications that Liverpool, where the disease constantly reappears, was the actual source, yet this cannot be said to be proved. The disease spread from Wigan to Ince-in-Makerfield, the adjoining township, and here again its nature was much obscured, by reason of an unexpected disease being classed under other headings than that of typhus fever. It is this that gives such special interest to the lengthened account of the "Clinical Considerations" which are involved and which are so well illustrated by a series of charts and tables. We believe this is the first printed report which has been issued of Dr. Copeman's work since he exchanged his labours at St. Thomas's Hospital for those at Whitehall. If it is a type of future ones, all will agree that his experience as a clinical physician has admirably prepared him for the career he has now chosen.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Birmingham Urban District.*—Dr. Alfred Hill gives the recorded death-rate for Birmingham during 1891 as 21·7 per 1000, the zymotic rate being 2·1, and the infant mortality at the rate of 171 per 1000 births. There was some small-pox in the borough and 44 cases were removed to the small-pox hospital. Scarlet fever was also prevalent, 1201 cases being placed under isolation in the hospital reserved for that disease. A general account of the sanitary work of the year is given under different headings, and a disease chart, tables &c., are added; but small-pox is significantly omitted from the chart. Dr. Hill, in dealing with the proposed new water-supply for Birmingham, refers to his inspection of the watersheds of the Elan and Claerwen, where he found the conditions eminently favourable, and, above all, such as to reduce to a minimum all chance of the possibility of any dangerous pollution. Samples of the water were taken; they are very soft, and contain some colouring matter of peat. Both these conditions remind us of circumstances favourable to the occasional taking up of lead from service-pipes, but the samples examined had only a very slight action upon the metal; and this slight amount could, it is believed, be reduced by storage and filtration.

## VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6020 births and 3694 deaths were registered during the week ending Nov. 26th. The annual rate of mortality in these towns, which had declined from 19.6 to 18.6 in the preceding two weeks, rose again to 18.9 last week. In London the rate of mortality was 17.7 per 1000, while it averaged 19.8 in the thirty-two provincial towns. The lowest rates in these towns were 13.6 in Derby, 15.6 in Bristol, 15.7 in Croydon, and 15.9 in Gateshead; the highest rates were 22.9 in Manchester, 23.1 in Plymouth, 24.2 in Halifax, 26.9 in Blackburn, and 31.6 in Salford. The 3694 deaths included 423 which were referred to the principal zymotic diseases, against 431 and 392 in the preceding two weeks; of these, 142 resulted from measles, 73 from scarlet fever, 65 from whooping-cough, 61 from diphtheria, 40 from diarrhoea, 39 from "fever" (principally enteric), and 3 from small-pox. No fatal case of any of these diseases occurred last week either in Wolverhampton or in Gateshead; in the other towns they caused the lowest death-rates in Sunderland, Norwich, Derby, and Bristol, and the highest rates in Leicester, Brighton, Croydon and Salford. The greatest mortality from measles occurred in West Ham, Huddersfield, Hull, Brighton, Croydon and Salford; from scarlet fever in Preston, Blackburn and Plymouth; from whooping-cough in Birmingham, Birkenhead, Salford and Preston; from "fever" in Swansea; and from diarrhoea in Halifax. The 61 deaths from diphtheria included 46 in London and 4 in Manchester. Two fatal cases of small-pox were registered in Leicester and one in London, but not one in any other of the thirty-three large towns; 16 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 2 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3944, against numbers declining from 4067 to 4045 at the end of the preceding three weeks; 302 new cases were admitted during the week, against 403 and 404 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 357 and 340 in the preceding two weeks, rose again to 353 last week, but were 90 below the corrected average. The causes of 79, or 2.1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Leeds, Sunderland, and in six other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Blackburn, Huddersfield and Sheffield.

## HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20.6 and 21.5 per 1000 in the preceding two weeks, rose again to 23.7 during the week ending Nov. 26th, and exceeded by 4.8 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13.6 in Paisley and 13.7 in Perth to 24.0 in Edinburgh and 58.0 in Leith. The 661 deaths in these towns included 104 which were referred to measles, 28 to scarlet fever, 9 to diphtheria, 9 to whooping-cough, 7 to diarrhoea, 4 to "fever," and 1 to small-pox. In all, 162 deaths resulted from these principal zymotic diseases, against 110 and 127 in the preceding two weeks. These 162 deaths were equal to an annual rate of 5.8 per 1000, which exceeded by 3.6 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 61 and 65 in the preceding two weeks, further rose to 104 last week, of which 41 occurred in Leith, 29 in Edinburgh, 16 in Glasgow, and 13 in Aberdeen. The deaths referred to scarlet fever, which had increased from 13 to 24 in the preceding three weeks, further rose to 28 last week, and included 18 in Glasgow and 6 in Leith. The 9 fatal cases of diphtheria also showed a further increase upon recent weekly numbers, and included 3 in Glasgow and 3 in Edinburgh. The 9 deaths from whooping-cough exceeded by 2 the number in the previous week, and were all recorded in Glasgow, where the fatal case of small-pox also occurred. The deaths referred to diseases of the respiratory organs in these towns, which had been 142 and 137 in the preceding two weeks, were 141 last week, and were less than half the

number in the corresponding week of last year, when an epidemic of influenza prevailed. The causes of 59, or nearly 9 per cent., of the deaths in the eight towns last week were not certified.

## HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23.9 per 1000 in each of the preceding two weeks, declined to 22.8 during the week ending Nov. 26th. During the first eight weeks of the current quarter the death-rate in the city averaged 23.1 per 1000, against 17.9 in London and 21.9 in Edinburgh. The 153 deaths in Dublin during the week under notice showed a decline of 7 from the number in the preceding week, and included 4 which were referred to "fever," 2 to diarrhoea, one to whooping-cough, and not one either to small-pox, measles, scarlet fever, or diphtheria. In all, 7 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.0 per 1000, the zymotic death-rate during the same period being 1.7 in London and 7.3 in Edinburgh. The deaths referred to different forms of "fever," which had declined from 10 to 2 in the preceding three weeks, rose again to 4 last week. The fatal cases of diarrhoea, which had been 2 and 5 in the preceding two weeks, declined again to 2 last week. The 153 deaths registered in Dublin last week included 25 of infants under one year of age and 41 of persons aged upwards of sixty years; the deaths, both of infants and of elderly persons, showed a slight decline from the numbers recorded in the preceding week. Three inquest cases and 4 deaths from violence were registered; and 53, or more than a third of the deaths, occurred in public institutions. The causes of 10, or nearly 7 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

## MOVEMENTS OF MEDICAL STAFF.

SURGEON-COLONEL WADE, Brigade-Surgeon-Lieutenant-Colonel Elvatt, Surgeon-Captains Elkington and McCree have arrived from India. Brigade-Surgeon-Lieutenant-Colonel Burnett has been appointed to Permoy. The following Officers have embarked for India in the *Serapis*:—Surgeon-Major J. F. Brodie and Surgeon-Captains de Courcy Scanlan, Faichnie and Kirkpatrick. Surgeon-Major Martin has arrived in Bombay and Surgeon-Captain Allport in Ceylon. Surgeon-Captain Hale has been appointed to the Eastern District, Surgeon-Captain Burton to Lichfield and Surgeon-Captain Wiles to Hulme. Surgeon-Captain Beatty has embarked for Sierra Leone. Surgeon-Major H. Saunders, now at Malta, has been appointed to the King's Dragoon Guards, now forming part of the Queen's Guard at Windsor.

## INDIAN MEDICAL SERVICE.

The following Surgeon-Majors who have completed twenty years' full-pay service have been appointed Surgeon-Lieutenant-Colonels:—Mathew Denis Moriarty, M.D.; Gordon Price, M.D.; Edward Beville, M.B.; Bartholomew O'Brien, M.D.; Henry Walter Hill, M.D.; Zalnor Allee Ahmed, M.D.; William Arthur Gilligan and William Edwin Griffiths. The following Surgeon-Captains having completed twelve years' full-pay service are promoted to Surgeon-Majors:—George Michael James Giles, M.B.; Arthur Robert Wyatt Sedgfeld, M.B.; Edwin Francis Horatio Dobson, M.B., Johnston Shearer, M.B.; Hem Chandra Banerji; Shambu Chandra Nandi, M.B.; Francis Samuel Peck and William Deane. The services of the undermentioned Medical Officers have been replaced at the disposal of the Government of Madras:—Surgeon-Major J. C. Marsden and Surgeon-Major R. Pemberton. Surgeon-Major D. S. E. Bain has been appointed Civil Surgeon of Coorg. The services of Brigade-Surgeon-Lieutenant-Colonel R. Bowman, Residency Surgeon in Turkish Arabia, have been replaced at the disposal of the Bombay Government. Surgeon-Major F. Day, attached to the Station Hospital at Deolali, has been transferred to the Station Hospital at Colaba. Surgeon-Lieutenants T. Jackson, F. E. Swinton and S. H. Burnett, Medical Staff, on arrival from England, have been ordered to Poona to be attached to the Station Hospital at that Station. The services of Surgeon-Colonel Richardson, Officiating Surgeon-General with the Government of India, are placed at the disposal of the Government of the North-West Provinces.

## NAVAL MEDICAL SERVICE.

The following appointments have been made:—Surgeons: H. S. Archdell, F. H. Clayton, R. J. Fyffe, P. Lord, F. J. A. Dalton, P. M. May, C. L. Bunton, F. D. Lumley, H. E. Tomlinson, A. S. G. Bell and B. Gilpin to the *Victory* additional for hospital; D. J. P. McNabb to the *St. Vincent*. Surgeon and Agent: J. E. F. Andre, at Chicester Harbour, East Wittering, Thorney and Selsey. The following qualified candidate for the Naval Medical Service has been appointed Surgeon in Her Majesty's Fleet:—Edward Thomas Meagher.

## VOLUNTEERS.

The following promotions have been made:—2nd East Riding of Yorkshire (Western Division Royal Artillery), Surgeon-Captain J. Sherburn, M.B., to be Surgeon-Major; 1st Herefordshire, Surgeon-Lieutenant. J. W. Hinings to be Surgeon-Captain; 2nd (Westmoreland) Volunteer Battalion, the Border Regiment, William Baron Cockill, Gent., to be Surgeon-Lieutenant.

## THE VOLUNTEER OFFICERS' DECORATION.

This decoration has been conferred upon the undermentioned officers.—*North-Eastern District*: 1st Berwick-on-Tweed, Surgeon-Major George Bolton; 2nd Durham (Seaham) (Western Division, Royal Artillery), Surgeon-Lieutenant-Colonel Thomas Carlyle Beatty and Surgeon-Lieutenant-Colonel Thomas Gibbon; 4th Durham (Western Division, Royal Artillery), Surgeon-Lieutenant-Colonel Samuel Gourley; 1st Lincolnshire (Western Division, Royal Artillery), Surgeon and Honorary Surgeon-Major Thomas Small, retired, and Quartermaster and Honorary Captain Richard Varley; 2nd West Riding of Yorkshire (Western Division, Royal Artillery), Surgeon-Lieutenant-Colonel Harry Meade; 2nd Volunteer Battalion, the Northumberland Fusiliers, Surgeon-Major Adam Wilson; 1st Volunteer Battalion, the Lincolnshire Regiment, Surgeon-Lieutenant Hugh George, M.D., Surgeon-Major John West Walker, M.B., retired, and Surgeon and Honorary Surgeon-Major Charles Bartholomew Moody, retired; 3rd Volunteer Battalion, the Prince of Wales's Own (West Yorkshire Regiment), Brigade-Surgeon-Lieutenant-Colonel Jas. Scarborough Loe; 1st Volunteer Battalion, the Leicestershire Regiment, Surgeon and Honorary Surgeon-Major Edwd. Rawson Denton, retired; 1st Volunteer Battalion, the Duke of Wellington's (West Riding Regiment), Surgeon-Lieutenant-Colonel J. E. Foster; 2nd Volunteer Battalion, the Sherwood Foresters (Derbyshire Regiment), Brigade-Surgeon-Lieutenant-Colonel William Milligan and Surgeon-Lieutenant-Colonel Edward Mason Wrench; 1st Nottinghamshire (Robin Hood) Rifle Volunteers, Surgeon-Lieutenant-Colonel Thomas Wright and Surgeon-Major John O'Connell Hynes; 2nd Volunteers Battalion, the York and Lancaster Regiment, Brigade-Surgeon-Lieutenant-Colonel John Blackburne, Brigade-Surgeon-Lieutenant-Colonel John Mitchell, and Surgeon and Honorary Surgeon-Major Charles Natrass, M.D., retired.

## VOLUNTEER MEDICAL STAFF CORPS.

Maidstone Division: Surgeon-Lieutenant-Colonel David Henry Monckton, M.D.—*South-Eastern District*: 1st Sussex Artillery Volunteers (Eastern Division, Royal Artillery), Surgeon-Major William Seymour Burrows; 2nd (the Weald of Kent) Volunteer Battalion, the Buffs (East Kent Regiment), Surgeon-Lieutenant-Colonel Henry Benjamin Wood, M.D., retired; 2nd Volunteer Battalion, the Royal Sussex Regiment, Brigade-Surgeon-Lieutenant-Colonel Charles Francis Lewis. *Woolwich District*: Surgeon-Lieutenant-Colonel William Warman Coleman, retired.

## A SYSTEM OF SANITARY LEGISLATION FOR INDIA.

Brigade-Surgeon-Lieutenant-Colonel Climo has recently published an elaborate pamphlet on "The Hygienic Conditions of Indian Cantonments." He contends that subsoil sewage pollution has been the result of more or less chronic surface impurity, resulting from the over-population of limited areas coupled with defective or inadequate sanitary measures. He points out that the present hygienic conditions of Indian cantonments all tend to pollute occupied areas with organic refuse and to give rise to a sewage-loaded soil which breeds enteric fever. He argues that a system of sanitary legislation should be organised and adopted for India on similar lines to that which is pursued in Great Britain, and advocates the formation of a central sanitary authority entrusted with certain powers by the Government of India, and acting under the orders of the Commander-in-Chief, together with a local sanitary authority for each canton-

ment acting in concert with, but subordinate to, the central one. This organisation would, in reality, constitute a public-health department with power to initiate sanitary work, make by-laws, and enforce the application and execution of sanitary measures, and exercise generally a sanitary supervision over all matters affecting public health in and around cantonments.

## MEDICAL OFFICERS AND NATIVE STATES.

Our Indian contemporary, the *Civil and Military Gazette*, recently published an article setting forth the difficulties which the Punjab Government had got into with the leading Punjab chiefs in the matter of medical advice. The Rajah of a native state, like other people, naturally desires to choose his own medical adviser, and applies to the Government for permission to have the services of the medical officer of his choice; the Punjab Government, on the other hand, is desirous of making the selection for him. Of course the Local Government is acting strictly within its rights and powers in this matter, but the wisdom and expediency of the course are not very apparent. Anyway, the native chief, failing to get the particular medical officer he wants, goes elsewhere to secure a medical adviser, and the appointment is lost to the medical service in India. It is unfortunate, says the *Civil and Military Gazette*, that this question of medical service by British officers in native states, which ought to be fruitful of political good, should become a source more fruitful of irritation and friction than anything else.

## THE ARMY MEDICAL STAFF.

It is stated, on the authority of the *Broad Arrow and Naval and Military Gazette*, that Sir William Mackinnon, the Director-General of the Army Medical Department, has given the following opinions on points referred to him by the Secretary of State for War: (1st) That as regards foreign service he is in favour of reverting to the old tour of five years for India; (2nd) that as to purely military titles, although personally adverse to them, he has been bound to allow that the large majority of his officers are in favour of their being conceded; (3rd) that the formation of a Royal corps has his emphatic approval; (4th) that interference with his power to sanction or object to exchanges is to be deprecated. We need scarcely add that we concur in these views; for we have always been opposed to the increase of the length of foreign tours as prejudicial to medical officers in many ways, especially as regards health; and years ago, when the regimental system was in force and the adoption of the present unification system was under discussion we strongly advocated the formation of a Royal Corps of Surgeons or a Royal Medical Staff Corps. As this has since been recommended in the reports of committees, and is, in our opinion, a fit and proper designation for such a large and important body as the medical staff, we trust that Mr. Campbell-Bannerman, the new Secretary of State for War, may see his way to giving effect to it. We are of opinion that exchanges between medical officers should be allowed subject to the approval of the head of the department.

## AGE RETIREMENTS OF MEDICAL OFFICERS.

On a late occasion we did not discuss this question because we did not consider that, in the case alluded to, it admitted of doubt, or that there was any intention on the part of the head of the Medical Department of departing from the course laid down in the regulations of the service. The question of compulsory retirement has again arisen, however, in connexion with the rank of Surgeon-Major-Generals. We can only repeat now what we have always held and urged, that, as a matter of principle and as the only just and fair method of administering a large department, the Royal warrants and regulations in force at the time should be strictly adhered to. The terms of existing regulations, no doubt, admit of the retention of officers under exceptional circumstances for the absolute good of the service, but such cases should be very rare and should be provided for, in our opinion, at the expense of the State, for whose benefit they are made. Officers so retained should be seconded in order to prevent blocks in promotion and injustice to others; and this must, we imagine, commend itself to all as a just and fair principle of administration.

## THE ARMY MEDICAL STAFF CORPS.

In order that it may not escape the notice of officers of the Medical Staff, who are naturally interested in all that concerns the good name and welfare of the men of the Medical Staff Corps, we think the recent decoration of First-Class Staff-

Sergeant Charles Williams of that corps should be recorded. Her Majesty at Windsor Castle on the 25th ult. decorated the Staff-Sergeant for distinguished conduct in the field, and especially at the engagement of Abu Klea where Colonel Burnaby was killed. As the square was being hardly pressed by the enemy Staff-Sergeant Williams and the other members of his corps, about fifteen in number, heroically rushed from time to time from the ranks and rescued some eighty or ninety wounded soldiers lying upon the field and successfully conveyed them to the shelter of the inside of the square. Staff-Sergeant Williams and the Medical Staff Corps were exposed to a galling fire from the Soudanese, and the rescuing of the wounded under the circumstances was very risky work. Those who have had experience of some of the fighting in Egypt and of the impetuous valour of the Arabs, which has been graphically depicted in Rudyard Kipling's verses, can best understand the plucky nature of the service rendered.

## Correspondence.

"Audi alteram partem."

### "EXPERIMENTS ON ANIMALS."

To the Editors of THE LANCET.

SIRS,—First a word in reply to Mr. Bowreman Jessett's letter, which consists of a series of questions, most of which are conundrums. He says he can find no mention of my method of flap-splitting for the purpose of intestinal repair in any of the surgical literature at his disposal; yet if he will turn to Vol. III. of the Transactions of the British Gynaecological Society, page 367, he will find what he wants not far from his elbow. I have not yet fully published my views on intestinal surgery; I have had so many much more important questions to settle that such little by-paths as that in question have to wait. Yet I am sure no one will quarrel with me as being a person of idle or neglectful habits, nor can I say that the medical societies or the medical journals have been churlish of placing their opportunities or their space at my disposal. Truly I find art long and life brief, and, struggle all I can, time fails me to get out my second volume, in which such details as Mr. Jessett wants will be found more fully recorded. He misrepresents me entirely when he says that I would not have any operation done on myself save as I do it. What I did say is that I would not submit to any operation myself save what I do on others. I would not submit to pylorotomy, for instance, or gastro-enterostomy, or to any of those nonsensical proceedings which give no ultimate benefit. Now, as to your leading article on this subject. I have no right to thank you for it, but I do so most heartily, for it indicates a new departure, and a very wise one, in this discussion, and I do not fail to recognise most gratefully your kindly intent towards myself and my attitude upon this troublesome question. It has been all my life my misfortune to live and grow in an atmosphere of minorities, and that is always a source of trouble. In politics, religion, ethics and medicine it has always been the same, and I have come to regard the resulting warfare and struggle as inevitable. I have already lived to see many of my minorities turned into consenting majorities, and I am hopeful to see the same result follow in other instances, and your article is one which gives me hope about vivisection. You do me justice when you say it is on the utilitarian standpoint that I take the issue. As a Radical I hate standing armies and war and all that belongs to it; but I should, like the Quaker, say to a boarding-enemy, "Friend, thou hast no business here," and pitch him overboard if I could.

You say that the discussion of the question of experiments on living animals has passed beyond the stage of recrimination. I confess I wish this were true, but certainly within the past few weeks it has been shown to be not the fact. I trust that I may be believed when I say that I have during the past fourteen years, in which I have taken part in the controversy from time to time, done my very best to induce those whose views I share to use moderate language. I have not always succeeded, I am sorry to say; but for myself I desire once for all to say that I deeply regret any word and every word that I may have used without due care, and

which may have caused anyone who does not agree with me the slightest pain. Anything which I may have said which deserves this apology has been said under provocation, and of that I have had more than a fair share.

You submit two questions for discussion, and I agree with the postulates entirely if you will change the verb of the present tense into the past perfect, and say: "1. *Have* experiments on animals *been* justified by the results obtained? 2. *Have* such experiments *been* carried on under proper restrictions and by qualified and humane investigators in this country?" You give an unqualified affirmative in answer to the questions in the present tense; but can you do so with equal assurance if the past perfect tense is used? For the public it is by the evidence of the past that suspicion is raised concerning the present, and when I find an all-round defence of the past entered into by sweeping general statements I cannot wonder at them doubting the present. The worst enemy of the man who honestly desires to aid the advance of his profession by modern research is the exalted physician and surgeon or the misguided journalist who testifies that in the past everything has been useful and good. A common-sense attitude to take would be that in times of old rough methods were used, often fruitlessly and with misleading results. At odd times we may have to revert to such methods, just as in abdominal surgery we have now and then to go back to the caution to arrest bleeding. But to bring back the illustrations of Harvey's well-meant and inevitable bunglings, or Everard Home's misunderstanding of Hunter's clinical reasoning, as illustrations of what is necessary now in methods for everyday and wholesome use is unreasonable, is fallacious and, from a political point of view, is dangerous. Even in the illustration of Von Graefe's work, ignorant though I am of modern ophthalmic surgery, I now know that I was quite right and that Von Graefe's conclusion was a purely empirical one, and not based—not even confirmed—by experiments on animals. Similarly I might assure you, did your space and the patience of your readers permit, that in my own department the labours of Pasteur and Lister had not only nothing to do with my success, but, on the contrary, my success only came to me when I had completely disregarded the entanglements into which their teaching had led me. Since I left their following I have ceaselessly been engaged in combating their mistaken application of the facts relating to dead tissue to the treatment of the living.

But a truce to polemics. Your article deserves thanks, not contention. You are kind enough to say I am a keen, perhaps an obstinate, controversialist, and that you hope I may be ere long convinced that there is some good in vivisection. Would you be surprised to hear that I have admitted as much long ago, and who could doubt it after the masterly (no word is too good for it) unravelling of the sardine poisoning case the other day by Dr. Stevenson? This prince of toxicologists "vivisected" some mice and guinea-pigs, and proved his case; but with it all there is a suspicion in my mind that if modern chemistry would give itself up to such work seriously, that splendid science could prove the presence of these mysterious poisons in a way far better than that of trusting to the random medieval method of poisoning mice and guinea-pigs. The spectroscope solved in a trice the other day the mystery of the "winking star" for the astronomer. Is not the possibility of sardine poisoning, open to all and any of us, a far more important matter than the size and shape of the orbit of Algol? It seems to me a rank discredit that we have to plead a necessity for vivisection in any case. It is so transparently unscientific—that is, inexact. Let my brethren bear in mind that this method of research after knowledge, be it useful or be it useless, stands absolutely alone in being objectionable to anyone. Not the astronomer, nor the chemist, nor the physicist, nor any one else among scientific men has had to defend or excuse anyone of his methods of research. Is it not time that we began to at least apologise for this *déte noire* of ours? Not to defend it, but to express sorrow that our methods are so primitive, our science so crude, that it is still necessary—if it really is so. Further, should we not say that we regret it; should we not undertake to restrict it as far as possible, and keep it out of the horrors of the past as much as we can? And then, should we not religiously and zealously move with all our might to replace it by better methods and exhaust all other methods first?

Even these protestations—and the bulk of us would be honest in them—would go a long way to keep moderate—

minded men on our side, but to make an all-round defence of everything that has been done is mere folly.

I am, Sirs, yours truly,  
Birmingham, Nov. 28th, 1892. LAWSON TAIT.

### "DEATH FROM IRRITATION OF ASCARIDES."

To the Editors of THE LANCET.

SIRS,—I think I may claim to have strong testimony to support Dr. Beaven Rake's contention in your last issue of the important part which human entozoa play in the etiology of disease. I have just completed a voyage in charge of 557 Indian coolie emigrants from Calcutta to Demerara that occupied eighty-seven days. Last year, from symptoms I observed in a similar cargo bound to Jamaica, I was led to suspect the general presence of round worms in Indian coolies. Gripping pains, obstinate sickness and the presence of whitish shiny stools streaked with blood and passed with great frequency, and tenesmus, and the fact that these stools were extremely offensive, quite unaccompanied by dysenteric collapse and formed the commonest symptom observed, all appeared to point to this cause. This year, within a fortnight of embarkation, I weighed every coolie, and then administered santonin to each emigrant above two years of age, which produced 989 round worms. The largest number produced by any individual was thirty-seven, but I have good reason to suspect that large numbers escaped my tally, both in the preliminary sea-sickness which attacked the entire shipment and also from their belief that a second dose of medicine would be the inevitable result of such a confession. Allowing a two months' interval to elapse, I again weighed every coolie on board the ship, and I was able to prove a net increase of 2420 lb., which, taking 110 lb. as a fair average weight for an adult, represented twenty-two extra labourers on board. This result, though doubtless due to the generous dietary provided by the Colonial Governments in some part, may, I think, be not unfairly attributed to the fact that this large number of round worms had been expelled which would otherwise have caused grave interference with the digestive functions and prevented the due assimilation of food products. In conclusion, I would mention that in one case, a child aged two, who died, no symptom save debility could be discovered, and upon making a post-mortem examination a round worm was discovered in the small intestine, but no further evidence of visceral disease.

I am, Sirs, your obedient servant,  
PERCY RENDALL, M.D.  
Devonshire Club, St. James's, S.W., Nov. 28th, 1892.

### "MEDICAL AID ASSOCIATIONS."

To the Editors of THE LANCET.

SIRS,—I have always been disinclined to enter on a newspaper controversy, which as a rule results in so little good, but I cannot allow the assertions of Dr. Leslie Phillips and others to pass unchallenged. As to the working of medical aid associations in other towns I know nothing, but I must emphatically deny that the Manchester United Friendly Societies' Medical Association, of which I am one of the surgeons, trade on the services of their medical officers and make a profit out of their work. The published report and balance sheet of that Association for last year show a balance to their credit of £14 9s. 2½d. (no interest at all having yet been paid on money borrowed for fitting up surgeries &c.)—not much of a profit for twelve months' work. I am confident that the first use to which a larger balance will be put will be to increase the salaries of their surgeons (in the case of one this has already been done unasked) or to lighten their work by opening another surgery, thus dividing Manchester into four districts instead of three, as at present. No canvassing for families is carried on here, the only eligible ones being those of members of one of the societies forming the Association, and as far as I have been able to see the only reason for combination is the benefit of the members, as under the present system they obtain the services of a medical man who devotes himself entirely to attendance on them, and with whom the question of expense does not arise, he being able to obtain anything necessary for their efficient treatment for the asking. Looking at the matter from the club's point of view, I quite agree with

this. Medical men admit that the remuneration from clubs is too small to expect proper attendance, and from my experience as an assistant—which has been extensive—I should not care to be treated as a club patient in the usual way. No profit is made out of our attendance on midwifery; the whole of such fees, together with those for vaccination and reporting infectious cases, belong to the surgeons. Further, no "covering" of unqualified men can occur, as there are no assistants.

I entirely fail to see in what way my conduct can be considered "infamous in a professional respect." Nothing could be more contrary to my intentions, and when it is shown that I am acting in any way derogatory to my profession I will resign without any coercion from the Medical Council, who will, I feel sure, first consider many other matters—really disgraceful to the profession of medicine before they are induced to interfere in this. There can surely be nothing wrong in my preference of an appointment worth almost double that of an ordinary assistantcy, or in being responsible to a lay committee and paid by them. The medical staffs of all hospitals are controlled in like manner, and the appointments to large works, collieries and unions are held under both such conditions. So far I have been treated with every consideration, and am perfectly uncontrolled so long as my duty is done towards the sick members; and I certainly cannot be dismissed without three months' notice, unless for gross misconduct. I honestly believe I am practising my profession in a perfectly honourable and legal manner, and am free from the jealousy and ill-will found amongst my medical brethren in private practice, caused by the struggle to obtain patients. At any rate, I prefer my present position to running a sixpenny dispensary, or a private club (admission fourpence per family per week), or acting as assistant to another man, working like a slave, entirely for his interest and profit, for a mere pittance, and having one's opinion and treatment regularly and unceremoniously set aside and the impression conveyed to patients that an assistant is altogether an inferior being; or if perchance he should become too popular, some excuse for dismissal is soon found, and this to a married man is a serious matter, all chance of a livelihood in the same neighbourhood being quite out of the question through the terms of a stringent agreement. I should also be glad to know in what way my attendance on a number of united clubs differs from that of any other medical man on a single one, the contribution per member for the medical attendance being exactly the same in each case. Naturally I should, in common with most men, prefer a lucrative private practice, but to a young medical man without means this at the outset is impossible; but in simple justice, judging by my own treatment so far by a medical association, he might do worse than accept one of their appointments, which, with stated surgery hours, rules as to the sending of messages, holidays &c., is in some respects preferable to private work.

I am, Sirs, yours faithfully,  
Manchester, Oct. 24th, 1892. VERNON MOSSMAN.

To the Editors of THE LANCET.

SIRS,—Brevity is so important to us all that I must ask you to excuse me if I imitate, in a minor degree, the curtness of such succinct phrases as "systematic robbery" and "grotesque indecency," and request my opponents to translate my terse expression into more diffuse and polite language. Most of the letters of the malcontents are simply nonsense. Here is a quotation from one of them: "He [the surgeon] is the paid servant of some person or persons not connected in any way with the medical profession. This is a most undignified and indefensible position." Thus this correspondent, in order to prove his own conduct infamous, calmly insults the medical staff of the Army, the Navy, the Poor-law Unions, County Councils, and many other bodies. The next sentence in the same letter accuses me of incompetency because (not having capital) I cannot get a larger income in private practice than I have at present. I confess I can produce no reasoning which could make an impression on this gentleman, and I therefore pass by his three letters without further notice. Another correspondent asks me to master the facts in the case of the gentleman who received only £250 a year after five years' service, though the writer must know that the officer referred to was paid much more than the "market value" of medical men with such, and so recent, qualifications. If the advertisements are an index the L.S.A. of recent standing can be employed for £60 a

year, in-doors, and I have not heard of one who would sneer at the larger salary named. The subject is unpleasant and I quit it with pleasure, even to point out the remarkable mistake of another writer who speaks of the associations as "charitable institutions," the very thing they are not. He goes on, indeed, to propose that when all expenses have been paid the members should offer the rest of their pence to the surgeon; but whatever future claim such actions may give them to be considered charitable they have none at present. One of our opponents estimates the applications for a vacant appointment on our staff at forty, another at fifty, and they thus expose the baselessness of all the talk about our salaries being "miserable pittances," our condition "servitude" and our employers "sweaters." This one fact, that we are envied by a body of medical men at least forty or fifty times as numerous as ourselves, shows beyond dispute that if we are badly paid, enslaved and "sweated" by our employers, a vast number of qualified men must be treated still more badly by their employers. Why, then, waste sympathy on us, when we are, comparatively at least, well off? At the same time, if there are any better positions to be had, we shall be glad to hear of them, and, if we can get them, we shall, I promise, resign our present appointments in a body. None of your correspondents have succeeded in framing a definition of "covering" which would include us and exclude the man who takes up a deceased brother's practice on condition of sharing the proceeds with the widow, or him who buys a practice with borrowed money and goes shares with the money-lenders. If any financier will advance me £2000 on my guaranteeing him half the net profit of the practice I should buy, I shall be delighted to become working partner in the firm thus formed, and so, I do not doubt, would many of my opponents. And now I turn to Dr. Phillips' statements, which are like the talk of one thinking aloud, flinging among us half-formed ideas which he has never criticised himself nor expected anyone else to criticise. Take the assertion that the medical officer does all the work and earns all the income of the Association. Work is done for it by herb collectors, farmers, miners, merchants and drug millers, by the labourer and his men, by the dispenser, by those who have built the surgery &c., by the secretary or collector, by the committeemen (who see that each official does his duty), and by many others. The Association, needing the product of their labour, pays for the work they have done, and, needing also a doctor, pays him. The assertion that the latter does the work of all the others deserves to be met with a burst of laughter. Take next the statement that the Associations practise. Ten thousand men and women and 4000 babes in Northampton are solemnly declared to carry on a medical practice, and the medical officers are said to "cover" or conceal the nefarious doings of this army of unconscious quacks. Comment is needless. Take, then, the assertion that "the privilege of practising medicine for gain does not exist without the licence," and think of all the unqualified assistants, all the prescribing chemists and all the herbalists. Remember that the law prevents *no one* from practising for gain. Take, next, the insinuation that a qualification has no value if laymen can invest money in practices, and call to mind that it is the qualification which makes them prefer us to quacks, and that in the clerical profession the laymen do *all* the buying and selling, the clergyman being obliged to swear that he has not paid and will not pay for the adwoson, and yet the clerical "qualification" has not lost its value. Dr. Phillips wastes a column in describing an imaginary prospectus which "could be drawn" by a company which "may" be formed, when a moment's reflection would have shown him that he was not dealing with the question at issue. Are we justified in acting as we do? That is the question; and the assertion that if we are justified certain others would be so is totally irrelevant. More than another column is devoted to declaring the difference between "combination" and "coöperation," as if we cared which word was employed. Bishops may combine and burglars coöperate, and the suggestion that the one word has a baser meaning than the other is not supported by any lexicographer or philologist. The idea of restricting the meaning of an English word—the derivation given is not quite correct, by the way—because of the meaning the Romans attached to certain similar words would be unworthy of a third form schoolboy. In reply to the statement that the Aids do not abolish middlemen, I beg to point out that medical men employing assistants are middlemen, and of the worst description, as they intercept over three-fourths of their assistants' earnings. The Aids, as I explained in a pre-

vious letter, supply the assistant with an equivalent for capital, and, besides providing him with all that is required for carrying on a practice (which a private practitioner has to pay for himself), give him a salary. Nearly the whole income is spent in this way, a very small sum being usually put by as security for the stability of the Association. The Medical Defence Union itself is a "legal" Aid Association, the lawyers doing much more of its work than we do of the Aids, and receiving only one-third of the income. The Union saves, pays rent, and employs other servants than its professional men, just as do the Associations, but while the latter pay their lay officers only 4 per cent. of the receipts, the former pays its secretary and clerks 8 per cent. The comparison is made closer by the fact that, though the Union sneers at the Aids as "trading companies," it describes itself, in a report now before me, as "a business company and not a learned society." The most baseless of all Dr. Phillips' assertions is that the Aids pay "as a rule from one-fifth to one-third of the income" to their medical officers. It appears from the reports, which are said to "substantiate" this statement, that they pay "as a rule" from 40 to 50 per cent.—a larger proportion than most medical men can devote to absolutely private purposes, and that no Association pays so little as one-fifth. May I ask its author to withdraw this erroneous assertion? I have no time now to show the worthlessness of the remedies mentioned, but if the surplus is to be divided among a portion of the Association's servants, of course the members will take care that there is no surplus; and the suggestion that we should derive profit from having the supplying of drugs in our hands strengthens the impression that the "club doctors" gave cheap drugs in improperly small doses. In conclusion, I wish to say that I think this attack is made on us at the instigation of the general practitioners, who wish to become "club doctors" once more, and to force us to serve them (for £60 in-doors) as of old. Hoping that this letter may induce your other correspondents to *think* on the subject, and cease to rush into print with raw opinions and impossible suggestions, I am, Sirs, yours truly,

Nov. 28th, 1892.

VERAX.

\* \* We have received an overwhelming amount of correspondence on this subject. We do not propose, however, to insert any more letters for the present, the matter having been referred by the General Medical Council for consideration by a committee—ED. L.

## DEATHS UNDER CHLOROFORM.

*In the Editors of THE LANCET.*

SIRS,—A patient aged fifty-seven was admitted to the infirmary on Nov. 9th, 1892, under the care of Dr. Carter, suffering from ascites, which was thought to be complicated by a tumour (? cystic) in the right pelvic region. The patient's consent having been obtained, it was decided to operate, and for this purpose she was transferred to Mr. Jordan Lloyd. On Nov. 12th, the heart having been examined, and being to all appearances healthy, chloroform was administered on a piece of folded lint. (Chloroform was given in preference to ether because of an asserted liability to pulmonary trouble.) The patient took the anæsthetic perfectly well and was in no way excited, respiration continuing evenly and deeply at normal rapidity up to the time when the skin incision had been made, when quite suddenly and without warning she became livid, made two or three shallow gasps, and breathing ceased. The heart was examined instantly and no sounds could be detected. The pupils were not dilated, being about a line in diameter. The tongue was well forward between the teeth during the administration. The head was lowered over the end of the table and artificial respiration, both by Silvester's and Howard's methods, commenced, but no air could be made either to enter or leave the chest. Insufflation of the lungs was tried by the mouth without effect; tracheotomy was then performed and insufflation again attempted through the tube, but without effect. Heart puncture made within a few minutes of the onset of alarming symptoms showed the cardiac muscle to be absolutely inactive. At the post-mortem examination the cardiac condition was not such as could be recognised by auscultation, there being no valvular lesions; nor was the condition of the heart muscle such as could have affected the duration and tone of the first sound in any marked degree.

Chloroform from the same bottle had been administered to a case by me on the previous day, and was given to another patient afterwards without any disturbing effect. The amount administered in this case was not accurately measured, but could not have exceeded half an ounce; and the patient was completely, but by no means deeply, under when the alarming symptoms arose. I am inclined to believe that respiration and circulation ceased simultaneously; but I am of opinion that the symptoms were due to respiratory cessation, aided by the upward displacement of the diaphragm from the abdominal fluid, the heart's cessation being secondary. I would call particular attention to the following—(1) The normal size of the pupils; (2) the position of the tongue; (3) the sudden development of the condition; (4) the lividity of the face throughout in the entire absence of obvious signs of laboured breathing; (5) the early arrest of the heart's action, as discovered by auscultation and puncture; (6) the complete failure from the first to make air enter or leave the chest by any artificial methods. I may add that during a fair experience of anaesthetics, both in the hands of others and myself, I have never known alarming symptoms come on so suddenly and all efforts from the first prove so absolutely futile; and this case, in my opinion, lends support to the view, now so commonly held; that in the vast majority of cases of death under anaesthesia respiratory failure plays the leading part.—I am, Sirs, yours obediently,

F. MORRIMER ROWLAND, M.B. Cantab.,  
Resident Medical Officer, City Infirmary.

Birmingham, Dec., 1892.

To the Editors of THE LANCET.

SIRS,—It is a far cry from you to where I am writing, but after waiting in vain for some more doughty champion of chloroform to appear, especially one from the Edinburgh school, I venture to raise my feeble voice, impelled thereto by what seems to me only just and fair to the merits of this useful servant of our profession, but one which appears liable to become decidedly unruly in use, and unusually fatal to our unhappy patients. I take it that the conclusions of the Hyderabad Commission have settled it that the respiratory centres are the first in order to be affected, and the rule to watch the respiration is a sound one. I make bold to broadly lay it down that there are two classes, and two only, where death occurs under the use of this anaesthetic, and these classes are—(1) unsuitable cases, and (2) unsuitable apparatus.

1. *Unsuitable cases.*—As regards these I opine that we are all agreed that they consist of those where some organic disease of the heart and lungs exists, likely to be influenced by the drug, and to these we should perhaps add any affection of the centres presiding over the circulation and respiration.

2. *Unsuitable apparatus.*—Here I have been struck by the remarkable preponderance of the use of some one of the numerous inhalers in fatal cases. It is my firm conviction that if all apparatus are carefully deposited in the lumber room, out of the reach of the scientific mechanic, we would be gratified by a decided decrease in the number of deaths reported. Roughly speaking I think it will be found on an analysis of every case of death from chloroform narcosis that where death has not been the outcome of organic disease, the existence of which was unascertained, unsuspected or overlooked, it has been the result of the use of some inhaler or other. For my part I have ever since my student days used the folded towel applied over mouth and nose, ensuring a due admixture of air with the vapour. If ever I did have recourse to any other method I soon saw reason to return to the time-honoured, simple and useful towel or napkin folded crosswise. Keeping this towel well before the nose and mouth I keep my eyes upon the respiratory movements and regulate the administration accordingly. I feel as I write this that it must seem very platitudinous, as it has been urged and recommended again and again, but apparently to deaf or preoccupied ears. I have never had since a student any mishap in giving it, and I have given it to all sorts of cases, and numberless times and often, when far away from medical assistance, alone. I therefore cannot help wondering how it is that all the deaths occur which one sees recorded. As an improvement to your present heading, then, I would suggest "Deaths under Inhaler." In thus speaking of chloroform I do not of course pretend that it is any safer than ether, and do not decry the latter; but I only desire to put the saddle on the real delinquent, and in this case I am persuaded the inhaler, patent or otherwise, is to blame. The tendency of all true

science is to the simplification of treatment and the methods of practice.

Hoping that this protest will meet with the attention the subject merits, though conscious of how much better a case many another could present,

I remain, yours sincerely,

Orange, Oct. 5th, 1892. G. A. VAN SOMEREN, M.D. Edin.

## THE USE OF ANTISEPTICS IN THE PREVENTION OF SCARLET FEVER AND OF SEPTICÆMIA.

To the Editors of THE LANCET.

SIRS,—The abridged report in the last issue of THE LANCET of my remarks at the Harveian Society on Mr. Tait's paper on Peritonitis is apt to leave an erroneous impression, which I trust you will afford me this opportunity of correcting. Inasmuch as scarlet fever spreads from patient to patient, my experience at the General Lying-in Hospital was, as you state, analogous to that of Mr. Tait in operation cases; but I differ from him *in toto* as to the channel whereby the patients are likely to have received infection, and, consequently, the deductions to be drawn from that experience are entirely at variance with the opinions advanced by him. Mr. Tait relates how, in the days when he used complete Listerian precautions, spray and everything else, he inadvertently carried scarlet fever from one patient to eleven others, on whom he operated in succession; and, assuming that he transmitted the infection at the time of the operation by direct inoculation, he puts this experience forward as evidence against the value of antiseptics to prevent not only scarlet fever but septicæmia also. From this view I entirely dissent, and for the following reason. Scarlet fever, as is generally recognised, spreads through the atmosphere, and the poison obtains entrance to the patient's system through the respiratory passages. It is not necessary, therefore, to assume gratuitously that, because a patient has been operated upon, the poison has of necessity been introduced through the wound. The very fact that three of Mr. Tait's nurses were also infected points the finger in the right direction. On this ground I would submit that antiseptics, however efficiently employed with a view to prevent direct inoculation, would not in themselves prevent infection of the patient by scarlet fever through the ordinary channels, either at the time of the operation or subsequently. On the other hand, if efficiently carried out, they will destroy, and therefore prevent, the introduction of the poison of scarlet fever and of septicæmia through the wound. I have shown how in the General Lying-in Hospital, in which for the last eleven years the service has been conducted upon Listerian principles, though scarlet fever spread from patient to patient, septicæmia as a cause both of illness and of death had been practically eliminated; and though scarlet fever spread, septic processes obtained no hold even in the scarlet fever cases. The precautions adopted aimed at and succeeded in destroying septic matter which might otherwise be carried by direct inoculation through wounds in the genital passage; but these same antiseptic precautions were obviously insufficient, and were never intended, unless supplemented, to prevent the spread of scarlet fever and of other poisons which permeate the atmosphere and find a door of entry through the respiratory passages. This experience I have related in detail in my paper on Scarlet Fever during Pregnancy and in the Puerperal State, published in vol. xxx. of the Obstetrical Transactions.

I am, Sirs, yours faithfully,

Weymouth-street, W., Nov. 23rd, 1892.

ROBERT BOXALL.

## LACTIC ACID IN TUBERCULOUS ULCERATION.

To the Editors of THE LANCET.

SIRS,—The reputation enjoyed by lactic acid as a curative agent in tuberculous ulceration of mucous membranes is well borne out by Dr. Percy Kidd's interesting case reported in THE LANCET of Nov. 19th. That this drug has a curative effect in such cases must be the conviction of all who have employed it persistently and efficiently in laryngeal phthisis. Indeed, even where the laryngeal mischief is extensive and the lungs are affected, we believe that, if accompanied by sufficiently large doses of creosote, it may be applied with advantage either by means of a cotton-wool brush or in the

form of spray, the latter being, however, somewhat choking. Some time ago the probability occurred to us (as it must have to many others) that similar good effects might follow its use in tuberculous ulceration of the skin. Accordingly, without consulting any literature on the subject, we employed it in the following cases, in each of which the concentrated acid was rubbed in vigorously by means of cotton-wool wrapped firmly round a pair of dressing forceps:—

CASE 1.—A patient aged sixty-five was admitted, suffering from tuberculous ulceration of the skin of the right forearm of two years' standing. After scraping, the acid was applied as above, and, in spite of considerable pain, repeated daily for a fortnight. During this period it was noted that a portion of infected tissue had been left behind on which the lactic acid seemed to have no specific effect, and it had ultimately to be removed. It was over two months before cure was effected, and we are not satisfied that the result was any better than that obtainable by ordinary methods.

CASE 2.—A schoolgirl aged twelve was admitted, affected with lupus of the nose, extending also to the mucous membrane. In this case only the cutaneous portion was scraped and the patient made an excellent recovery. It is to be noted that on the mucous membrane the acid apparently exercised its specific effect, a fact which may be contrasted with its failure in the previous case.

CASE 3.—A servant aged seventeen was suffering from tuberculous ulceration covering the greater part of one forearm, of ten years' standing, which had been subjected during this period to various forms of non-operative treatment. After scraping, the concentrated acid was applied and continued for five weeks, when creasote ointment was substituted. This case was encouraging, its progress and the ultimate result being all that could be desired.

CASE 4.—A fireman aged thirty-two was admitted with a patch of tuberculous ulceration the size of the palm of the hand. This was scraped and silver nitrate was applied. Later lactic acid was used, and, although producing marked pain, it was continued, the patient being discharged cured at the end of three weeks. We have heard that there has been recurrence.

CASE 5.—A schoolboy aged ten had extensive tuberculous ulceration of the dorsum of one foot with outlying nodules. This, after scraping, was treated throughout with lactic acid, the application of which was, as in the other cases, accompanied by pain. The patient was in hospital over four months, during which further scraping became necessary, and once more, although a cure was finally obtained, we were unable to detect any special advantage in the use of lactic acid.

The result has been on the whole disappointing, for while it leaves untouched the old dictum that there is but one satisfactory treatment in such cases—a thorough scraping—lactic acid evidences no superiority over caustic potash or chloride of zinc as an after application.

We are, Sirs, yours truly,

W. NEWLANDS CLEMMEY, M.R.C.S.  
JOHN BIERNACKI, M.B. Glas.

Bootle, Nov. 21st, 1892.

## BOYCOTTING IRISH QUALIFICATIONS BY LONDON HOSPITALS.

To the Editors of THE LANCET.

SIRS,—From your report of the last meeting of the Irish Graduates' Association I see that they have set themselves a Titanic task, inasmuch as they hope to get Irish qualifications their legitimate recognition by the governors of London hospitals. The following facts will prove this, being the experience of one who had the audacity to appear before one of these august corporations: In June last your columns contained an advertisement for an assistant surgeon to a large London hospital; for this appointment I was one of several candidates, and in due course appeared before a court of governors of that hospital. To my utter astonishment I was asked by the chairman why I applied for such an appointment, not having obtained the F.R.C.S. Eng. In reply, I stated that there were no such conditions in their advertisement, which led me to believe that monopoly had been done away with by them, as it had been at Hastings and Bristol. This simple statement seemed to stimulate this gentleman to add insult to injury by stating that there was no chance of any surgeon with an "inferior" qualification being admitted to their hospital; that their

tendency was to uphold the higher qualifications, and that if I wished to aspire in the future to one of their appointments, I must obtain the F.R.C.S. Eng., which I suppose is the higher college referred to, but whose new cognomen puzzled me for the nonce. Notwithstanding his provocative speech I suppressed my ire and humbly pointed out that his valuation of my fellowship was not in accordance with that of the Select Committee of the House of Lords, which seemed to surprise him—so much so that he offered to go into my application instanter, which I declined with thanks. Twenty years hence this fossilised condition of affairs will be interred with its guardians; but in the meantime those of us who are capable of, and have an ambition for, hospital work in London cannot hope for any relaxation from these gentlemen, judging from the above experience, which speaks for itself. The only alternative open is, with the help of philanthropic Irishmen, to establish a St. Patrick's Hospital in London, manned by Irish surgeons and physicians, on such a large and generous basis as that we may hope to have for consultants such distinguished Irishmen as Sir Richard Quain and Sir William Mac Cormac, and in the administration and work done in this hospital prove *practically*—"which is all that a generous English public requires"—that we Irish graduates are as worthy of their confidence as English ones, only asking "a fair field and no favour." I am, Sirs, your obedient servant,

ROBERT O'CALLAGHAN, F.R.C.S.I.

Carlow, Nov. 24th, 1892.

## TALIPES EQUINO-VARUS AT THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—The somewhat abrupt conclusion, owing to the lateness of the hour, of the debate on Mr. Edmund Owen's paper at the Royal Medical and Chirurgical Society, when only three Fellows had spoken, must be my excuse for addressing these observations to you. It is not to be denied that in a certain proportion of cases of congenital club-foot relapse does occur after what Mr. Owen calls the orthodox treatment, either from neglect or from faulty growth. Even such cases can, in my experience, all be brought into a good position by subcutaneous tenotomy and myotomy and the use of instruments, but it is not always easy to maintain the improvement. In two such cases at the National Orthopædic Hospital I have performed what is known as Phelps' operation with encouraging results. My father, Dr. W. J. Little, long ago stated as his opinion that congenital club-foot could not be too early operated on. I am glad to hear that Mr. Owen adopts this view. If seen early enough and the after treatment be carefully carried out, even the most severe case may be rectified without even using a Scarpa's shoe or other elaborate appliance. Whether Phelps' operation or tenotomy only be done, the foot must be held in a good position until it has grown into it. Mr. Owen spoke of the pain caused by the "orthodox treatment." No splint or shoe need be applied so as to cause pain or the subsequent formation of sores. A visit to the wards of the National Orthopædic Hospital would convince anyone that the treatment can be carried out without pain. Subcutaneous surgery is one means (as Mr. Hulke pointed out) of maintaining a sepsis, and is surely a simpler and more certain way of doing so than the most rigid antiseptic precautions. Is it, then, an anachronism? Where the one method is inapplicable we need not, thanks to Listerism, hesitate as in former days to make an open wound; but it can never be good surgery to divide any structure needlessly. The foot that has been cured by tenotomy and gradual methods has its functions less impaired than that which has undergone a radical operation involving opening of joints and probable division without hope of repair of the internal plantar nerve; but the latter is obviously a better foot than one in the condition of equinovarus. There are other points of interest raised by Mr. Owen which considerations of space forbid me to touch upon.

I am, Sirs, yours faithfully,

Seymour-street, W., Nov. 23rd, 1892. E. MUIRHEAD LITTLE.

## "CAISSON" WORKING IN BLADDER SURGERY.

To the Editors of THE LANCET.

SIRS,—As I was unfortunately unable to be present at the Medical Society on Monday, Nov. 14th, when Mr. Fenwick read a short paper with the above-mentioned title, perhaps,

you will allow me to add that I have employed an almost exactly similar plan in several instances and fully endorse its applicability to certain cases. The only way in which my operation differed from his was that I have usually sponged out the speculum instead of sucking it dry.

I am, Sirs, yours obediently,

Harley-street, W., Nov. 22nd, 1892.

W. BRUCE CLARKE.

## THE INTERNATIONAL CELEBRATION AT PADUA.

(FROM OUR SPECIAL CORRESPONDENT.)

NOMINALLY to commemorate the tercentenary of Galileo's epoch-making lectures in this august seat of learning, but really to embody the gratitude of modern science for one of the most eventful occasions in its history, the *feste*, which begin on Dec. 6th and conclude on the 8th, have already attracted the interest and in several cases even the actual presence of the votaries of inductive research all the world over. Medicine in particular will be honourably as well as numerously represented at the celebration. She has not forgotten the place that Padua holds in her annals. There it was, to go no farther back, that Fabrizio Acquapendente made the discovery embodied in his treatise, "De Ostiolis Venarum," a discovery which had the most signal effect in enabling his four years' pupil, Harvey, to put his mighty inductions on the irrefragable ground of demonstrated fact and to silence the censorious detraction of would-be vindicators of less worthy claimants. A list, indeed, of the British graduates who left the halls of Padua to diffuse its teaching and its practice throughout Christendom would fill a portly volume, and if that list dwindled down to inanity by the middle of last century it was for the reason that the pupils began to excel the mistress, or at least to transfer her doctrines and methods to other centres of education, scientific and professional. Not that she had ceased to vindicate even then and long afterwards the proud position she had held before and after the Renaissance. With pathologists like Morgagni, and with anatomists like Scarpa, she shed a light on medical teaching and practice whose lustre is hardly dimmed at this day, and if in the struggle for disenthralment from a foreign yoke she had to slacken her zeal for pure science and professional training, she is, now that the goal of a united Italy is attained, making up for the time she sacrificed and the opportunities she had to ignore, and will ere long assume her traditional rôle of leader among the Lombardo-Venetian, and honourable competitor among the Italian universities.

Preparatory to the detailed account of the proceedings, which I will send next week, I can now, through the courtesy of the organising committee, present an outline of their tenour. The Minister of Public Instruction will represent the Government at the celebration—Signor Ferdinando Martini. On the 5th there will be a reception, on the part of the Paduan students, of the students of other universities, and of those of the other institutions for the higher professional instruction throughout the peninsula. Delegates from British and other seats of learning or medical schools will also be warmly welcomed and hospitably entertained. On the evening of that day a grand choral festival will inaugurate the reception in the Sala della Ragione. On the 6th the Senatus Academicus and subordinate staff will receive the delegates of other institutes and cities, who will thereafter be presented to the civic authorities of Padua. This will be followed by a visit to the various monuments and points of historic or academic interest within the walls and neighbourhood. The University Rifle Brigade will hold a competitive trial of skill by shooting at the target, and the day will close with a grand festival, in which the students will act as hosts, in the Sala della Ragione. The 7th will be memorable for the commemoration of Galileo in the academic Aula Magna, on which occasion will be presented the *gon-falono* (standard) wrought by the ladies of Padua for the University. This will be followed by the speeches of the day, delivered by the Rector, Professor Ferrari, and by the Commendatore, Professor A. Favaro, after which will be unveiled the commemorative tablet, duly inscribed for the occasion. A "Spettacolo di gala" will be given

in the evening at the Verdi Theatre. On the 8th a *cortège* consisting of all the students attending the academic and other educational institutions of the city, and of the civic authorities and the other guilds and corporations, will patrol the city, to lay crowns on the monument of Galileo in the Piazza Vittorio Emanuele. After this a grand fencing tournament will be held by the students, to be followed by a reception given by the Town Council of Padua. The day and the proceedings as a whole will be concluded by a great festival of the students in the Sala della Ragione.

The arrangements, already in progress for some weeks, promise a most successful celebration, of which my next letter will give an extended report.

Padua, Nov. 28th, 1892.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

### *The Jaffray Hospital.*

THE 28th of November was the seventh anniversary of the opening of this hospital by the Prince of Wales. A concert and fireworks testified to the event, after which cheers were given for the founder, who was unavoidably absent.

### *A Temporary Terror.*

Some of the officials of the General Hospital were lately thrown into a state of alarm by the escape of a small patient aged eleven. This precocious boy, who was under massage treatment for an injured arm, was heard to object strongly to the process, and to declare that he would drown himself. One night, during the brief absence of the nurse on duty, he disappeared. The canal was dragged, the telephone set to work, and for some hours no tidings of the fugitive could be ascertained. Meantime he had run nearly three miles in his night-shirt and slippers to the house of a relative. The question of responsibility was thus considerably lessened, and the institution resumed its ordinary routine.

### *Death from Football.*

A fatal accident from the effects of a kick during a football match on Nov. 27th was the cause of an inquest at Worcester. The Rev. G. H. Knight, one of the assistant masters at Bromsgrove College, during the game was accidentally kicked by an opponent. He subsequently complained of his head; a doctor was called in, who thought that he would be better after a night's rest. On the following morning he was found dead in bed. The necropsy showed a large clot of blood from a ruptured vessel upon the brain. Unfortunately these accidents are not infrequent, and the manner in which the game is often played gives opportunities for injury which may lead to disastrous results; but the risks seem only to stimulate the players and to heighten the interest of onlookers.

Nov. 30th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *Natural History Society of Newcastle.*

A LEGACY of £2000 has been received by the hon. treasurer of the Natural History Society from the executors of the late Mr. John Coppin of Bingley, Northumberland, who had bequeathed this sum towards the maintenance of an efficient curator for the museum of the Society.

### *A New Scientific Society.*

A new scientific society has been formed in Newcastle, having for its object the pursuit of certain branches of microscopical research, some of which have been comparatively neglected. By the regulations every member is expected to devote himself to a particular line of investigation and to mount as many slides illustrative of his work as will enable him to give one to each of his colleagues on the occasion of the monthly meeting. It has been a common complaint at our microscopical meetings that the members do so little microscopical work.

### *Gateshead.*

The medical staff of the Gateshead Children's Hospital have presented a report to the committee on the overcrowded state of the wards. The hospital was commenced on a very modest scale, but such is its utility that it was very soon

filices, and must ere long be very considerably enlarged. There should be no difficulty in doing this in a large and prosperous town like Gateshead. The Gateshead guardians, like others, have agreed to grant certain quantities of tobacco and snuff to deserving inmates of the workhouse, and I hear that this humane decision has given much satisfaction to the rate-payers.

*The late Dr. Heath of Newcastle.*

I have seen a very fine portrait of the late Dr. Heath as President of the Durham College of Medicine in the gallery of Messrs. Mawson, Swan and Morgan, of this city. It has been painted by Mr. C. Kay Robertson after the fine and well-known picture by Mr. G. W. Joy. It shows Dr. Heath in his D.C.L. robes, and it has been inspected by numerous members of the profession. There is also shown in the same gallery (published by special permission of the executors) a very fine autotype reproduction of the original picture by Mr. Joy. Those who wish to obtain copies of it should apply early, as the issue is limited and it is not published for profit.

*Death of a distinguished Colonial Surgeon.*

Mr. Daniel Robertson died last week at his son's residence in Gateshead. The deceased occupied many important positions. In 1864 he was appointed surgeon of McCarthy's Island, Gambia, on the West Coast of Africa. Previously he was Colonial Surgeon of Bathurst and Colonial Secretary in 1848; he also served as Queen's Advocate and Judge of the Court of Common Pleas, and acted some time as Governor of the same place; but his most distinguished service was when he volunteered his services as surgeon on board H.M.S. *Curlen*, the surgeon, nearly all the officers, and two-thirds of the crew having died of yellow fever.

*Cumberland.*

The water-supply of Penrith has occupied the consideration of the local board of health, and much correspondence has passed between the board and Mr. G. F. Deacon, the engineer of the proposed waterworks, and Dr. Stevenson, of Guy's Hospital, who concludes his report as to the surrounding waters by pointing out "that the difficulty felt in determining what scheme to adopt was simply an embarrassment arising out of the riches about Penrith in the matter of the water-supply." The cost of the schemes, he further said, was low in relation to the quantity and quality of the water, and, whichever was ultimately adopted, he felt satisfied that Penrith would be in the possession of one of the best supplies in the kingdom.

*Death of the Cumberland Centenarian.*

The death of the Cumberland centenarian, Mr. Thomas Moffat, is announced at the advanced age of 102 years, 3 months and six days. He was originally a weaver, and his apprentice indentures, dated Aug. 3rd, 1802, are still preserved and attest his great age. Up to a couple of years ago Mr. Moffat had uninterrupted good health. The deceased was interred at Wigton.

Newcastle-on-Tyne, Dec. 1st.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Entries at the Dublin Medical Schools.*

THE entries for the anatomical classes for the session, according to the official returns, are as follows:—

Trinity College	181
Royal College of Surgeons	178
Catholic University	116
Total	475

As compared with last year there is an increase of 1 in the Catholic University, a decrease of 28 in the College of Surgeons' School, and a decrease of 50 in Trinity College. As regards the last-named institution there is no first-year's class owing to recent rule. This makes a decrease of 77 in the three schools as compared with the returns in 1891, which to some extent may be explained by the five years' curriculum coming into operation on Jan. 1st last. Going back as far as 1889 I find that the total entries that year were 635, showing that in three years the numbers have diminished by no less than 160, or about one-fourth of the total.

*Dublin University Biological Association.*

The opening meeting of the Association was held in Trinity

College last week, presided over by Dr. Macan. Dr. Beatty, president, delivered an address on the subject of the Functions of the Glands of the Skin. He stated in the course of his observations that he had made exhaustive experiments on numerous animals and arrived at the conclusion that he could not accept Dr. Unna's theory in reference to the sweat glands. A vote of thanks was passed to the lecturer for his address.

*Transactions of the Royal Academy of Medicine.*

The tenth volume of the Transactions of the Academy has now been issued to the Fellows. In the Section of Medicine there is an excellent paper by Dr. W. G. Smith on Recent Advances in the Etiology of Diseases of the Skin and their bearing upon Treatment; while Dr. Tweedy has, in a paper on the Diagnosis and Treatment of Diseases of the Stomach, described the instrument devised by Dr. Einhorn of New York, and which he has styled a "stomach bucket." There are papers on the Treatment of Typhoid Fever, by Drs. Boyd and Beatty; and a Case of Typhoid Relapse, by Dr. J. Moore. In the Section of Obstetrics there are Notes of a Case of Ruptured Uterus (recovery), by Dr. P. J. Barry; and an interesting communication by Dr. Atthill, on Dilatation of the Uterus, and the Treatment of some of the Commoner Forms of Uterine Disease. Dr. Cosgrave, in the Section of State Medicine, discusses the Control of Inebriates; and Mr. Flinn has a communication on Some Modern Methods of Sewage Treatment. There are other papers which I hope to refer to on another occasion.

*Cork Hospital Saturday.*

By additional subscriptions this fund has reached a total of £853, and this was allocated last week to various Cork charities, nearly half the entire amount being divided between the North and South Cork Infirmaries. Last year it may be mentioned the fund came to £600.

*Royal College of Surgeons.*

The Fellowship has been obtained by the following—viz., D. P. Coady (Naas); C. J. Lyons (British Honduras); and F. T. Newell (Dublin).

*The late Mr. William Colles, F.R.C.S.I.*

The many friends of the late Mr. Colles will be glad to learn that the medical profession are having a memorial portrait painted by Mr. W. Osborne, to be placed in the board room of the Royal College of Surgeons, Dublin. Subscriptions, limited to one guinea, should be forwarded to the Honorary Treasurer, Colles' Memorial, Royal College of Surgeons, Dublin.

*Belfast Board of Guardians: Resignation of Medical Officers.*

We are at present in the throes of a stiff medical contest in Belfast owing to the resignation of two of the medical officers of the Belfast Workhouse, which took place on Nov. 29th. One of these—Dr. Seaton Reid, the father of the medical profession in Belfast—is now in his eighty-sixth year, and has been an officer in the Poor-law service for forty-six years. Dr. Reid, who was formerly Professor of Materia Medica at Queen's College, held the office of physician to the Belfast Fever Hospital (which is under the Poor-law Board), and from the great experience which he acquired there obtained a very high reputation as a consultant in fevers and in all acute diseases. The second medical officer, who resigned on the same day—Dr. Brice Smyth—was visiting medical officer to the Union Hospital, and had charge of the Maternity. He has been for thirty years an officer of the Board of Guardians. Both these appointments are worth £150 per annum, and there is a keen competition for them, the following being candidates:—Dr. E. C. Bigger, Mr. Hall, Dr. McCullagh, and Dr. Killen. At the Board of Guardians meeting on Nov. 29th the services of Dr. Reid and Dr. Smyth were spoken of in the highest terms, and it was decided to grant them a superannuation allowance to be finally settled at a future meeting.

*Queen's College, Belfast.*

I understand that the Lord-Lieutenant has written, through his secretary, to the President of Queen's College, expressing his strong approval of the proposed students' union, and intimating his intention of subscribing £25 to the fund.

*The Belfast Charitable Society.*

At the annual meeting of the Belfast Charitable Society, held on Nov. 29th, Dr. Richard Purdon, visiting physician, in his medical report which was submitted, refers among other matters to the severe visitation of influenza at the

institution towards the end of last year, which caused fifteen deaths—a not unnatural result considering the great age of the old people in the charity, and that many of them were affected with chronic ailments of the chest, heart &c. In February of this year a complete change in the nursing arrangements was made, and this has already brought about an improvement in the cleanliness, comfort and health of the patients. The dietary has also been improved, a greater variety of food being given. Dr. Purdon states that there is much want of additional accommodation for the sick and infirm patients, at least six extra beds in each of the male and female infirm and hospital wards being required.

#### *Delfast Nurses' Home and Training School.*

The annual meeting of this deserving medical institution was held on Friday, Nov. 25th, the Countess of Shaftesbury presiding, when a very satisfactory report was presented, and special thanks were given to Dr. Calwell, Dr. Stafford Smith and Professor Sinclair for their services at the home.

Mr. David Turner has been presented by the patients and nursing staff of the Royal Hospital for Incurables with an illuminated address and a gold watch on the occasion of his retirement from the post of resident medical officer to that institution.

At Waterford Petty Sessions Mrs. Poole was fined £5 for compounding a medical prescription, not being entitled to do so. Nov. 30th.

(FROM OUR OWN CORRESPONDENT.)

#### *A Singular Medico-legal Case.*

At a recent meeting of the Société de Médecine Légale an interesting communication was made, on behalf of Professor Cazeneuve, on a singular case of infanticide involving a somewhat unusual medico-legal problem. It was a question concerning an infant of five months which had died suddenly in 1891 without showing any previous symptoms of disease. At this time there was no suspicion of crime, and it was only owing to certain rumours, sixteen months later, that the police took action and caused the body to be exhumed. The chemical analysis for traces of arsenic, lead, mercury and other poisons came to nothing. However, further research led to the discovery of eight small pieces of an elastic blackish-grey substance blocking up the intestinal tract. After repeated washings and careful examination these were recognised as portions of sponge, and M. Cazeneuve was of the opinion that the ingestion of these fragments of sponge was the cause of death. In support of this opinion he cited the custom which obtains in certain country districts of killing stray dogs and predatory cats by placing in their way small pieces of sponge soaked in grease, which, upon being swallowed by the animals, become swollen in the intestinal canal, after the manner of a sponge tent and thus induce fatal obstruction. Founding an opinion on these considerations, and also taking into account the fact that the portions of sponge presented a well-defined cut surface, the medical jurist concluded that circumstantial evidence was established that the child was caused to swallow the pieces of sponge in a vehicle such as milk or soup. The jury also took this view, with the result that the accused was sentenced to penal servitude for life.

#### *Poisoning of a Prison Physician.*

A curious but luckily not fatal poisoning accident recently befell the medical officer of Beauvais prison. It appears that for some time the prisoners suffered from some inexplicable malaise, and suspecting the pharmaceutical extract of walnut leaves, which it seems is the practice to add to the prison drinking water, the medical officer, instead of having recourse to experiment on the lower animals, resolved to try the diluted extract upon himself, with the result that he almost sacrificed his life. About five minutes after taking the mixture he experienced a sense of great heat at the epigastrium, extreme dryness of the throat, dimness of vision and weakness in the limbs. Poisoning was at once suspected and energetic remedies adopted, with the result that in three days he was able to resume duty and to open an inquiry into the cause of his misfortune. It was then found that the druggist who had the prison contract for the supply of drugs, had, through a mistake on the part of his pupil, sent extract of belladonna for extract of walnut leaves. The druggist was hereupon indicted before the Correctional Tribunal of Beauvais, condemned to prison for six days and fined 100 francs.

#### *Hysteria after Ovariectomy.*

M. Debove, at a recent meeting of the Medical Society, recorded the case of a patient aged thirty-eight who had the uterine appendages, including both ovaries, removed in 1889. The result was in every way satisfactory from an operative point of view. In June, 1890, however, the patient had an hysterical attack for the first time, followed by several subsequent attacks. Her medical history previously to the operation contained no record of any hysteria. When examined by M. Debove there was well-marked hemi-anæsthesia, with "ovarian" pain on pressure, the latter exciting a fresh attack. The iliac pain, moreover, was readily transposed by a magnet. The point, however, that the communication was intended to emphasise was that the ovariectomy did not prevent the occurrence of hysteria or even of the manifestations generally known as "ovarian."

#### *The Medical Practitioner and the Concierge.*

Medical men on your side of the Channel hardly realise what their *confrères* on this side have to contend with. In England a man reckons, it is said, his home his castle; in France he has to reckon first with his *concierge* or hall porter. A case illustrating this is recorded by a Montpellier paper. A medical man having changed his address, his former *concierge* persistently refused to give his new address to the patients who came to request it. An appeal to the landlord, whose servant the *concierge* alone is, not mending matters, our *confrère* summoned them both before the local tribunal. Here it was elicited that the amiable janitor, aggrieved on the usual grounds, made answer to all inquiries for the doctor—"Unknown," "Gone without leaving address" &c. The court very properly held that such behaviour was fraught with prejudice to our *confrère's* interests, and fined the *concierge* and landlord £40 with costs.

Paris, Nov. 30th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

#### *Professor Leyden on Professor Pettenkofer's Experiment.*

In the Society for Internal Medicine Professor Leyden alluded to Professor Pettenkofer's experiment last Monday. He attached great importance to it. He thinks that the strict adherents of the bacteriological theory are too dogmatic and one-sided. The measures taken against cholera had been one-sided too, aimed as they were mainly at the destruction of cholera bacilli. In this endeavour people had gone so far as to regard cholera patients mainly as media of cholera contagion. Such patients and even persons suspected of being such patients had had their personal rights quite inhumanly interfered with. Professor Leyden reminded his hearers that something similar had taken place in the case of tuberculous patients after the discovery of the tubercle bacillus in 1882.

#### *The Cholera Epidemic in Russian Poland.*

The Prussian Commissioner for the basin of the Vistula published on the 23rd inst. the following statistics of the cholera epidemic in Russian Poland. In three days the Government district of Radom had 24 cases and 8 deaths, Lublin 14 and 12, Siedlec 42 and 30, and Lomza 16 and 4.

#### *Scientific Publications.*

The 157th number of the "Collection of Scientific Lectures," edited by Rudolf Virchow and Wilhelm Wattenbach, contains an essay by Robert Franceschini of Vienna entitled "Biology as an Independent Science." Dr. Behring has published a book entitled "The Therapeutic Serum of Tetanus and its Application to Patients."

Berlin, Nov. 28th.

**MEDICAL MAGISTRATE.**—Thomas J. Henry, L.R.C.P., L.R.C.S. Edin., Government Medical Officer for the district of Warialda, New South Wales, has been placed on the Commission of the Peace for the colony of New South Wales.

**UNIVERSITY OF CAMBRIDGE.**—The first part of the third examination for degrees of M.B. and B.C. will be held on Dec. 13th, 14th, 16th, 17th and 19th; the second part on Dec. 13th, 14th, 15th, 16th, 17th, 19th and 20th. The examination for the degree of M.C. is fixed for the 16th, 17th and 19th inst.

## Obituary.

WM. LINDOW DICKINSON, L.R.C.P.LOND., M.R.C.S., J.P.

By the death on Nov. 20th of Mr. Wm. Lindow Dickinson, in his seventy-third year, there is severed not only from the town of Workington but also from a very large surrounding district a medical connexion which has been preserved in unbroken succession for nearly a century. Beginning practice in Workington about the early years of the present century, Mr. Dickinson's grandfather laid the foundations of a practice which extended wellnigh through the whole west of Cumberland, and which was recruited from time to time, first by Mr. Dickinson's father and uncle, and later by the introduction of the late Mr. Peat, who was associated with the deceased gentleman till some fifteen years ago, when Mr. Peat died and Mr. Wm. Lindow Dickinson retired in a great measure from active practice. In these days of railways, telegraphs, telephones &c., it is no easy matter to thoroughly estimate the great difficulties or the vast amount of hard work which the carrying on of such a practice entailed, but the high estimation in which those services were held by such a large section of the community was in itself convincing testimony of the conscientious way in which these duties were performed and the high professional skill which was at command. In this work, up to the time of his retirement, the deceased gentleman took a large and active part, bringing to bear upon the practice of his profession a mind singularly well informed, an experience ripened by his early training and a judgment at once accurate and keen. It was to these qualities, combined with a personal charm of manner, that Mr. Dickinson owed much of his success; and it is not at all astonishing that he succeeded in gaining from his patients a confidence and esteem such as it is given few men to enjoy. Nor, with all the work which came to his hands, did he neglect to keep himself thoroughly well read in all the current medical literature of the day. The study of physiology especially found for him great and absorbing interest—an interest which he maintained till the day of his death. It was doubtless to the meditative and thoughtful mind which the pursuit of this study brought to Mr. Dickinson that the medical world is indebted for the honour which belongs to him of having been the first person to diagnose trichinosis in the living subject in England. The whole matter was fully dealt with by Dr. Spencer Cobbold in the Cantor Lectures delivered in April, 1871, when the services which Mr. Dickinson had rendered to science were fully recognised. He was a typical specimen of the old family practitioner, courteous, cautious, dignified and refined, beloved by his patients and of a kind and generous nature, which tended to make his presence in the sick room particularly pleasing. In his relations with his fellow practitioners, while ready at all times to place his long experience and skill at their disposal, he yet closely adhered to the best traditions of the profession, and would never allow his name to be associated with anything that was not consistent with the strict rules of high professional practice. Until a few days before his death he had been in his usual health. On the evening on which he died he had just finished tea when he was seized with an attack of angina pectoris and passed away almost before his sorrowing family could come to his assistance. Mr. Dickinson was buried at St. John's, Workington, the funeral being attended by a large number of friends and professional brethren; and not a few of the old townspeople with whom he had so long been associated felt as they stood at the grave that they had lost in the person of Mr. Dickinson one who through life had shared much of their sorrow and who had always been to them friend and counsellor of no ordinary kind.

MICHAEL FOX, L.A.H., L.M.

WE regret to have to announce the death of Mr. Michael Fox, which occurred at Claycross, Chesterfield, on Nov. 6th, from enteritis. The deceased was well known and esteemed amongst the teachers and students of Dublin, with whom he was an especial favourite. He practised in Longford for some time, and while there he gained the admiration of numerous patients and friends; but through ill health he was obliged to relinquish his practice and travel. He took voyages to India, Australia, and to North and South America. Believing he had sufficiently recovered, he again

settled down to practice, but it proved too much for him. He was only thirty-three years of age, and was one of three brothers belonging to the medical profession.

## Medical News.

**HUMANITARIAN LEAGUE.**—A meeting of members and friends of the Humanitarian League will be held at the Wheatsheaf Restaurant, 13, Rathbone-place, Oxford-street, W., on Monday, Dec. 5th, at 8 P.M., to urge the need of abolishing private slaughterhouses and of substituting public abattoirs under direct municipal control. Dr. B. W. Richardson will take the chair, and an address will be given by Mr. H. F. Lester, Honorary Secretary of the London Model Abattoir Society.

**MR. HUBERT M. WOOD**, who has for some time past held the post of senior resident medical officer at the Royal National Hospital for Consumption, Ventnor, was on Nov. 15th presented by the staff, patients and employes of the institution, with a handsome illuminated address and valuable carriage clock, on the occasion of his resignation, as a recognition of the sincere regard in which they held him and of the deep regret they felt at his departure. Dr. Cyril Lewis, the new resident medical officer, made the presentation.

**FOOTBALL CASUALTIES.**—During a match at Aldershot between the Medical Staff Corps and the Northampton Regiment, on Nov. 19th, a private of the A Company, Northampton Regiment, fractured his leg and was admitted to the Cambridge Hospital.—A young man of Crewe playing in a match at Nantwich on Nov. 23rd, received severe internal injuries, and lies in a precarious state in that town.—On Saturday, Nov. 26th, whilst playing at Worcester for the Bromsgrove Rugby Club against Worcester, a player received injuries from which he died on the following day.—Also on Saturday last the captain of the Liverpool Caledonians, in the course of a Lancashire League match against South Shore, at Blackpool, sustained a compound fracture of the leg and was admitted to the Northern Hospital, Liverpool.—A youth aged sixteen died at the Haileybury College, Hertford, on Saturday last, from internal injuries received in a game on the previous Thursday.

**THE NATIONAL DENTAL HOSPITAL.**—The annual dinner of the staff and the past and present students of this hospital and college was held on Nov. 25th at the Holborn Restaurant. Sir James Crichton-Browne presided, and was supported by many distinguished members of the dental profession and others. In proposing "Success to the National Dental Hospital and College" the chairman said no one could venture to predict what degree of development odontological science would reach in the course of a few decades. It was advancing in public estimation year by year; and a qualified dentist ought to have a seat on the General Medical Council. For the rapid development of dentistry the profession was greatly indebted to Dr. Cunningham, who had shown how necessary it is that an examination of the teeth of school children should be made from time to time. Mr. Roughton and Mr. Harry Rose replied to the chairman's address, and after other toasts had been proposed and responded to, the meeting separated.

**VOLUNTEER MEDICAL STAFF CORPS.**—The annual competition for the Challenge Shield took place on Saturday, Nov. 26th, at the Head Quarters, 1st Middlesex Rifle Volunteers. Nos. 1, 2 and 4 companies competed. The judges were Surgeon-Major A. E. Hayes, D.S.O., secretary to the Surgeon-General at the Royal Victoria Hospital, Netley, and Surgeon-Captain Pope, the Netley adjutant. Surgeon-Major Hayes declared No. 1 company, commanded by Surgeon-Captain Valentine Matthews, to be the winners. He said that the way in which the different competing companies went through the various movements in company and stretcher drill, showed great credit both to officers and men of the corps, and it also showed that the adjutant and instructor must have worked hard to bring men up to such a high state of efficiency. All the companies drilled remarkably well, but he had never seen such perfect drill as that of No. 1, the winning company; they all moved as one man, and there was not a single mistake. Surgeon-Colonel A. J. Norton and the officers of the corps entertained the judges at mess at the Holborn Restaurant in the evening. The commandant, Surgeon-Colonel A. J. Norton, the adjutant, and all the officers were present at the competition, together with a number of friends.

## Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ANDREW, F. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Hendon Local Board.

CONNOR, D., L.R.C.S. L.M.Irel., has been appointed Government Resident Medical Officer and Public Vaccinator for the District of Victoria Plains, Western Australia.

COSENS, W. B., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Surgeon to the Taunton and Somerset Hospital, vice Liddon.

DEANE, JOHN E. J., L.R.C.P. Irel., L.F.P.S. Glasg., has been appointed Health Officer for Rutherglen, Victoria, Australia.

ELOOE, W., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer at the Colonial Hospital, Perth, Western Australia, and Assistant to the Superintendent of Vaccinations, vice Sloman, resigned.

ESLER, A. W., M.D., M.Ch. Irel., has been appointed Health Officer for McIvorshire, Victoria, Australia.

FLEMING, ALEX. A., L.F.P.S. Glasg., has been appointed Public Vaccinator for the District of Otago, New Zealand.

FLEMING, H. H., M.B., B.Ch. Dub., has been appointed Public Vaccinator for St. Arnaud, Victoria, Australia.

GARDNER, HAROLD, Mr., has been appointed House Surgeon to Charing-cross Hospital.

HOUSE, F. M., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer and Public Vaccinator at Katanning, Western Australia.

LATIMER, H. A., M.R.C.S., has been appointed Senior Surgeon to the Swansea General Hospital, vice Thomas, retired.

LAWSON, G. L. L., M.R.C.P. D.P.H. Edin., M.R.C.S., has been appointed Government Medical Officer and Vaccinator for the District of Brisbane Water, New South Wales.

LONGDEN, F. R., L.R.C.P., L.R.C.S. Edin., has been appointed Health Officer for Buninyong, Victoria, Australia.

LYS, HENRY GRABHAM, M.D. Lond., M.R.C.S., has been appointed Medical Officer for Out-patients to the Royal Victoria Hospital, Bournemouth.

MCCARTHY, HENRY, L.R.C.S., L.M. Irel., has been appointed Health Officer for the District of Tatura, Victoria, Australia.

MUIR, ROBT. D., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to Charing-cross Hospital.

PENNY, H. JAS., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Health Officer for Port Fairy, Victoria, Australia.

FOTTS, WALTER A. B., M.R.C.S., has been appointed Public Vaccinator for Harrow, Victoria, Australia, and Health Officer for Kowroshire, E. R., Victoria.

PULLIN, F. B., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Health Officer for Flinders and Kangerong Shires, Victoria, Australia.

RANSOME, H. F., L.R.C.P., M.R.C.S., has been appointed Honorary Assistant Medical Officer to the Manchester Hospital for Consumption and Diseases of the Throat.

REED, HENRY A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for Hamilton, Tasmania.

REID, GEO. M., M.D. Edin., L.R.C.P. Lond., M.R.C.S., has been appointed Health Officer for Mount Alexandershire, Victoria, Australia.

REID, GEO. MARR, M.B., M.S. Abord., has been appointed Public Vaccinator for Cobden, Victoria, Australia, vice Ewing, resigned.

ROBERTS, SIDNEY JOHN, L.R.C.P. Lond., M.R.C.S., has been appointed one of the Resident Surgeons to the Birmingham General Dispensary.

COLLASON, A., L.R.C.P. Lond., M.R.C.S., has been appointed Health Officer for Tempostowe Shire, Victoria, Australia.

SECCOMB, S. H., M.R.C.S., has been appointed Public Vaccinator for the District of Ivanhoe, New South Wales.

SHELLS, W. F. M., L.R.C.P. Lond., M.R.C.S., has been appointed Government Medical Officer and Vaccinator for the District of Hillgrove, New South Wales.

TEICHELHANN, E., L.R.C.P. Irel., F.R.C.S. Eng., has been appointed Assistant Health Officer at Port Adelaide, South Australia.

THOMAS, J. T., L.R.C.P. Irel., L.R.C.S. Edin., has been appointed Medical Officer for the Mungo Sanitary District of the Newport (M.M.) Union.

TURNER, J. A., M.B., C.M. Edin., has been reappointed Medical Officer of Health for the Combined Sanitary Districts of Leicester and Rutland.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index.)

BELOVALE HOSPITAL FOR CHILDREN, 70, Gloucester-street, S.W.—House Surgeon. Board, lodging, fuel and light found.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with apartments and board.

BOOTLE BOROUGH HOSPITAL.—Assistant House Surgeon and Dispenser. Salary £40 per annum, with board, lodging, and washing.

BRECON INFIRMARY.—Resident House Surgeon, unmarried, and also to undertake Dispensing. Salary £70 per annum, with furnished apartments, board, attendance, fire and gas.

EDMONTON UNION.—Medical Officer for the district of Winchmore-hill. Salary £25 per annum, and 20 per cent. thereon in lieu of payment for expensive medicines, with extra fees (in Midwifery 10s. per case) prescribed by the Orders of the Local Government Board. (Apply to Mr. F. Shelton, the Clerk, 806, High-road, Tottenham.)

FARRINGTON GENERAL DISPENSARY, Bartlett's-buildings, Holborn-circus, E.C.—Resident Medical Officer. Salary £100 per annum, with apartments and attendance.

FISHERTON ASYLUM, Sallsbury.—Assistant Medical Officer. Salary £100 per annum, with board, lodging and washing.

HOLBORN UNION.—Assistant Medical Officer at the Infirmary, Archway-road, Upper Holloway, N. Salary £100 per annum, with board, lodging and washing. (Apply to the Clerk to the Guardians, Clerks' Offices, Clerkenwell-road, E.C.)

HOSPITAL FOR WOMEN (THE LONDON SCHOOL OF GYNÆCOLOGY), Soho-square, W.—Clinical Assistants.

NOBLE'S ISLE OF MAN AND GENERAL HOSPITAL AND DISPENSARY, Douglas, Isle of Man.—Resident House Surgeon; unmarried. Salary £100 per year, with apartments, gas, coal and laundry free.

NORTHUMBERLAND COUNTY LUNATIC ASYLUM.—Assistant Medical Officer in the asylum, unmarried. Salary £120 per annum, increasing £10 a year up to £160, with furnished apartments, board and lodging.

OWENS COLLEGE, Manchester.—Junior Demonstratorship in Physiology and Histology. Annual salary £100.

ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £150, with furnished apartments, fire, light and attendance.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—Senior House Surgeon. Salary, with board and residence, £75 per annum.

ST. ANDREW'S UNIVERSITY, UNIVERSITY COLLEGE, Dundee.—Demonstratorship of Anatomy. Salary £120 per annum.

STOCKPORT INFIRMARY.—House Surgeon. Salary £100 per annum, with board and apartments.

## Births, Marriages and Deaths.

### BIRTHS.

EADES.—On Nov. 20th, at Carr-street, Ipswich, the wife of S. O. Eades, L.R.C.P., of a son.

EMERSON.—On Nov. 12th, at Cloringbold, Broadstairs, the wife of Dr. P. H. Emerson of a daughter.

EMMETT.—On Nov. 26th, at Woodville, Kingston-road, Portsmouth, the wife of Richard Emmett, M.R.C.S., L.R.C.P. Lond., of a son.

EVIL.—On Oct. 8th, at Broken Hill, New South Wales, the wife of Frederick Claude Evil, M.R.C.S., of a son.

JACKSON.—On Nov. 25th, at Carrington, Wootton-gardens, Bournemouth, the wife of Basil Jackson, M.R.C.S., L.R.C.P., of a daughter.

JARDINE.—On Nov. 28th, at Lichfield-gardens, Richmond, Surrey, the wife of James Jardine, M.B., of a son.

MILWARD.—On Nov. 23rd, at Agra, the wife of Surgeon-Major Milward, of a daughter.

SUTTON.—On Oct. 19th, at Beenleigh, Queensland, the wife of Mr. Alfred Sutton, J.P., of a son.

TATHAM.—On Nov. 24th, at Halesowen, Worcestershire, the wife of Ernest J. Tatham, M.D. Cantab., of a son.

### MARRIAGES.

FLANAGAN—LOFTIE.—On Nov. 17th, at St. Mary's, Cadogan-street, Terence Woulfe Flanagan, M.B. &c., third son of the late Right Hon. Stephen Woulfe Flanagan, of Fitzwilliam-place, Dublin, to Margaret Hester Wentworth, only daughter of the Rev. William J. Loftie, of Sheffield-terrace, Kensington.

HILLIER—FULLER.—On Nov. 30th, at High Garrett, by the father of the bride, T. Ernest Hillier, M.A., M.B. (Cantab.), Paddington Infirmary, son of the late Thomas Hillier, M.D. Lond., F.R.C.E., to M. Burnett Fuller, daughter of Robert H. Fuller, M.A., High Garrett, Braintree.

WHEELER—BUSHE.—On Nov. 24th, at St. Jude's Church, Southsea, by the Rev. F. W. B. Dunno, LL.D., Rector of West Thorney, uncle of the bride, assisted by the Rev. J. Blake, Vicar of the Parish, Humphry J. Wheeler, M.D., youngest son of Thos. Wheeler, Esq., J.P., of High Wycombe, to Emmeline Alice Augusta, eldest daughter of George D. Bushe, Esq., of Wilton, Bray, Ireland.

WILLIAMS—PASCOE.—On Nov. 17th, at Kanyon Chapel, Solon-road, Brixton, S.W., John W. Williams, L.R.C.P., of New-cross-gate, to Eleanor Philippa, youngest daughter of the late Thomas P. Pascoe, Esq., of Camberwell.

### DEATHS.

FRANKLIN-LOYD.—On Nov. 25th, at Reigate, T. Franklin-Lloyd, M.R.C.S., L.S.A., aged 47.

HILL.—On Nov. 22nd, suddenly, at St. Holler's, Jersey, Surgeon-Lieut. Colonel Henry Walter Hill, Bengal Army, aged 42.

LAY.—On Nov. 21st, at Cairo, Surgeon-Major Peter Goodall Lay, Bengal Army (Retired).

PALMER.—On Nov. 24th, at his residence in Great Yarmouth, Frederick Palmer, F.R.C.S., in his 80th year.

ROBERTSON.—On Nov. 24th, at Granville House, ateshead-on-Tyne, the residence of his son, Daniel Robertson, L.R.C.S. Edin., late Colonial Secretary and Acting Governor of H.M.'s Settlement, Bathurst, West Coast of Africa, aged 79.

SHEPARD.—On Nov. 27th, 1892, at Ty Cernel, Usk, Mon., Alexander John Shepard, M.R.C.S. Eng., L.S.A., aged 77.

TAYLOR.—On Nov. 24th, at 202, Earl's Court-road, South Kensington, Michael Waistell Taylor, M.D., F.S.A., late of Hutton Hall, Penrith, in his 69th year. (Friends are requested to accept this the only intimation.)

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths.

# Medical Diary for the ensuing Week.

Monday, December 5.

**KING'S COLLEGE HOSPITAL.**—Operations, 2 P.M.; Fridays and Saturdays, at the same hour.  
**ST. BARTHOLOMEW'S HOSPITAL.**—Operations, 1.30 P.M.; and on Tuesday, Wednesday, Friday, and Saturday at the same hour.  
**ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.**—Operations, daily at 10 A.M.  
**ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.**—Operations, 1.30 P.M.; and each day at the same hour.  
**CHELSEA HOSPITAL FOR WOMEN.**—Operations, 2 P.M.; Thursday, 2 P.M.  
**HOSPITAL FOR WOMEN, SOHO-SQUARE.**—Operations, 2 P.M.; and on Thursday at the same hour.  
**METROPOLITAN FREE HOSPITAL.**—Operations, 2 P.M.  
**ROYAL ORTHOPÆDIC HOSPITAL.**—Operations, 2 P.M.  
**CENTRAL LONDON OPHTHALMIC HOSPITAL.**—Operations, 2 P.M., and each day in the week at the same hour.  
**UNIVERSITY COLLEGE HOSPITAL.**—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M. Eye Department, 2 P.M.  
**CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road).**—5 P.M. Mr. Lennox Browne: Rhinitis, Acute, Purulent, Croupous, Hypertrophic, Hyperæsthetic (Hay Fever and Hay Asthma), Atrophic; Deformities and Deviations of the Nasal Septum.  
**THROAT HOSPITAL (Golden-sq.).**—5 P.M. Dr. Greville MacDonald: Laryngitis, Acute and Chronic.  
**MEDICAL SOCIETY OF LONDON.**—8.30 P.M. Surgeon-Colonel J. B. Hamilton: Cholera, its Epidemic Progression and Causation.

Tuesday, December 6.

**GUY'S HOSPITAL.**—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.  
**ST. THOMAS'S HOSPITAL.**—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

## Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*  
*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale and advertising departments of THE LANCET to be addressed "To the Publisher."*  
*We cannot undertake to return MSS. not used.*

COMMUNICATIONS relating to the EDITORIAL business of THE LANCET must in every case be addressed exclusively "To the Editors," and not to them otherwise than in their official capacity.

*Inquirer.*—Will our correspondent say whether there is a wage limit in his dispensary; and whether it is one of the metropolitan provident-dispensaries or an independent institution; also how many medical officers there are?

A SILLY PREJUDICE.

To the Editors of THE LANCET.

SIRS.—A short time ago I was called to see a child aged two years, whom I was told was dying fast. I arrived in about thirty minutes and found the child collapsed, pulse almost imperceptible, and suffering from convulsive spasm of diaphragm. History of diarrhoea and vomiting for three days, with administration of an apple and a pint of cold milk during some slight temporary improvement on the previous day. I saw at once that the child had under present conditions about two hours to live, owing to the acute irritation which was the cause of the convulsion. So I adopted a remedy advocated by many authorities and often successfully used by myself—viz., hypodermic injection of morphia, of which I gave one-tenth of a grain. The child then slept for three hours, during which the breathing was quite easy and colour natural. After this, however, the convulsions returned, recurring about every five minutes, and despite every effort the child died asphyxiated. Owing to the injection of morphia having excited some prejudice among the uneducated class to whom the child belonged the father, I believe, expressed some dissatisfaction at the treatment, and, an officious policeman stepping in, an inquest was ordered, to find out whether the child died of morphia poisoning. This is the point about which I wish to express my strongest feeling on behalf of the profession. Surely such an annoyance, if often repeated, would paralyse medical men when called to any case *in extremis*; and although the unanimous verdict of the jury gave the cause of death according to my certificate, such an action is likely to prejudice many minds against one of the most valuable remedies in the hands of the profession, besides having been altogether frivolous and unnecessary.—Your obedient servant,  
 November, 1892.

E. C. S.

## EXPERIMENTS ON LIVING ANIMALS.

*The Editor of the "Verulam Review."*—With much of what our correspondent writes us we are entirely in sympathy, and it may be observed that almost the whole of the suggested conditions—at least, such as are at all practicable—are at present carried out. The Home Secretary may, whenever he thinks fit, call upon an experimenter to give an accurate report of all experiments done by him; and, as a matter of fact, the inspector calls for reports or inspects the records at frequent intervals. The nature of each experiment, with operation involved, is most carefully defined by the Home Secretary on every licence given, and printed forms are supplied gratis to each holder of a licence, and on these all experiments must be carefully and accurately entered together with the kind of animal experimented on and the date on which the experiment is performed. As regards anaesthetics, we may point out that the amount of the anaesthetic used could not possibly give any indication as to the depth of the anaesthesia induced or of the time during which this anaesthesia was maintained. We are therefore of the opinion that the conditions required to be conformed to by the Home Secretary form a really very comprehensive and efficient safeguard against cruelty, and along with those made compulsory by the inspector are fully as stringent and wide reaching as those suggested by our correspondent.

*Africanus asks*—“Will any gentleman who has recently passed the examination for the M.D. Durham for practitioners kindly give a brother medical man living in a colony some idea of the text-books necessary for reading for the examination, length of time required for reading, nature of practical examination in hospital and also of the extent of the *vivâ-voce* requirements?”

*Alpha*—The fees are quite reasonable, and especially those for the London journeys. It is desirable that the charge for medicines should be as low as their cost price and the trouble of dispensing warrant. Practically this is the case in our correspondent's system.

## A MODE OF PRESERVING VACCINE LYMPH.

To the Editors of THE LANCET.

SIRS,—Perhaps you may find room in THE LANCET, for the benefit of your readers, for the following formula for preserved vaccine lymph, which I have used for one year with satisfactory results. Vaccine lymph, five minims, best glycerine and distilled water, of each five minims. For the lymph select a healthy child with four plump vesicles, puncture without drawing blood, and transfer to minim measure with capillary tube; then add preservative and mix. The lymph, by the admixture, appears to clear at once and become bright-like sample enclosed, and preserved in April of this year. Adventitious particles rise to the surface in gelatinous nodules and are easily removed. Lymph so preserved retains its fluidity and ensures absorption. I treat all vaccine lymph in this way before using it, and with generally good results. It produces good plump vesicles and less tendency to premature areola. I have not had a miss since I have used it. For the distilled water hold a tumbler over the steaming spout of a kettle and a sufficiency is soon obtained. A convenient way of mixing the preservative is to take a drachm stoppered bottle with spout and divide into half-drachms with small phial; then put into it half a drachm of distilled water and half a drachm of glycerine, and mix. Then transfer lymph to Husbands's capillary tubes; fill from two-thirds to three-fourths. These tubes are to be preferred on account of their quality, shape and length. They fill easily and require less heat to fuse them. A tube put into the lymph in the minim measure takes up sufficient for a charge for four vesicles. I generally use Rose's S-needle, circular-point scarificator, which requires rotating once upon the selected places. I have just received fourth grant for successful vaccination.—I am, Sirs, yours obediently,

JAMES TILLY, M.D. St. And.,

Public Vaccinator (two districts), Brentford Union.

Nov. 20th, 1892.

*First Aid to the Injured*.—We can recommend the following as being reliable and sufficient for ordinary readers requiring information on this subject:—Osborn's First Aid Ambulance Lectures, arranged according to the St. John Ambulance course of instruction; Roberts's Illustrated Lectures on Ambulance Work. There is also a book by Surgeon-Major Martin.

*L.R.C.P. Lond., M.R.C.S.E.*—We can see no objection to our correspondent allowing himself to be so nominated under the circumstances.

## INTRA-THORACIC AUSCULTATION.

To the Editors of THE LANCET.

SIRS,—It has been my habit for some time, whenever I have suspected œsophageal stricture or gastric dilatation, to try to elucidate the case by auscultating over the accessible gastric area while directing the patient to drink a glass of water. I fancy it has furnished me with valuable confirmatory evidence, especially in cases of dilatation.

I am, Sirs, yours faithfully,

Nico, Nov. 21st, 1892. A. W. GILCHRIST, M.D., M.R.C.S., L.R.C.P.

## ST. MICHAEL IN THE AZORES AS A HEALTH RESORT.

In a lengthy communication an esteemed correspondent calls attention to the benefit he has derived from a sojourn in St. Michael, whither he went to escape the so-called diarrhoea which had been prevalent in Madeira. The journey to the former island is described as most beautiful and the scenery picturesque in the highest degree. There are many boiling springs in St. Michael, supplying hot baths of both sulphur and iron, which have excellent curative powers. The Government of Portugal has established a large building containing sixty separate bath-rooms, which are free to all comers. Here the late Mr. John Hilton enjoyed two or three years of peaceful rest before his return to and demise in this country. The climate of the Azorean Group in general is most equable, the mean average temperature for the year being rather over 60° F.; as a consequence tropical vegetation abounds and fruits and flowers are seen and enjoyed all the year round. All the parks and gardens of the landed proprietors of St. Michael are stated to be open to visitors and the public generally. The cost of living is small, and travelling about the island is cheap. Altogether the statement of our correspondent would go to show that some classes of invalids would act wisely in selecting St. Michael as a resort during the winter months.

*Sewell*.—Our correspondent's supposition is very improbable. We do not see how an “unsuspecting operator” could mistake an artificially distended bladder for a “sacculated” viscus. Moreover, the question of mechanical obstruction by an enlarged prostate could easily be verified by examination. When once a coroner has decided to hold an inquest, upon information received, the corpse is in his possession, and he has the power of imposing a fine and committing for contempt any person tampering with such cadaver. If the body has been buried, it is customary to place the matter before the Home Secretary, with a request for an order for exhumation.

*A Country Doctor*.—Probably the system our correspondent mentions is the most convenient and suitable for the purpose. But it need not be expensive. The automatic arrangement in the system referred to may obviously be dispensed with, as the earth merely thrown by hand on the excreta in the pail beneath would give equally effectual results. The quantity of dry earth needed each time is about 1 lb. (rich garden mould is the best). Slop water should be disposed of by irrigation, or run directly off into a flowing ditch or other suitable channel.

## “THE EMPLOYMENT OF COCAINE.”

To the Editors of THE LANCET.

SIRS,—With regard to the question propounded by “Young Practitioner” in the last number of THE LANCET, I am justified, I think, in saying that the use of cocaine in the conjunctival affections of children is unattended by danger. At the Ophthalmic School belonging to the parishes of St. Saviour and the City of London, an institution for the retention and treatment of children suffering from eye disorders, we constantly employ solutions of cocaine varying in strength from 2 to 4 per cent., and in many instances we apply the salt itself to the conjunctiva of the lids. Such applications are made daily to the eyes of many children, often for months or years, in order to minimise as far as possible the discomfort attendant on the use of strong remedies. We have never observed bad results from cocaine thus applied to children. It may be well to emphasise the fact that cocaine itself, while freely soluble in vaseline or castor oil, is not very soluble in water (1 in about 1000). Hydrochlorate of cocaine, on the other hand, is soluble in less than half its weight of water, and is on this account generally used in the preparation of aqueous solutions. In conclusion, let me remind “Young Practitioner” that cocaine must not be used to the exclusion of those remedies without which full justice can be done to no case of ophthalmia.

I am, Sirs, yours faithfully,

Welbeck-street, W., Nov. 28th, 1892.

SYDNEY STEPHENSON.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Hockmondwike Reporter, Yorkshire Post, Dorset Standard, Law Journal, Ilalstead Gazette, Islington Gazette, Newmarket Journal, Bath Gazette, Pembroke County Guardian, Scottish Leader, Sussex News, Mining Journal, Surrey Advertiser, Windsor and Eton Gazette, West Middlesex Standard, Scotsman, Journal of Commerce (Liverpool), Weekly Free Press and Aberdeen Herald, Hertfordshire Mercury, Local Government Chronicle, Windsor and Eton Express, Leeds Mercury, Reading Mercury, Liverpool Daily Post, Bristol Mercury, Insurance Record, West Middlesex Advertiser, West Australian (Perth), Argus (Melbourne), Lincolnshire Chronicle, Torquay Times, Australian Medical Journal, Kentish Mercury, West London Observer, Sunday Times, Oban Times, Australian Medical Gazette, Le Temps (Paris), Wigan Examiner, Staffordshire Sentinel, Builder, Devizes Gazette, Athlone Times, Architect, Keighley News, Bolton Weekly Guardian, Carlisle Express, Times of India, Norfolk Daily Standard, Surrey Times, Pioneer Mail, Hereford Times, Northampton Daily Reporter.*

Lectures  
ON THE  
PHYSIOLOGY AND PATHOLOGY OF  
BLOOD DESTRUCTION.

Delivered in the Examination Hall, Victoria Embankment,  
on Nov. 22nd & 29th, 1892,

By WILLIAM HUNTER, M.D. EDIN.,  
M.R.C.P. LOND. &c.,

ASSISTANT PHYSICIAN TO THE LONDON FEVER HOSPITAL; LATE  
SANITARY RESEARCH SCHOLAR, GROCERS' COMPANY.

LECTURE II.

II. SEATS OF HÆMOLYSIS.

GENTLEMEN,—In my first lecture I showed that the destructive change which takes place in the blood is not of the slow nature hitherto described, but is of an altogether more acute character; and, moreover, that this acute hæmolytic is an event of daily occurrence. We have now to consider where this destruction takes place. Does it occur throughout the blood generally or is it localised to certain organs of the body?

One organ at once suggests itself as the probable seat of such a process, and is indeed generally so regarded—namely, the liver. Are not the bile pigments formed by the liver, and are they not in turn derived from hæmoglobin? Is not the liver the chief seat of deposit of blood pigment in large quantities in certain diseases—e.g., pernicious anæmia—in which everything points to a great destruction of blood? Is it not also, as the experiments show, the seat of deposit of pigment when an increased destruction of blood has been experimentally brought about? Where more likely than within the liver has this destruction taken place?

Next to the liver the spleen suggests itself—if, indeed, it does not do so before. Is not blood pigment in greater or less amount a very frequent constituent of the splenic tissue, and is not the peculiar structure of this organ, along with the peculiarities of its circulation,<sup>1</sup> specially favourable to the destruction of effete corpuscles and their subsequent conversion into pigment?

On these points observers are by no means agreed. The exact rôle of the liver and spleen in hæmolytic has long been a *quæstio vexata*. The requisite data for deciding the matter one way or another have hitherto been wanting. With regard, for instance, to the significance of blood pigment in this relation the greatest differences of opinion exist. How far does the presence of pigment in the liver and spleen, whether in health, in disease, or as the result of experiment, indicate these organs as the seat of the previous destruction of blood. In the case of the liver may it not simply be due to a destruction of hæmoglobin conveyed to it from elsewhere? In the case of the spleen may not the pigment be the result of capillary extravasations of blood arising from the delicacy of the splenic tissue, as von Wittich suggests; or the result of the "scavenging" (as distinguished from any hæmolytic) function of that organ, in virtue of which all kinds of effete pigment particles are to be found in it? To these questions some very definite answers are supplied by the present investigation.

DISTRIBUTION OF BLOOD PIGMENT AMONGST  
THE ORGANS.

First of all I will direct your attention to certain peculiarities in the distribution of blood pigment amongst the three organs we have seen to be chiefly concerned in its disposal—viz., the liver, spleen and marrow. This distribution is by no means uniform. The liver, for example, is sometimes loaded with pigment while none is to be found in the spleen, while conversely the spleen may contain much pigment to the entire exclusion of the liver. The following are the chief variations in this respect I have found in the course of my observations.

1. After transfusion of blood (Experiments 1-16) the spleen

usually contains a very large amount of blood pigment, while the liver may contain not only relatively but absolutely little. The contrast between the two organs is indeed very striking. The healthier the animal after the transfusion the more striking is it. Moreover, in rabbits what little pigment is present in the liver is always in the form of minute granules within the liver cells, whereas much of the pigment within the spleen is in large conglomerate heaps. Little or no pigment is to be found within the capillaries.

2. As regards the bone marrow the conditions favouring the presence of pigment in it are usually the same as in the case of the spleen, the character of the pigment in both cases being also the same (Experiments 5, 25 and 27). In both cases the amount is greatest when the destruction has been slow and gradual, and little or none may be found when the destruction is rapid (Experiments 42, 44, 46, 47, 48, 55, 61, 65, 74, 76, 77, 83 and 84). It is only in a comparatively few cases that a distinct excess of pigment is to be found in the bone marrow when destruction is very rapid (Experiments 43, 58, 63 and 75). A very close relation thus exists, according to my observations, between spleen and red marrow as regards the relative amounts of pigment to be found in each. The relation is, however, not absolutely constant. I have never found an increase in pigment in the marrow without a corresponding, and even larger, increase in the spleen. On the other hand, I have not unfrequently found a large excess of pigment in the spleen when there was none in the marrow (Experiments 9 and 16 after transfusion; 61, 85, 86 and 87 after injection of hæmolytic agents). The closeness of the relationship in function between spleen and marrow is manifested in other and more striking ways. After removal of the spleen I have always found exceedingly well-marked structural changes in the red marrow, developed too with great rapidity (Experiments 64, 68 and 81).

3. The liver sometimes contains a large amount of pigment when not a trace is to be found in the spleen. This is strikingly seen in the sections now shown from cases of pernicious anæmia. The great disproportion between the amounts of pigment in these two organs in this disease I have fully brought out elsewhere.<sup>2</sup> I have there shown from the recorded analyses that while in health and in other diseases the average percentage of iron in spleen and liver is 0.171 and 0.083 respectively—the percentage being almost twice as great in the spleen as in the liver,—in pernicious anæmia there is a sevenfold increase in this percentage in the liver, with little or no increase in the spleen. Some of the analyses are—0.091 for the spleen and 0.614 for the liver (Stabel), and 0.227 for the spleen and 0.518 for the liver (Rosenstein). In one of my own cases I found on analysis 0.310 per cent. of iron in the liver, while the spleen, examined micro-chemically, showed hardly a trace of iron. In an old person who died of bronchitis I found a percentage of 0.0924 of iron in the liver. A similar distribution of blood pigment between liver and spleen can, I find, occasionally be induced experimentally (Experiments 42 and 43) by the action of hæmolytic agents. In the sections now shown you will note the large amount of fine pigment within the liver, confined to the liver cells, while the spleen shows comparatively little.

BLOOD PIGMENT AS AN INDEX OF THE SEAT OF  
HÆMOLYSIS.

Liver.

How far, then, are we to regard the presence of blood pigment in the spleen and liver as an indication of their relative activity in hæmolytic? Does the large excess of pigment in the spleen after transfusion, while little or none is to be found in the liver, point to the spleen as the organ chiefly concerned in destroying the foreign red corpuscles? Does the even larger excess in the liver in pernicious anæmia, while little or none is to be found in the spleen, indicate that the liver, as distinguished from the spleen, has been the chief seat of the preceding hæmolytic?

As the result of my earlier investigations, the answer I gave to both these questions was in the affirmative. For not otherwise could I account for the remarkable variations in the distribution of the pigment in the two cases. In a thesis on the subject presented to the University of Edinburgh in 1886 I drew as the result of my investigations a sharp distinction between the action of the liver and spleen as hæmolytic organs. In the liver the destruction, I concluded, was effected in some special way by the liver cells, the chief result of the destruction being the formation of bile pigments

<sup>1</sup> The arteries open directly into open mesh network of channels devoid of definite walls, from which the veins take direct origin. The interstices of this meshwork are filled with a delicate lymphoid tissue in which the various cellular elements lie embedded (von Wittich, Die Milz: Hermann's Handbuch der Physiologie, Bd. vii., 345).  
No. 3615.

and probably also of urea (Noel Paton). Within the spleen, on the other hand (or to a less extent within the bone marrow), the hæmolytic was of a different character, resembling more that which occurs around extravasations, the chief result of it being the reduction of hæmoglobin to the form of albuminates of iron. I concluded that an even balance was maintained in health between the activity of the liver and spleen, any disturbance of this relation on the part of the liver being followed by much more serious consequences than when the spleen was at fault, for the reason that the destructive process within the liver was of a much more active nature than that in the spleen. I showed grounds on this view for regarding pernicious anæmia as essentially a disease of the liver resulting from the morbid activity of that organ in hæmolytic. "The nature of the morbid action on its part, which brings about such a destruction of red corpuscles, it is of course not easy to determine. But since in other glands there are from time to time evidences of perverted activity, as shown by altered or excessive secretion, so also in the liver in pernicious anæmia it is probable that some change either in quantity or quality of its secretion is accountable for the enormous destruction of corpuscles. Confirmation of this view as to the pathology of pernicious anæmia can only be obtained after examination of the various organs in a great number of cases" (p. 215).

Such was the view I held regarding the significance of blood pigment, and in particular regarding the importance of the liver as a hæmolytic organ, at the outset of the present investigation. It is well to have it thus fully before us, if only for the reason that the present investigation of which it formed the working hypothesis has afforded no support to it, especially as regards the liver. For the results of that investigation show that the amount of blood pigment in the spleen or liver is no criterion whatever of their relative activity in hæmolytic. This is especially the case where that pigment lies within the liver cells. Pigment in this situation I find to be merely an evidence that hæmoglobin has been broken up within the liver cells without affording any clue as to where it has been set free, whether in the circulation generally in another organ, e.g., the spleen, or in the capillaries of the liver itself.

Thus the difference between spleen and liver already noted in Experiments 42 and 43 was by no means so marked in the fresh, as it now appears in the hardened tissue. In both cases the fresh spleen when tested with sulphide of ammonium revealed a very large amount of pigment, much of it in diffuse form. It is clear, then, that a good deal of this has been lost in the process of hardening, so that I cannot too much impress on you that the activity of an organ in hæmolytic cannot be correctly gauged by the amount of blood pigment found in it after hardening. Nor can it be gauged, I find, by the amount found in the fresh condition. For in two cases of pernicious anæmia, in which the liver contained a very large amount of pigment, while the spleen gave very little iron reaction, the latter was obviously the chief seat of active change in the blood. It was much swollen, purplish in colour (contrasting with the absolute pallor of all the other organs) and contained much free hæmoglobin. It is clear, then, that blood pigment as a guide to the seat of hæmolytic has but a limited significance. The information derivable from a study of the distribution of blood pigment is not always, however, of the negative character just indicated in the case of the liver. In the case of the spleen and bone marrow it is of a more positive kind, as I will now proceed to show.

#### *Spleen.*

First of all let me say that my observations supply no support whatever to the view that the presence of pigment within the splenic pulp in the conditions in which it is found so abundantly is referable in any way to the occurrence of capillary extravasations of blood. If such were the case, it ought to be specially abundant in the chronically congested spleen of cardiac or hepatic disease. I have found, on the contrary, that such spleens are frequently singularly free from blood pigment.

Moreover, they lend no support to the view that blood pigment, when present, merely collects in the spleen in virtue of the scavenging function of the cells of that organ.

You will see from the sections now shown (Experiments 33 and 34) that after injection of carmine or ultramarine blue into the blood the pigment particles are to be found in large masses within the capillaries of the liver, chiefly in the portal capillaries, while not a twentieth or even a fiftieth part of the quantity is to be found in the spleen.

So far as mere scavenging function towards inert particles is concerned the liver, according to my observations, is a far more important organ than the spleen; and this applies, I find, not only to such extraneous particles introduced into the blood, but also to stromata and other remains of red corpuscles formed by the action of distilled water within the blood (Experiments 88 and 188 [a]). After its injection in large quantity, the number of colourless granules and spherules (stromata) to be found in the spleen was both absolutely and relatively small, while in the capillaries of the liver they were in extraordinary abundance. As regards inert particles circulating in the blood, the conditions therefore favour more their arrest in the capillaries of the liver than in the spleen.

I have shown you that as regards blood pigment the reverse is often the case. After transfusion, for example, large quantities may be found within the spleen, while little or none is present within the liver, and what little is present may be solely confined to the liver cells, and absent from the capillaries.

According to Quincke the manner of death of red corpuscles after transfusion is that they gradually lose their elasticity, become effete, are taken up by leucocytes, and ultimately deposited within the capillaries of the liver and in the spleen. If such a description were a correct one, the rôle of the spleen would be a comparatively passive one, the spleen would merely be the depository of the pigment conveyed to it.

I conclude from the presence of much pigment in the spleen when none is to be found in the capillaries of the liver that the description given by Quincke does not represent what actually takes place; and that the rôle of the spleen in removing red corpuscles from the circulation is not the relatively subordinate one thus ascribed to it. This conclusion has, moreover, an experimental basis; for some experiments I made in this relation show that the cells of the spleen have the power of arresting red corpuscles before these latter have undergone sufficient change to allow their enclosure by ordinary leucocytes (Experiments 92, 93 and 94). The experiments were of this kind, that blood from the ear was examined and compared with that obtained by direct puncture of the exposed spleen. An incision was made directly over the spleen for this purpose. Control observations showed that mere exposure of the organ in this way for several hours did not appreciably affect either its size or the character of the blood obtainable by puncture from it. On the other hand, if pyrogallic acid were injected into the blood, then either immediately (Experiment 94) or within three minutes (Experiment 93), according to largeness of dose, a great enlargement of the spleen occurred, amounting, it might be, to a fourfold or fivefold increase. The spleen, at the same time, became excessively turgid, and its former red colour was replaced by a dark venous one, the position of the Malpighian bodies being, however, still marked out as red points. As early as fifteen minutes after such an injection well-marked changes were observable in blood withdrawn from the spleen, especially in the red corpuscles, while the blood of the ear at the same time showed nothing abnormal; and fifteen minutes later these altered red corpuscles were found enclosed within large splenic cells of pulp. After death in four or five hours, numerous changes in the blood, including many large cells filled with but slightly altered red corpuscles, were found in the spleen, while absent from the liver or from the blood elsewhere.

It seems to me clear, then, that the rôle of the splenic cells towards the injured red corpuscles is no mere scavenging one, since in that case similar cells enclosing red corpuscles would have been found in the liver. It is much more active. This becomes most manifest when through any cause—e.g., transfusion, or action of certain poisons—the red corpuscles have received any injury short of their complete disintegration. The injured corpuscles are seized on in great numbers by the cells of the spleen long before a single one can be found within the leucocytes. After death the chief and sometimes the exclusive seat of such cells is the spleen, few or none being found within the liver (Experiments 54, 58 and 75). The activity of the spleen in withdrawing red corpuscles from the circulation is thus, I conclude, decidedly greater than the whole body of leucocytes, including those within the liver. Were the spleen not present, red corpuscles in process of becoming effete would remain longer in the circulation than they actually do. It is in virtue of this function that the spleen may become the seat of much pigment, when—e.g., after transfusion—the liver may be free. To a certain, albeit

a limited, extent therefore the presence of blood pigment within the spleen is an indication of a special hæmolytic activity of that organ.

#### Bone Marrow.

A similar line of reasoning, without however the same experimental basis, leads to the conclusion that the pigment found within the bone marrow is an indication of an action of its cells in withdrawing red corpuscles from the blood analogous to, though much less marked than that of the splenic cells. I conclude that it acts to a certain extent as supplementary to the spleen. It is, according to my experiments, structurally, and presumably therefore also functionally, more affected by removal of the spleen than any other tissue of the body (Experiments 62, 64 and 89). The change in some cases amounts to a complete transformation, the marrow tissue being replaced by a mass of larger lymphoid cells closely packed together. Moreover, after removal of the spleen the changes found in the marrow after injection of hæmolytic agents are more marked than those met with when the spleen is present.

The information to be obtained from a study of blood pigment regarding the probable seats of hæmolysis, although not unimportant, is thus comparatively limited. So far as it goes it is chiefly negative, pointing to some organ other than the liver as the chief seat of hæmolytic change—in the case of the red corpuscles, most probably the spleen. Much more definite in character was the information I got from a study of the morphological changes in the blood during active hæmolysis, particularly from a study of their distribution.

#### MORPHOLOGICAL CHANGES IN THE BLOOD DURING ACTIVE HÆMOLYSIS.

The changes I refer to involve the plasma, the red corpuscles and the leucocytes. The chief of these are as follows:—

1. The presence of *colourless albuminous granules and spherules* of varying size, products of disintegration of plasma and red corpuscles, the smallest of them closely resembling the bodies variously termed by observers "hæmatoblasts" of Hayem, "blood plates" of Bizzozero, "granule bodies" (*Körnchenbildungen*) of Max Schultze, "elementary bodies" (*Elementarkörperchen*) of Zimmermann. They are derived, according to my observations, partly from the red corpuscles, the protoplasmic stroma of which can be seen oozing out in droplets and floating away free in the form of small spherules, partly and very largely from the plasma itself. A large number of them I therefore regard as albuminous precipitates (granules) thrown down from the plasma. The leucocytes, so far as my observations go, are an altogether secondary and unimportant source of such granules. The relation between these products of disintegration and the hæmatoblasts and blood plates regarded by Hayem and Bizzozero respectively as normal elements of the blood and by the former as the precursors of the red corpuscles has been to me a subject of much interest throughout my investigations; and it is one I would willingly discuss here did time permit. I will content myself with merely stating that the only difference I have been able to note between the granules I have described and blood plates is that the latter have seemed always to me to be more highly refractile than the former. As to the relation of these blood plates to blood formation, a subject on which Hayem expresses himself with so much assurance, I venture to think that the question is still an entirely open one. I have totally failed to satisfy myself of the existence of any such relationship.

2. Small *coloured spherules* derived from the red corpuscles, partly by a process of oozing in the way just described, but more frequently and characteristically by what I have for convenience termed throughout by observations, a process of budding. The red corpuscle is seen to become constricted at some part, forming a small bud identical in depth of colour and appearance with the chief mass of the corpuscle, and the two portions may frequently be seen for a time united by a delicate, colourless process. This change in the red corpuscle I learnt to recognise as one very characteristic of blood undergoing destructive change. I never found it in healthy blood. In no way can it be better studied than by gradually warming blood to a temperature of 45° or 50° C., as Max Schultze first showed. Under certain circumstances the whole red corpuscles may thus break up, forming a number of highly coloured spherules.

3. *Stromata*, decolourised red corpuscles, the framework of the red corpuscles freed from hæmoglobin, best studied after injection of distilled water into the blood; albuminous

spheres, usually colourless, sometimes retaining a little of their hæmoglobin, homogeneous throughout, without obvious envelope.

4. These stromata are to be sharply distinguished from *Schatten*. They are small vesicles consisting of an outer envelope enclosing a fluid and usually two or three exceedingly minute particles of indistinct character. They are derived from red corpuscles, and the envelope is usually regarded, but incorrectly, as that of the red corpuscle. It is, I believe, an artificial product, resulting from a chemical change in the extreme outer portion of the red corpuscle. I have never found it in the blood in health; it is not a product of normal hæmolysis. For its production a degree of acidity of blood is necessary such as is never found as the result of natural disease, and can only be formed by the action of certain destructive agents. The bodies I describe are not to be found in the blood after injection of distilled water, while stromata and colourless spherules are in abundance. They are frequently found, however, in great numbers after the injection of destructive agents such as pyrogallic acid and toluylendiamine, more especially the former.

It was from a study of the distribution of these changes in different organs and portions of the circulation during active hæmolysis induced by these agents that I gained most information regarding both the nature and the seats of hæmolysis.

#### ACTION OF POISONS.

The substance whose action proved most interesting was toluylendiamine. Like pyrogallic acid, although in a different way and in a different degree, it exercises a well-marked destructive action on the blood. The chief point of interest connected with it is that, unlike pyrogallic acid, its action differs greatly in different animals. It is exceedingly destructive and poisonous in cats, even in small doses—a dose of even 0.15 gramme killing a cat in the course of a few hours with intense hæmoglobinuria. It is less so in dogs, such a dose causing jaundice without hæmoglobinuria; and it is least of all so in rabbits, causing neither jaundice nor hæmoglobinuria even in large doses. In many of my experiments doses as large as one gramme were injected directly into the blood of rabbits with comparatively little effect. The action of this substance on rabbits differs indeed so strikingly from its action on dogs and cats, that Stadelmann, who first studied it, confessed himself utterly unable to account for it, and his observations were therefore exclusively confined to the latter animals. The reason that induced him to reject rabbits was the reason that induced me to make use of them; for the object of my experiments was not to induce a marked destruction of blood, such as is produced in dogs and cats by even small doses of this drug, but to simulate more closely the process which goes on in health. To cause a degree of change in the blood capable of inducing hæmoglobinuria or jaundice was not my purpose, but rather to induce such a slight exaggeration of the process of hæmolysis as would render recognisable evidences of hæmolysis usually hidden or obscure. This object I could not have attained with destructive agents like pyrogallic acid, glycerine or distilled water, for, as I afterwards found, their destructive action differs totally in its character from anything that takes place in health, and that is the case even with the smallest doses. With toluylendiamine, on the other hand, I found myself able to produce all the evidences of an increased hæmolysis without the slightest disturbance of the animals' health, and without the occurrence of any changes (e.g., jaundice, hæmoglobinuria &c.) not usually found attending that process in health. When the dose was small these evidences included slight changes in the blood such as are found in health, with increased formation of bile pigments, and increased deposit of blood pigment either in the liver, spleen, or bone marrow. With larger doses still more marked changes were induced, including in addition to the foregoing some never found in health—viz., appearance of large numbers of stromata and *schatten* in the blood, and of remains of hæmoglobin in the urine (not hæmoglobinuria). By varying the dose I was thus able in the rabbit to induce the most varying degree of destruction in a manner quite impossible in the dog or cat, where the substance has a poisonous action independent of its destructive action on the blood. Since all my information regarding the seats of hæmolysis, as well as the probable nature of this process in health, was obtained from a study of this drug, I will first record the chief facts I have elicited with regard to its action.

## THE SPLEEN THE CHIEF SEAT OF ACTIVE HÆMOLYSIS.

1. After small doses the morphological changes indicative of hæmolytic are confined solely to the spleen, and are absent from the blood elsewhere, even from that within the liver.

Experiment 80, rabbit; 0.25 gramme of toluylendiamine per kilo of weight injected intravenously; killed two days later. Numerous changes—colourless granules and spherules in great numbers, and budding of red corpuscles—in spleen and blood of splenic vein; blood of portal system elsewhere perfectly normal.

2. After a medium dose the changes extend to the blood within the liver, but are still absent from general circulation, both during life and after death.

Experiment 61, rabbit; 0.66 gramme toluylendiamine per kilo injected intravenously. Killed on following day. No change in blood of ear during life, either in plasma or in corpuscles. Well-marked changes in plasma and red corpuscles in spleen and splenic vein, also in liver, but none in hepatic veins issuing from liver, or in blood of inferior vena cava. Large amount of iron in spleen, none in liver. Similar distribution of changes in Experiment 75.

3. With still larger doses the changes extend to the general mass of the blood, but are always most marked in the portal blood, and especially in the spleen.

Experiment 82, rabbit; 0.8 gramme toluylendiamine per kilo. Death in sixteen hours. Great majority of red corpuscles in spleen and splenic vein converted into *Schatten*; only a few normal corpuscles left. In blood of mesenteric veins only a few *Schatten*; majority of corpuscles normal. In hepatic vein *Schatten* still fewer in number; and in inferior vena cava below the liver *Schatten* exceedingly few in number. Spleen gives an excessively deep iron reaction; liver a very slight one. A similar distribution was observed in Experiments 65 and 90 (cat) and 78 (rabbit).

In all cases, then, the greatest degree of change was found in the blood of the portal as distinguished from the general circulation, and especially in the spleen and the splenic vein. Had the changes been always found in the liver as well as within the spleen, one might have referred their presence in these situations to the scavenging function which we have seen is performed by these two organs. As I have shown, however, the stromata and other remains of red corpuscles, after injection of distilled water, are found in greatest abundance in the liver in the foregoing cases. On the other hand, the distribution of the changes was reversed, the spleen being the chief and sometimes the exclusive seat of the various products of disintegration. The greater number and variety of the evidences of hæmolytic in the spleen, as compared with those in the liver or in the blood elsewhere, seemed to point to that organ as the seat of an active hæmolytic.

## EFFECT OF REMOVAL OF THE SPLEEN.

To ascertain to what extent the spleen was the seat of an active hæmolytic or how far, on the other hand, it acted merely as a scavenging organ collecting from the blood the various debris circulating in it, I made a series of experiments similar to those already described, having previously excised the spleen.

This operation was exceedingly well borne by the animals; it appeared, indeed, to affect them but little. In my earlier experiments I waited for a day or two after the excision before injecting the drug. Later on, when I found that the operation itself was without any ill effect, I was in the habit of injecting the drug immediately after the spleen was excised. The results of the experiments under these circumstances appear to me all the more remarkable. I illustrated the action of toluylendiamine in the healthy animal by three experiments, in which the doses were respectively 0.25, 0.66 and 0.8 gramme per kilo of weight, doses which I may for convenience term small, medium and large.

1. After removal of the spleen the destructive action of toluylendiamine on the blood of rabbits, both in small and medium doses, is completely abolished, in large doses is much diminished.

Experiment 68, rabbit; spleen excised; 0.6 gramme toluylendiamine per kilo injected into blood; killed three days later. Absolutely unaffected during life. No changes found in blood either during life or after death. No remains of hæmoglobin in urine. No reaction of iron either in liver or bone-marrow.

Experiment 69, rabbit; spleen excised; 0.75 gramme toluylendiamine per kilo injected into blood. Killed on following day. Absolutely no change of any kind in blood either of portal or general circulation, or in liver. Liver gives no iron reaction. Urine free from hæmoglobin or its pigment remains.

The effect of removal of the spleen in lessening hæmolytic is evidenced in other ways.

2. The nutrition is less affected by toluylendiamine in the spleenless than that in the normal animal.

Thus a dose of 0.66 gramme per kilo in the healthy animal caused a loss of body weight of 150 grammes in two days (Experiment 61); while a dose of 0.66 gramme per kilo followed by one of 1 gramme per kilo five days later in a spleenless rabbit of the same brood caused only a loss of 50 grammes (Experiment 60). Almost three times the dose had caused a third of the loss of weight and that, too, notwithstanding that the animal had been subjected to a somewhat severe operation. Even more striking perhaps was the contrast afforded by other two experiments, in which a total of 0.33 gramme per kilo caused in the healthy animal a loss of weight of 170 grammes (Experiment 43); while the spleenless one, notwithstanding its operation, actually put on 200 grammes of weight in the same period of time, after more than twice the dose—namely, 0.84 gramme per kilo.

In all cases the conditions as to food and drink were alike. In the group of experiments in the healthy animal the dose of toluylendiamine varied from 0.13 to 0.8 gramme per kilo, the average of seventeen observations being 0.36 gramme per kilo. In the spleenless animal the average dose in eight observations was 0.64, ranging from 0.28 to as much as 1 gramme per kilo. Nevertheless, all the characteristic effects of toluylendiamine as a hæmolytic agent, whether as regards changes in blood, in urine, in organs, or in body weight and nutrition, were much more frequently and more strikingly manifested in the healthy animal. In the spleenless one, as has been seen, they were frequently absent.

3. The removal of the spleen lessens the formation of bile pigment. Doses of toluylendiamine, which in the normal animal cause an increased flow of bile and an increased formation of bile pigment, are now without effect (Experiments 69 and 81, in spleenless animals, twenty-four and forty-eight hours, after doses of 0.75 and 0.8 gramme per kilo respectively; no evidence of polycholia; while in Experiment 61, in normal animal, forty-eight hours after a dose of 0.66 per kilo, and even more markedly in Experiment 80, forty-eight hours after a dose of 0.25 per kilo, a large quantity of dark-green bile was found).

4. Removal of the spleen alters the character of the subsequent hæmolytic, rendering it slower and more chronic.

As I have shown, there is no more characteristic evidence of a gradual death of the red corpuscles than the presence of large pigment cells within the capillaries of the liver or within the spleen, even as there is no more striking evidence of a more acute hæmolytic involving the liberation of hæmoglobin into the plasma than the presence of pigment within the liver cells. What I find, then, is that after injection of toluylendiamine into spleenless rabbits large pigment cells are to be found in the capillaries of the liver in number and variety such as are never met with in the healthy animal, or ever otherwise found after toluylendiamine poisoning (Experiment 89).

These experiments seem to me to establish two things—first, the importance of the spleen as a seat, if not the chief seat, of active hæmolytic; and secondly, the relative subordinate rôle of the liver in this relation. They show very clearly how little value can, I think, be attached to blood pigment within the liver cells as an evidence that hæmolytic has occurred in that organ; for, as has been seen, it is precisely in this situation that a large excess of pigment is occasionally found as the result of the action of toluylendiamine. How little the liver cells, or even the capillaries of the liver, have had to do with the destruction thus occasioned is now evident, since the removal of the spleen may arrest it altogether.

I conclude then that the pigment found in the liver cells in such cases has been formed from hæmoglobin set free within the spleen. I can see no other way of interpreting these facts. The liver, instead of being the seat of active hæmolytic, has thus merely been concerned in disposing of some of its products, notably of hæmoglobin. I cannot but conclude then that the importance of the liver in hæmolytic—in the actual induction of the destructive changes in the blood—has been much exaggerated. Its rôle still remains sufficiently important, since to it belongs the function of getting rid of the hæmoglobin (and doubtless many other products) thus set free, and of preventing their passage into the general circulation.

(To be concluded.)

## Clinical Lecture

ON

### A CASE OF INTUSSUSCEPTION.

*Delivered at the Middlesex Hospital, July, 1892,*

By J. W. HULKE, F.R.C.S. ENG. &C.,  
SURGEON TO THE HOSPITAL.

GENTLEMEN,—Few cases in surgery are of greater interest than those of “internal obstruction,” under which term we comprehend instances in which the blood-circulation in the piece of bowel implicated is arrested either by some constricting structure, as an adventitious band of inflammatory origin; or by some persistent embryonic structure, as the vitelline duct; or by twisting of the bowel, volvulus; or by the slipping of a piece of bowel through a small adventitious opening in the omentum or mesentery, all of which are strictly instances of “internal strangulation.” We include also those instances in which the circulation is brought to a standstill by intussusception; and we also comprise under it those instances where the lumen of the bowel is lessened, as by the encroachment of a neoplasm seated in its walls; and those where the gut is squeezed by pressure made on its outer surface, as by an advancing tumour originating outside it. Authors whose opinions are justly entitled to respect have objected to this wide use of the term “internal obstruction” as wanting in precision, and as placing together in one category cases of very different etiology. This is true, but in the present imperfect state of our knowledge the employment of the term in such wide sense is warranted by the strong recommendation of practical convenience.

The two questions which instantly present themselves in the bedside study of any case of internal obstruction—two questions a correct appreciation of which should govern the line of treatment to be adopted—are the *nature* of the cause and the *seat* of the obstruction. Students as yet without experience, whose knowledge of internal obstruction is drawn only from text-books in which the symptoms regarded as distinctive of the several forms are laid down with a dogmatic clearness that seems to leave little to be desired, will frequently find themselves in much perplexity at the bedside when in very many instances they find that a certain solution of these two questions is unattainable, and one can only arrive at a probability of greater or less degree—a probability which may amount to a strong presumption, or may be a mere conjecture, and which falls far short of a demonstration, of the nature and seat of the trouble. Instances where these can be certainly known beyond possible error before laparotomy are, I think, not numerous. For an example of such prior certainty I may cite intussusception occurring in the large intestine, where the intussusceptum descends into the rectum within reach of the finger, or even passes the anus and comes into actual view. I mention these doubts not to discourage you, but to incite you to ever closer clinical study. In studying such cases the age of the patient may give a clue, since some forms are more common in later, others in earlier, life. Thus obstruction from malignant disease of the bowel is not often met with until somewhat advanced adult life. Bear in mind, however, that exceptions to this do occur sometimes, of which we saw a striking example a few years since, the patient being a youth of sixteen years, under Mr. Lawson's care. Again, malignant tumours of the bowel are much more common in the large than in the small gut; yet within a few years we have seen instances of these in the ileum and in the duodenum. Again, obstruction due to malignant tumour of the bowel is usually gradual and insidious; yet in the case to which I have just referred the history obtained was that of an acute illness of only a few days' duration. Intussusception is more common in childhood and youth than later, but many cases have been verified in persons of middle and advanced age. In the time at which vomiting begins some have thought to find a hint as to which part of the intestinal canal is involved. Thus early vomiting has been supposed to indicate obstruction situated in the upper part of the canal, and the converse; yet occasionally vomiting has been noticed as one of the first symptoms when the obstruction has been situated at the lower end of the intestinal canal. A

case which I saw in consultation with Mr. Lawson and a medical colleague was a good example of this. The patient, a young woman, had symptoms of acute obstruction of about seven days' duration. Previously in good health, whilst in the act of lifting a heavy weight, she experienced great pain in the lower part of the abdomen. She soon began to vomit, and this was continued, being distressingly urgent at the date of her reception into the hospital. An examination of the rectum revealed its complete blockage, its anterior wall being squeezed back against the sacrum by a large mass external to and in front of the gut; a vaginal examination showed this to occupy Douglas's pouch. Of doughy firmness generally, at one spot this mass was softer, and here fluctuation was thought to be detected. An exploratory puncture proved it to be a suppurating hæmatoma, the contents of which were evacuated by an incision, when all the symptoms of obstruction disappeared and the woman quickly recovered. Pain, when localised and fixed, has been thought to denote with some approach to certainty the situation of the obstruction; but I can recall a case in which the pain was referred to the inguinal region, and the obstruction was found to be in the upper part of the jejunum. The form of internal obstruction to which I particularly ask your attention to-day is intussusception, a typical example of which has very recently been under your observation. The following is a précis of the case, abridged from the dresser's notes.

A plumber, aged seventeen years, was admitted into Foulmer ward on July 17th, 1892, in a state of extreme collapse. The surface of his body was distinctly cold. His eyes and cheeks were sunken. His pulse was rapid, very small and weak. He vomited frequently; the ejecta had a fecal smell and appearance. His abdomen was excessively distended, its parietes tense and hard. The right inguinal region and flank seemed to be rather more resistant than other parts. No stools or flatus had been passed since the beginning of his illness one week previously. The patient's calling—a plumber—had led to his condition being mistaken for lead colic, but at the time he was received into the hospital his symptoms unmistakably pointed to an acute internal obstruction. His excellent health previously and the absence of any history of an antecedent peritonitis discountenanced the idea of constriction of gut by adventitious bands of inflammatory origin; whilst his age and the acuteness of the attack, unfavourable to the supposition of malignant tumour, suggested volvulus or intussusception, the absence of tetanus and of the expulsion of mucus and blood per anum (so often characterising intussusception) appearing to favour the supposition of a volvulus. As laparotomy offered the only chance—though in his desperate condition a very slight one—of saving his life it was proposed, and, as he acquiesced, immediately done. The abdomen was opened by an incision between the umbilicus and pubes, and in the right inguinal region there was quickly found a firm cord-like object of about twice the calibre of a goosequill and about three inches long. This, at first taken to be a band or perhaps a long slender diverticulum or persistent vitelline duct, when traced was proved to be continuous at one end with distended small intestine, and at the other end to be continuous with a considerable intussusceptum, which, together with the sheathing bowel, formed a stout cylindrical mass nearly ten inches in length. The intussusceptum could not be drawn out, but it was in greater part easily extruded by gentle kneading pressure applied to its further end, until a mass about three inches in length only remained. This seemed so tightly engaged that its extrication might involve risk of laceration, it was therefore brought outside the abdomen, and sponges having been carefully packed around it so as to prevent the entrance of fecal matter into the peritoneal sac if the gut should be ruptured, and the fixity of the gut having been ascertained not to be caused by strong agglutination of the opposed peritoneal surfaces, the disengagement of the intussusception was cautiously proceeded with and soon effected. This was, however, not accomplished without the occurrence of three small rents in the peritoneal tunic, which were closed with a fine silk continuous suture. The intussusceptum, after its extrication, assumed a bright, florid-red hue. It was replaced in the abdomen and the incision was closed and dressed in the usual antiseptic manner. Before administering the anæsthetic the stomach was first emptied by the resident medical officer with a syphon of its foul, fecal contents and then flushed out with a watery solution of boracic acid; and a hypodermic injection of ether was given to combat the extreme depression. This depression continued through the night, but towards morning (July 18th) it seemed to be

rather less, and the vomiting also was less. This apparent improvement lasted till midday, when his strength failed and death occurred at 5 P.M., about twenty-four hours after the laparotomy.

At the necropsy made on the following day marks of a widely diffused slight general peritonitis were found, and in the neighbourhood of the lower part of the ileum and cæcum signs of more intense inflammation. The lowest three feet of ileum were intensely congested, their outer surface coated with flakes of coagulated lymph and of a slaty hue. This part of the gut was matted together and between the coils was a little blood clot. At the distance of ten inches from the ileo-cæcal valve was a part of the gut more deeply discoloured, and on separating this a small aperture was found from which fluid feces ran out. As no fecal matters were observed already extravasated it was inferred that this opening was made by the mechanical tearing of the gut at a sloughy spot in its removal. Close to this was a polypus of the size of a damson, attached to the mucosa by a rather wide base. For an extent of six inches below this the inner surface of the gut presented several patches, yellowish, raised and granular in aspect (as of puriform infiltration?), occurring mostly in bands the long axis of which was transverse to the length of the gut. In addition to these were a couple of small superficial sloughy spots. Note, now, two circumstances which make intelligible the occurrence of the intussusception: (1) the presence of a polypus through which a drag would be exerted on the gut by the peristalsis which passes on its contents, and (2) the tetanic contraction of the gut above the polypus which favoured its invagination when pulled on. Without such reduction of size of the entering gut traction on it through the polypus might have been inoperative; and the frequently verified absence of any such assignable mechanical factor as a polypus hints that, given such great inequality of size as that due to spastic contraction of gut, peristalsis of a neighbouring portion may alone suffice to bring about invagination. Note also the florid reddening of the gut when disengaged, so strikingly resembling that occasionally observed in herniotomy when the constriction is removed, and also like that with which you are all familiar—the blushing of the integument on the removal of an Esmarch's elastic bandage from a limb. This it was which gave expectation of restoration of the circulation within the gut, so that it was unhesitatingly replaced within the abdomen. Yet at the necropsy sloughy patches were found in the gut, and had the lad survived a little longer, on the separation of such sloughs, extravasation would hardly have remained absent. His desperately collapsed condition made it urgent to operate rapidly; had sloughs in the gut been present and recognised during the operation, the time required by excision of the irreparably damaged gut and reunion of the ends with suture would not have permitted the adoption of this course, and all we could have done would have been to bring out the ends and secure them in the abdominal wound, thus making an artificial anus, which, had he survived, could have been dealt with later. That which in this case is truly regrettable is that laparotomy was not done earlier. In acute "internal obstructions" the aphorism so pertinent to acutely strangulated (external) herniæ—that delay is a greater danger than is the herniotomy itself—is equally applicable. If recognised in quite an early stage a short time may be spent on inflation, and the measures you will find in medical text-books; but let such time be short, and in the event of minor measures not speedily proving successful, turn promptly to laparotomy with confident expectation of a smaller mortality. Delay and an expectant inaction, leaving such cases to nature, will, it may not be doubted, occasionally terminate in recovery after exfoliation of an intussusceptum and its passage per anum; but bear in mind that such a recovery is not always permanent, and that after an interval the contraction of the cicatrices may lead to renewed obstruction and to death, of which I have known in my own experience more than one example.

Old Burlington-street, W.

**NEW HOME FOR THE DYING AT BRADFORD.**—A committee has been formed for the purpose of opening, in connexion with the Samaritan Home at Bradford, a home where poor women in the last stages of any non-infectious disease will be cared for in their last days, that their passage to the grave may be rendered as peaceful as medical skill and good nursing can make it. Appeals for funds are being made by the committee, it being their intention to open this home, if possible, early in the new year.

## A CASE OF DOUBLE HEMIPLEGIA WITH BULBAR SYMPTOMS.

By J. HUGHLINGS JACKSON, M.D. St. AND,  
F.R.C.P. LOND., LL.D. GLAS., F.R.S.,

PHYSICIAN TO THE LONDON HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE;

AND

JAMES TAYLOR, M.D. EDIN., M.R.C.P. LOND.,  
REGISTRAR AND PATHOLOGIST TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE.

THE patient whose case is here narrated was under the care of Dr. Hughlings Jackson at the National Hospital for the Paralysed and Epileptic, Queen-square. He was first admitted on May 10th, 1889. The following particulars are from the notes of Dr. Risien Russell.

The patient, R. N—, aged fifty-two, suddenly became giddy whilst walking in the street in September 1888. He also lost the use of his left side at this time and had difficulty in talking and in swallowing. His mouth is said to have been drawn to the left. He could not protrude his tongue. The unilateral loss of power gradually passed off, but he has had slowly increasing difficulty in articulating and swallowing. He is said not to have been able to make himself understood at all for four weeks after the attack, and he could swallow only liquids and semi-solids. Food was apt to "go down the wrong way," and on account of this and the "phlegm" which accumulated in his throat he not unfrequently had choking attacks. Five years before he had a similar attack, but then the loss of power was on the right side. He is said to have lost the ability to articulate for a week, and then to have gradually but perfectly recovered this power. There was also improvement in the condition of the paralysed limbs, but slight weakness of the leg remained and this was present when he was admitted in 1889. His wife observed nothing peculiar in his talking, nor had he any difficulty in swallowing before the last attack. She is quite sure that the onset of the first attack, as well as of the second, was sudden. There is nothing of consequence in his family history, but a significant incident in his previous personal history is an attack of gout ten years ago. When admitted he complained of difficulty in swallowing and inability to talk distinctly, and examination revealed the following conditions. As regards the face no notable difference could be detected between the two sides when the eyebrows were raised and in frowning, but in trying to close the eyes firmly the left orbicularis palpebrarum was seen to contract less firmly than the right. In showing the upper teeth the left upper lip was imperfectly raised. The tongue turned to the left on protrusion. There was complete paralysis of the palate, the two sides remaining quite immobile during phonation. Its tactile sensibility was preserved, but its reflex irritability was abolished. There was no paralysis of the vocal cords. These observations on the tongue, palate and vocal cords were confirmed by Dr. Semon. The tongue and muscles of the palate responded actively to faradaic stimulation. The neck movements were well carried out without pain. There was no wasting of any muscles. Movements of the box of the larynx during both respiration and deglutition did not seem to be affected. No wasting or fibrillary twitching was observed in any of the trunk muscles. The arms were fairly well nourished, and so were the small muscles of the hands. There was no fibrillary tremor, and movements were carried out steadily and exactly except that there was slight inaccuracy in touching different parts of the face with the fingers of the left hand when the eyes were closed. The grasps were feeble as tested by the dynamometer—viz., right = 60, left = 50, an ordinary right-handed grasp being about 120 on the same instrument. The triceps and wrist-jerks were well marked and equal on the two sides. There was no local or general wasting of muscles in the legs, and movements were fairly carried out as he lay in bed. No sign of unilateral weakness was evident in his gait, except slight stiffness in the right leg. The plantar reflexes were excessive but equal, both knee-jerks were exaggerated, the right being more active, and slight ankle clonus was obtained on the right side, none on the left. The sphincters of the bladder and rectum were unaffected. Sensibility was quite normal on face, trunk and extremities

As regards special senses, there was no impairment of taste or hearing. He could not smell assafœtida, but he said that his smell had always been defective. His sight with glasses was fairly good. There was marked inequality of pupils, the right being the larger. Both reacted to light and during accommodation. Ocular movements were all carried out well and there was no nystagmus. The following is Mr. Gunn's note on the fundi: "Both optic discs have their edges ill defined, but exhibit no swelling. The veins are considerably congested and the arteries silver-wire like. In the vicinity of the disc in both eyes there are numerous hæmorrhages, chiefly in the nerve fibre layer, but in the right eye there is a guttate one which is probably deeper. There are one or two roundish whitish spots, either due to fatty change in the retina or to old hæmorrhages. Ophthalmoscopic examination points to albuminuric retinitis." There was no aphasia and no impairment of the ability to read and write, but great defect of articulation. He was just able to make himself understood. He could not blow out his cheeks when he attempted to do so, as the air rushed through his nose. He was unable to whistle, although he could formerly. The heart's apex was in the left fifth space in the nipple line. No murmur was heard, but the second sound at the base was accentuated. The arteries were tortuous and the radial could be rolled under the finger. The pulse was of high tension but regular. The chest was barrel-shaped and the costal angle broad. Movements were feeble, but equal on the two sides. Respiration was mainly thoracic as he lay in bed. It was regular. Respirations were twenty-four per minute. Expiration was prolonged, but there were no accompaniments. He complained of difficulty in coughing and of inability to "bring up phlegm." No abnormality was discovered in the liver and spleen. The urine was clear, pale, faintly acid, with a specific gravity of 1010. It contained no sugar, but boiling showed the presence of a copious cloud of albumen. As regards his psychical condition he was very emotional, and laughed and cried easily and without apparent cause, and he could not stop himself from doing so.

The patient's condition remained unchanged during the time he was in hospital, except for some fluctuation in the quantity of albumen present in the urine. He was discharged on September 22nd, 1889, at his own request. On November 20th of the same year he was readmitted, and the following additional particulars of his condition at that time are taken from the notes of Dr. George Wilson, who was clinical clerk of the case. The breathing was husky and the patient complained of his inability "to bring up phlegm." On attempting to cough there was almost no result; inspiration was imperfect and the expulsive part was very feeble and jerky. The voice was rough, husky and nasal. Cotton wool placed in front of the nose was blown whenever he phonated. He could not keep up a prolonged effort of vocalisation. Thus he could not say "Ah" for more than four seconds without taking a breath. The pitch and volume of his voice were greatly impaired. In talking it frequently sank to a whisper and sometimes an attempt at phonation ended simply in a gasp. When he tried to shout as loudly as he could the result was a groan. Articulation was very defective, the defect being intensified, and the difficulty in understanding what was said being increased, by the roughness of the voice and the patient's uncontrollable laughter. He could pronounce very few of the consonants correctly; the sibilants were lost so that he could not hiss. He could not roll an "r." The words he uttered best were "no, no" and "Mama." As to explosive consonants, the following was the condition:—1. Voiceless explosives,—as initials p, t, and k, were preceded by the corresponding nasal. Thus "pea" became "mpea," "tea" became "nten," and if often repeated, "nea;" "kay" became "nkay," and if often repeated apparently "kaying, kaying, kay." If the nostrils were closed he could say "pea" and "tea" correctly, but there remained some difficulty and indistinctness about "kay." As finals, these consonants were frequently correctly articulated. He could pronounce "up," "cat" and "tick" correctly. 2. Voiced explosives. As initials these had the nasals introduced in front of them, "band," "door" and "game" becoming "mband," "ndoor" and "nggame." On repetition "bah" became "ma," "day" became "nday," "gay" became "nggay." If the nostrils were closed "band," "door" and "game" were pronounced correctly. As finals, these were also modified "rub" becoming "rum," "head," "en" and "egg" always "heng." All these peculiarities were intensified when the patient became a little fatigued. There was no aphasia, and ability to read and

write was preserved. The condition as regards swallowing was almost the same as formerly, the act being if anything accomplished with greater ease. In other respects, as regards motor and sensory power, the condition of the kidneys and other organs, little or no difference was to be made out and the patient continued as emotional as before. The vocal cords continued to act well. There was no marked change in the patient's condition during the months which followed, until March 11th. He was able to be up and about all day, at one time laughing almost continuously, at another crying as persistently. On the morning of the 11th March, he suddenly lost consciousness and quickly passed into a condition of coma which ended fatally in a few hours.

The necropsy was made by Dr. Walter S. Colman, who also made the microscopical examinations we shall mention; we are indebted to his notes for the following particulars. On removing the brain a considerable quantity of blood recently effused was found spread out in the subarachnoid space over the pons, medulla and the inferior surface of the cerebellum. This blood came from a rent in the roof of the fourth ventricle. Blood had also escaped from a rent in the corpus callosum. On making horizontal sections at the level of the basal ganglia the lateral ventricles were found distended with blood. The hæmorrhage had apparently had its starting-point in the anterior part of the left lateral ventricle, where it had extensively ploughed up the white matter and the basal ganglia. There was a mass of blood-clot in this region the size of a fist. It had passed into the third ventricle and along the iter, ploughing up the centre of the pons. The finger could be easily passed into the fourth ventricle in this direction. All the vessels at the base were extremely atheromatous. The kidneys were in an advanced stage of granular contraction, and the left ventricle of the heart was hypertrophied. Microscopic examination of the cord and medulla after they had been hardened in Müller's fluid showed extensive degeneration of the pyramidal tracts on both sides from the crura downwards. The degeneration was more extensive on the left side of the cord than on the right, and diminished as the lower levels were reached. The hypoglossal nuclei were normal, the outline of the cells being clear and distinct. The extensive destruction which the fatal hæmorrhage caused rendered the detection of any old lesions in the cerebral hemisphere impossible. From the account of the condition present during the time the patient was under observation, it will be seen that the symptomatology presented a picture resembling that of ordinary progressive bulbar paralysis. Yet the differences, although slight, were sufficient, especially having regard to the history of the case, to enable Dr. Hughlings Jackson to predict a double lesion higher than the bulb. The existence of symptoms usually associated with bulbar disease in cases in which the lesion is a cerebral one has been long recognised. The first record of such a case is by Magnus,<sup>1</sup> and is that of a patient who had paralysis of the facial muscles and of the tongue, with constant dribbling of saliva, and in whom what is called "speech" remained completely in abeyance after a second attack of left hemiplegia. In this case only a single lesion in the right hemisphere was discovered post mortem. There is a very important case recorded by Dr. Barlow.<sup>2</sup> It was that of a boy with aortic disease who had first an attack of right hemiplegia and later one of left hemiplegia. When he came under observation after the second attack his limbs were weak and wasted, but the muscles reacted well to faradism. He was unable to protrude his tongue, but there was no wasting of it, and there was no paralysis of the palate. There was some difficulty in swallowing, but no regurgitation of food. He could not talk, but he understood signs. He was very emotional, and, to quote the report, "he cried like a man with senile softening whenever he was spoken to." At the necropsy there was found to be plugging of both the middle cerebral arteries, and there were areas of softening almost symmetrical at the lower end of the ascending frontal and the hinder end of the middle and inferior frontal convolutions. Similar cases have been recorded by Lepine,<sup>3</sup> by Jolly,<sup>4</sup> by Eisenlohr,<sup>5</sup> by Kirchoff,<sup>6</sup> by Ross,<sup>7</sup> by Miss McNutt,<sup>8</sup> and by Fuller and Browning<sup>9</sup> so that the condition is well recognised.

In the case of R. N.—, recorded in this paper, the important points in regard to diagnosis were the distinct history of two separate attacks of hemiplegia, the absence of the usual wasting of the tongue and of the “squirming” movements which are present in it in bulbar paralysis, and the absence of fibrillary twitching in other parts. On the other hand, the peculiarity of the articulation resembled what occurs in ordinary bulbar paralysis, and the difficulty in swallowing was the same. The emotional condition also was extremely suggestive of the lower lesion. With regard to the condition of the chest movements, it is very difficult to determine how much of the weakness is due to paralysis in a case in which there is emphysema. In this case the chest was emphysematous, and it is on that account probable that a good deal of the chest weakness present was a result of this. This weakness of the chest no doubt accounted for the feebleness of the voice and the difficulty there was in sustaining it, for the vocal cords moved freely and correctly, and what difficulty there was must therefore be ascribed to imperfect bellows action. The difficulty of articulation was of course a different thing, being the result of the paralysed condition of the palate. The conditions which were present in this case find an explanation on Dr. Broadbent's hypothesis,<sup>10</sup> that bilateral movements habitually associated are represented in each half of the cerebrum. This hypothesis has been verified experimentally by Beevor and Horsley,<sup>11</sup> at least as regards certain bilaterally associated movements, such as those of pouting with the lips, mastication, swallowing and adduction of the vocal cords, and further experiment will probably show that it is true of many other movements. In our patient's case, after the first attack of hemiplegia the articulation dependent upon the condition of the palate would be, if at all interfered with, only temporarily so, on account of the preservation of the path on one side. When, however, the second lesion came on the opposite side there was no third path by which impulses could travel to the periphery, and the peripheral mechanism of articulation was consequently rendered inactive, the amount of inactivity being proportioned to the completeness of the interruption. A similar explanation applies to the condition of the chest movements, if the deficiency in those is to be ascribed to anything more than emphysema. It is unfortunate that the fatal hemorrhage was so extensive as to make it impossible to localise the lesions which caused the two attacks of hemiplegia, but that the case was one of double hemiplegia and not of bulbar paralysis is, we think, sufficiently proved by the double descending degeneration visible above the level of the medulla, and by the healthy condition of the cells of the bulbar nuclei. The bearing of the abnormal vascular condition, of the renal disease, and of the state of the fundi is too obvious to need comment.

### THE TREATMENT OF SEVERE CASES OF CLUB-FOOT.

By W. J. WALSHAM, F.R.C.S. ENG.,

ASSISTANT SURGEON AND SURGEON IN CHARGE OF THE ORTHOPÆDIC DEPARTMENT OF ST. BARTHOLOMEW'S HOSPITAL.

At a recent meeting of the Royal Medical and Chirurgical Society Mr. Edmund Owen raised the vexed question of the surgical treatment of severe congenital club-foot and advocated Phelps' open incision as the best method for the cure of the affection. I am entirely in accord with Mr. Owen in thinking there are many cases of club-foot which cannot be effectually dealt with merely by tenotomies and mechanical extension. During my charge of the orthopædic department at St. Bartholomew's Hospital for the last ten years I have met with many such cases; and although I have had them in the

wards for months under my own daily personal supervision I have failed to cure them by these means alone. Some of these cases had been under my own care from the first; but others were relapsed cases that had previously been treated at general and special orthopædic hospitals. I am not convinced, however, that Phelps' open method is the best way of treating these severe cases—indeed, in some of the cases in which I have operated I am sure that without the removal of portions of bone the foot could not have been corrected. For even after, say, the astragalus or a wedge-shaped piece of the tarsus had been excised, although the ligaments and tense structures on the inner side of the foot were freely divided from within the wound, it was not until much more bone had been taken away than I intended when I commenced to operate that the foot could be brought into a fair shape and useful position. In less severe grades than these, when the ligaments and other tense structures on the inner border of the foot and sole have been completely cut through down to the bone, whether by Phelps' open method or by Parker's subcutaneous operation, the foot can be brought into a line with the leg; but it is only at the expense of inserting, as Mr. Owen puts it, a wedge of space between the astragalus and scaphoid on the inner side and a less sized wedge of space between the os calcis and the cuboid on the outer side. Now herein I think lies the weakness both of Phelps' and of Parker's operations. I am not so sure that this wedge of space becomes filled up by granulations, and ultimately by a firm cicatricial pad, as Mr. Owen seems to believe. The condition of the foot after the operation appears to me to be analogous to what occurs after the division of the tendon of the biceps and external lateral ligament for the cure of knock-knee. After these structures have been severed the leg can be brought into a straight line with the thigh, and as long as retentive apparatus is worn the knock-knee appears cured. The down growth of the inner condyle, however—the root of the evil,—has remained untouched, and the rectification is only attained by the insertion, again to use Mr. Owen's words, of a wedge of space between the external condyle of the femur and the corresponding tuberosity of the tibia. This space is not filled up, and when the retaining apparatus is left off—and I am speaking from experience—the knee falls back into the position of genu valgum. I cannot help fearing that the same thing will happen after Phelps' operation, that the new fibrous tissue formed between the divided ligaments and soft parts will draw as it contracts, as all new fibrous tissue will, the deformed and displaced bones back into their faulty position. During the discussion on Mr. Owen's paper Mr. Brodhurst said that the bones were not at fault, and that he had never seen a case in which they were so deformed as to interfere in the slightest degree with the reduction of the deformity. His experience therefore must be contrary to that of most general surgeons. In the museum of St. Bartholomew's Hospital there are now quite a number of deformed astragali removed by my colleague, Mr. Willett, and by myself from severe and intractable cases of club-foot, and illustrations of deformed bones are given in most of the works on Orthopædic Surgery. Indeed, since Mr. Adams drew attention to the condition of the astragalus in his work on Club-foot I was under the impression that it was generally recognised on all hands that in severe cases the deformity and alteration in the articular facets of the astragalus and os calcis were often well marked, and in the case of the former bone sometimes extreme. Seeing therefore that in Phelps' operation the deformity of the bones and the alteration of their articular surfaces are not dealt with, it seems to me that we shall be very liable to have relapses. My own experience of the operation has been insufficient for me to say definitely whether such is or is not the case; and although I have heard from others that relapses after Phelps' method are not uncommon, such cases have not hitherto made their way to the orthopædic department. I admit that the objection I have just raised to Phelps' method may be only theoretical, and time alone can prove the value of the operation.

In some severe cases there is an objection to Phelps' operation which I venture to think is not theoretical. In the class of cases I refer to the equinus position is more marked than the varus, and on attempting to bring the foot up to a right angle after division of the tendo Achillis, and even the posterior ligaments of the ankle-joint, the astragalus is felt to lock against the tibia and fibula. In these cases, as I think I have proved both by dissection and by operations on the foot, the equinus does not depend, as is usually taught, on a mere tilting of the trochlear surface of the astrag-

<sup>10</sup> One of us (J. H. J.) wrote as follows in the *Medical Times and Gazette*, Aug. 16th, 1898: “Moreover, it will be found, I think, that cases of double hemiplegia confirm Broadbent's hypothesis. With regard to this, however, I will content myself by urging those who observe defective bilateral movement with hemiplegia, particularly difficulty in swallowing, to inquire carefully if the patient had not been previously affected on the other side. Again, at a necropsy on a patient known to have been paralysed of but one side, and who had had difficulty in swallowing, we should search both sides of the brain for evidences of disease. For it is a fact that much of the motor tract may be destroyed without the production of hemiplegia, or, at all events, without permanent hemiplegia.”

<sup>11</sup> *Philosophical Transactions*, 1890.

galus out of its socket, but on an abnormal downward as well as inward deflection of the neck. The inward deflection has been long recognised; the downward deflection has not, I think, received the attention it deserves. The reason why the equinus cannot be overcome in these cases after division of the tendo Achillis and the posterior ligaments is that the astragalus is already more or less in normal contact with the tibia and fibula, and further attempts at dorsi-flexion merely wedge the broader anterior surface between the malleoli. To cure the equinus, I hold, either the head and downwardly deflected neck of the astragalus, or in some cases the whole of the astragalus, and often other portions of the bone as well, must be removed. After the excision of the astragalus I have still found that the os calcis or other of the tarsal bones have locked against the external malleolus, and it has not been till parts of these bones have been removed or the external malleolus has been divided and bent backwards that the foot could be placed at a right angle to the leg. When the condition of the astragalus is present it is evident that the mere division of the ligaments and tense structures on the inner side of the foot and even in the sole will be quite futile for correcting the equinus.

In advocating some form of tarsectomy in severe cases I wish it to be understood that no one holds more strongly than myself that these severe cases, like large stones in the bladder, should never be allowed to occur. I have always taught that though I firmly believe these intractable grades of the deformity can only be cured by tarsectomy, at the best it is but a bad job. The foot, after removal of bone, is of course an imperfect member, but at the same time a useful one, and for out-patients to whom the expense of continually wearing apparatus is a great consideration the advantage of being able to dispense with irons is an immense gain. To my mind the moral of the whole question is the importance of undertaking the treatment of club-foot at the very earliest possible period. At birth the bones consist of little more than cartilage, and during the first few months of life can be readily moulded and made to take almost any shape. I have always looked up to Mr. Adams as my teacher in all things orthopædic, and although I differ from him as regards the question of tarsectomy I have hitherto, in the treatment of club-foot in infancy, followed out his method of correcting the varus before attempting to overcome the equinus, and I am bound to say with excellent results. I agree with Mr. Owen that in slight cases the division of the tendo Achillis is often all that is required in the way of operation, but I have certainly found it of benefit to correct by plaster-of-Paris or other mechanical means the varus before doing so.

Weymouth-street, W.

## SIMULTANEOUS DISLOCATION AT THE SUPERIOR AND INFERIOR RADIO-ULNAR ARTICULATIONS.

By T. W. M. LONGMORE, M.R.C.S., L.R.C.P. LOND.

A STEWARD on board a cargo steamer, aged twenty-one, was admitted to the Lady Strangford Hospital, Port Said, under my charge, in June, 1891. He was suffering from the unusual accident of a dislocation of the head of the radius forwards and of the lower end of the ulna backwards. As the causation and symptoms of this uncommon condition were very clear and exact, it seems worth recording. The patient while carrying a dish in his right hand during stormy weather tripped over a ring bolt. He pitched forwards on to the deck, falling upon his right hand, with the injured arm twisted under his body. The radial side of his hand came into contact with the deck, with the wrist bent and the hand pronated; while the weight of his body fell chiefly upon the outer side of the forearm. He felt "something give way," and found he could not flex or extend the elbow-joint, which was fixed in a semi-flexed position. The arm was pulled about by one of the engineers, and afterwards he was able to move the joint more freely. It was then roughly bandaged and put in a sling until he came to the hospital, four days after the injury. On admission, the patient was suffering very little pain or even inconvenience except from inability to use the right arm. The forearm was semi-flexed and the hand

pronated. There were only slight swelling and deformity discernible about the elbow-joint, but when the joints on the two sides were compared a flattening of the outer aspect of the forearm was noticed near the joint, over the position normally occupied by the head of the radius. The bend of the elbow was full, and on palpation a hard swelling was easily felt just to the outer side of the tendon of the biceps, against which it was pressed. On rotation of the radius this swelling was felt to move, and there was absence of movement in the normal position. Crepitus of a creaking character was felt and heard on rotation, but not on simple flexion of the joint or pressure on the radius alone. Passive movement or palpation about the elbow-joint caused very slight pain, but movement of the wrist, especially supination, was painful. The lower end of the ulna was decidedly prominent behind and there was an unusual depression between it and the carpus in front. The end of the bone could be pressed into its normal position with an audible click, but it returned as soon as pressure was taken off. On pronation or supination of the hand the same movement of the end of the ulna took place. When the radius was fixed and the ulna moved forwards and backwards the latter felt perfectly loose and could be separated from the radius and carpus with ease.

After the full administration of chloroform the head of the radius could be felt quite easily resting against the humerus in the bend of the elbow. With skilled assistance attempts were made to reduce the dislocation by fixing the humerus and steadily extending the forearm. At the same time pressure and manipulation over the head of the bone were tried. Then after full extension the forearm was flexed on the arm, at the same moment as downward pressure was made on the head of the radius. Rotatory movements of the radius during both extension and flexion were also tried. Although there was complete relaxation of muscles, yet the position of the head of the bone could be only slightly altered, and at no time did it regain its normal position. There were no signs of fracture or other injury about the elbow-joint, but it did not seem justifiable to make further or more violent efforts at reduction. So the attempt was relinquished and the arm put up in an angular splint midway between pronation and supination. A straight splint was put along the outer side with a pad pressing on the lower end of the ulna, while a similar splint and pad were made to exert pressure on the head of the radius. The splints were kept on for three weeks and were readjusted at the end of each week, when passive movements of the elbow, wrist and finger-joints were made. There was no tendency for the lower end of the ulna to become firmly fixed, so after the splints were removed a bandage and a couple of pads were worn. To restore the muscular power, friction, cold douching and graduated exercise were ordered. As there was no pain all movements were increased and the patient instructed to lift a daily increasing weight from the floor. After five weeks he left the hospital with a very useful arm. Flattening of the outer side of the forearm and fulness of the bend of the elbow were still apparent. Flexion of course was not complete, but he could button his clothes and feed himself. The chief discomfort arose from the condition of the ulna, but when it was properly bandaged inconvenience was only slight.

Cases of these dislocations occurring separately are quoted in "Holmes' System of Surgery," "Spence's Lectures" and the celebrated work on "Dislocations and Fractures" by Sir Astley Cooper. In the last-named work a series of cases of dislocation of the head of the radius forwards are given in detail. In five of these the dislocation was reduced successfully, in six it remained unreduced. In the same work it is said that "luxation of the lower end of the ulna backwards is the result of a sudden and violent pronation." The age of the patient agrees with that given in most of the recorded cases, and the fact of his being a delicate, lightly built lad, with very loose joints, would render dislocation more likely to occur than fracture. The occurrence of the double dislocation was doubtless aided by his right hand being engaged at the moment of his fall, and so, being caught off his guard, he was not quick enough to put it into the usual protective position involuntarily assumed while falling. When it is considered that the annular, the capsular, the oblique and the saciform ligaments connecting the radius and ulna were, in all probability, ruptured, and the two bones only connected by the interosseous ligament, it is wonderful that the result of the accident was not more unsatisfactory.

Woolstone, near Southampton.

## CHRONIC RHEUMATIC ARTHRITIS.

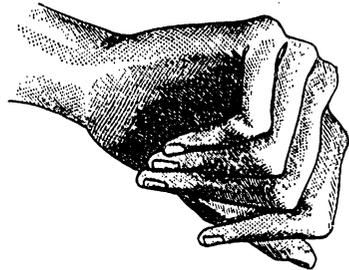

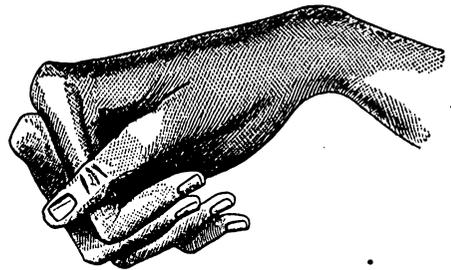

By HUGH LANE, L.R.C.P. EDIN., M.R.C.S.,  
SURGEON TO THE ROYAL MINERAL WATER HOSPITAL, AND HONORARY  
MEDICAL OFFICER TO THE ROYAL UNITED HOSPITAL, BATH.

WITH respect to the subject of rheumatic and rheumatoid arthritis, which I have frequently discussed in the columns of THE LANCET, the following case may prove of interest as exemplifying the distinctions originally drawn by Mr. C. T. Griffiths and myself—viz., that one disease, rheumatic arthritis, is an affection of rheumatic origin, local in character, in which the neural element is absent; and the other, rheumatoid arthritis, is a general disease of debility, having no connexion with rheumatism, in which the neural element plays a conspicuous part, and which occurs in cases with strong hereditary histories of gout and struma or phthisis, and in which the last stage is osteo-arthrititis.

The patient, a female aged forty-three (father living and healthy, aged seventy; mother died of paralysis, aged sixty-four; two brothers and six sisters all living and strong), was healthy and well till nineteen, years of age, when she had subacute rheumatism (attributed to sleeping in a damp bed), which hardly confined her to bed, but she felt pain and stiffness in her knees, shoulders, elbows and thumb-joints. These joints never got better, but remained stiff and painful after the attack, she feeling every change in the weather. This is a strong rheumatic symptom, for in rheumatoid arthritis the weather does not affect the course of the illness to the same extent, and patients will frequently say they feel better in damp or cold weather. She had subsequent subacute attacks in which more joints suffered until every joint got affected, with the exception of the temporo-maxillary articulation, and she ultimately became quite bedridden and has remained so for twenty years. The catamenia came on at fourteen years, and continued regularly. No phthisis or gout in the family history. Every joint is firmly and rigidly ankylosed, not even the slight movement which can nearly always be obtained in the ankylosis occasioned by osteo-arthrititis (the last stage of rheumatoid arthritis), in which case the ankylosis is caused by obstruction to movement by bony outgrowths. The joints are stiffly fixed; no increase in the size of a single joint beyond an apparent enlargement due to wasting of the limbs, which now are so emaciated that they present the appearance of merely skin and bone. The only joint at present in which there is any movement is the jaw, and that is healthy. She some years ago, when not quite so helpless in the spine, used to take care of her sister's child, and alter its position by raising it with her teeth, but now she cannot even turn her head. The joints of the limbs nearly all contracted, elbows at right angles and close to side; knees also bent up, and fingers contracted in palm of hand; skin healthy, colour good; no great anemia; heart fairly normal, but slight mitral bruit; pulse 60 to minute; bowels opened only once a week, and then only with the aid of an enema or aperient; general health good; eats fairly well, and seems cheerful, frequently singing to the children; and, strangely enough, she is plump in the face, the muscles of which do not appear to be wasted; feels well, except in the springtime of the year; urine, sp. gr. 1020; sugar absent; albumen absent; reaction acid; oxalates absent; small quantity of mucus; passes about 300 gr. of urea daily.

The following interesting points show the difference between the two conditions chronic rheumatoid arthritis and chronic rheumatic arthritis:—1. Family history reveals an utter absence of gout and phthisis, which I have always asserted are found in that of rheumatoid arthritis. 2. No nervous symptoms, neuroses, fornication, tingling of limbs, sweating, numbness, pigmentation of skin, and no constitutional symptoms—simply a joint affection; and although every limb is wasted, there is no evidence of general organic progressive disease, as in rheumatoid arthritis, where the muscular atrophy is one of the earlier symptoms, and as a rule precedes the joint affection. 3. Character of joints affected: all firmly ankylosed, with no enlargement, but of course apparently so, owing to the wasting of the surrounding structures; no effusion, and there are absolute flexion and fixation in this case. Flexions of joints in the

vast majority of cases are of rheumatic origin, while in rheumatoid arthritis frequently the fingers are hyperextended, but this is not the rule. The character of the joints affected in rheumatic arthritis contrasts strongly with the condition of the joints in rheumatoid arthritis, where the joints are always swollen, with a sensation under the fingers, as if of fluctuation, the swelling commencing some distance above the joint and terminating some distance below it, and always of a more or less spindle-shape. 4. In this case the temporo-maxillary is the only articulation exempt, oddly enough bringing evidence to prove the correctness of my view, that this joint plays an important part in the differentiation between these diseases,<sup>2</sup> where I pointed out that in rheumatoid arthritis the joints most used are the first to go; and, as everyone must talk and eat, this joint never enjoys a lengthened period of repose, and therefore is frequently the seat of the disease, while in rheumatic arthritis it is rarely affected. 5. Her good spirits; not so in rheumatoid arthritis, when depression is an early and constant feature. 6. The symmetry of the joints affected is another point of distinction but that is not essential in this case, as nearly every joint in the body is affected. 7. No marked anemia, which is so prominent a symptom all through rheumatoid arthritis. 8. Slight mitral bruit, but slow acting heart, soft pulse. In

rheumatoid arthritis the heart's action is rapid, usually over 100, no anæmic bruit is found and there is a hard pulse. 9. Although the illness in this case developed before the usual period, the preponderance of evidence points to this being a case of rheumatic arthritis, as described by Mr. Griffiths and myself.

The importance of this proper differentiation cannot be over-estimated, as upon this treatment entirely hinges—the treatment of rheumatism and rheumatic arthritis by anti-rheumatic medication and non-nitrogenous diet &c.; gout and gouty arthritis by appropriate medicinal treatment, depletion, diet &c.; and, finally, that of rheumatoid arthritis, in which case the strumous element so much predominates<sup>3</sup> that it has now caused quite a revolution in the treatment, approximating it to that of struma or phthisis, by cod-liver oil, tonics, stimulation and building up. It must be clearly and distinctly regarded, not as a result of rheumatism or as a hybrid condition, the diagnosis and nomenclature of which were scamped under the absurd appellation of rheumatic gout, but as a distinct disease possessing strong and peculiar features of its own, an offspring of the hereditary tendencies of gout and scrofula. Of course, from the facts of a single case like this it is impossible to deduce any absolute principles, but I hope it will be a link, though a single link, in the chain of evidence which I have previously brought forward in a large number of cases.

THE AXIS-TRACTION FORCEPS.<sup>1</sup>

BY CHAS. J. CULLINGWORTH, M.D. DUR. &c.,  
OBSTETRIC PHYSICIAN TO ST. THOMAS'S HOSPITAL ETC.

EVERY teacher of midwifery has to make up his mind what kind of forceps to recommend to his pupils when they commence practice. It is all very well for obstetric experts to possess a variety of instruments, and to say that, under such and such circumstances, *this* is the proper instrument to use, and, under other circumstances, *that*. The ordinary practitioner cannot be expected habitually to carry about with him more than one pair of forceps, and that pair obviously should be capable of being used in any case in which delivery by the forceps may be called for. There are of course other conditions besides this of universal applicability that are essential in a good pair of forceps. For example, it should be an instrument easily kept clean and aseptic, and, furthermore, it should in its construction be up to date—that is, it should represent all the more recent improvements, provided they have stood the test of experience and have proved to be real and are not the mere modifications of a faddist. The history of the midwifery forceps is full of interest from the first chapter to the last. The gradual evolution of the instrument from its original crude form to the shape in which it is now familiar to us is a history that always fascinates the student and at the same time teaches him the uses of the various parts of the instrument in a way that nothing else can. In the earlier part of my career as a teacher it

was held and taught that in the long forceps with the double curve we had arrived at something very near perfection. That instrument was in use throughout Great Britain. It was generally known in Scotland under the name of Sir James Simpson's forceps, and in the north of England under that of Robertson's; whilst in London and the south it usually bore the name of Robert Barnes. Each of these names indicated slight differences in construction, but in all their main features the three instruments were the same, their geographical distribution being more a question of local patriotism or of loyalty to an individual teacher than of any marked superiority in the particular instrument. For many years, however, there had been a steadily growing conviction in the minds of many obstetricians that the long double-curved forceps was not an altogether satisfactory instrument. The addition of the pelvic curve had ensured the more equable distribution of the grasp of the blades over the fetal head, and so had removed one of the great objections to the straight forceps, but it had not altered the direction of the tractile force. If the handles of the instrument be carried as far back as the perineum can be stretched, the direction of the traction can never correspond with the axis of the pelvic inlet. This axis, along which the mass of the fetal head must enter the brim, is coincident with a line drawn between the umbilicus and the coccyx. If traction could be made in this line there would be no misdirection of the force—it would all be available for the purpose aimed at; but exactly in proportion as the line of traction diverges from the axis of the genital canal so some of the force is expended in

driving the head of the child against the anterior wall of that canal, and is therefore not simply wasted, but acts to the detriment of the maternal tissues. With the ordinary forceps it is anatomically impossible for traction to be made directly in the pelvic axis, so that a certain amount of the force expended is ineffective. From the year 1860 forwards several attempts were made to remedy this defect by giving a backward or perineal curve to the handles. The most effective device for the purpose, however, was that which we owe to M. Tarnier, of the Paris Maternité, and which he described in the year 1877 under the term of "axis-traction forceps." The essential features of this instrument are the metallic traction rods. These rods, at their upper end, are attached by a hinge-joint to the posterior edges of the blades, and fit, by their lower extremities, into a single curved stem, at the other end of which is a transverse bar, movable in all directions, called the traction handle. When the instrument is in use, the rods lie closely applied against the shanks, while the curve of the stem connecting the rods with the handle carries the handle just sufficiently far backwards to ensure that the direction of the tractile force shall corre-

spond with that of the axis of the pelvic canal.<sup>2</sup> Immediately below the lock and in front of the handles is a fixation screw, by means of which the handles are kept in contact and the amount of compression exercised by the instrument carefully regulated. In using the ordinary double-curved forceps, the operator keeps the handles in apposition by his own grasp, but inasmuch as in all axis-traction forceps traction is exercised solely by means of the traction handle, it is unnecessary, and indeed undesirable, to maintain any hold upon the ordinary handles when once the instrument has been properly introduced and locked. Hence

<sup>2</sup> Dr. Milne Murray (Edinburgh Medical Journal, Sept. 1891) has given the following method for testing the accuracy of any given instrument in regard to this curve (see Fig. 2):—"A piece of paper about eighteen inches square should be firmly stretched on a drawing-board or other smooth surface. A pencil line should be drawn down the centre of the paper. Place the left blade of the forceps on the middle of the paper so that the shank coincides with the line already drawn, the hollow side of the blade being upwards. Trace an outline of the blade on the paper, holding the pencil perfectly vertical in doing so. Mark the point at which the shank joins the curve of the blade; call this point Y. Mark the centre of the tip of the blade; call this point X. Join X Y by a straight line. This will form the chord of the arc which forms the middle of the curve of the blade. Bisect X Y by a line at right angles to it, E F. Describe a circle, G X V H, whose centre lies on E F, and whose circumference touches X and Y. The arc X V Y lies in the middle of the blade. Now draw a tangent, A B, to the circle X V Y, at the point V. This will be parallel to the chord X Y. Now lay the blade on the paper in its original position, taking care that the points X and Y correspond precisely with their position on the forceps. If the traction rods Z T are properly constructed, the stud T will lie on the line A B, when the rod lies close to the shank."

<sup>1</sup> An address read before the Metropolitan Counties Branch (East London and South Essex District) of the British Medical Association, Nov. 17th, 1892.

arises the necessity for the fixation screw just described. Without some such contrivance the handles would fall asunder and the instrument become completely disarranged. The advantages claimed for this instrument are as follows:—

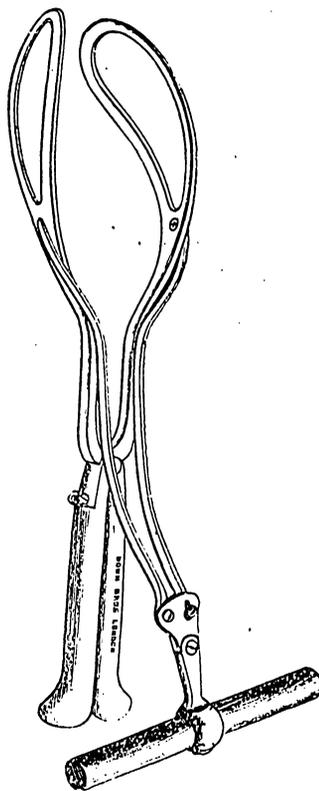

1. The traction rods, permitting traction to be made in the axis of the inlet, ensure that all the force expended by the operator is exerted usefully, and that the maternal tissues are exposed to no unnecessary pressure. 2. The application handles move forwards as the head descends in such a way as to furnish a constant guide to the direction in which traction should be made in order that it may be exercised with most effect—i.e., the direction proper to the plane of the pelvis through which the head is passing. 3. The transverse handle enables the operator to keep up a steady and continuous pull with a minimum of muscular fatigue, and therefore with the power of estimating with some approach to accuracy the amount of force he is expending. The first of these advantages Tarnier's instrument shares with Hubert's, Aveling's and some others of its predecessors. The second and third it does not; they are peculiar to itself. The objections which have been raised against Tarnier's forceps are that it is costly, unwieldy and complicated. These objections are no doubt well founded, but they are not altogether insuperable. The design of the instrument did not issue from the brain of its originator in a state of irreproachable perfection. Its details, as must always be expected in the earlier attempts to carry out a new idea, were open to criticism and capable of improvement. But its principle has stood its ground in spite of all the criticism that it has encountered; and that, after all, is the main fact that concerns us. The advantages are unmistakable and permanent; the disadvantages are for the most part accidental and removable.

As early as 1880 Professor Alexander Simpson of Edinburgh introduced a series of valuable modifications which had the effect of removing many of the objections urged against the instrument. These modifications are mainly as follows: 1. The instrument is an adaptation of the principle of Tarnier's forceps to the ordinary forceps in use in this country, and hence is much less bulky and complicated than Tarnier's. 2. The traction apparatus, including the handle and locking plate, which in the French model is detached from the rest of the instrument, is permanently attached to the blades; no part of it therefore can be mislaid or forgotten. 3. The fixation screw is greatly reduced in size, in order to emphasise the fact that the screw is not to be used for purposes of compression, but of adjustment. The instrument as thus modified has become widely popular in Scotland and amongst those English practitioners who received their professional training in Edinburgh. In the south the principle of axis traction has never been so heartily accepted or so generally taught as it has been in the north, and the great majority of English practitioners are still practically unacquainted with it. Even those who were present when Tarnier's instrument was first exhibited in this country, and to whom it therefore cannot be said to be entirely unknown, were for the most part so repelled by its bulk and complexity that they took no further interest in it. The merit of Professor Simpson's modification was that without sacrificing any important principle in its construction it in great measure got rid of those features. Other modifications have been proposed in abundance. A large number of them consist of loose traction rods, more or less resembling boot-hooks, which are to be hooked into the lower angle of the fenestræ or other convenient place, and traction made backwards. It need scarcely be said that such an arrangement, whether in itself advantageous or not, is not axis traction. It may be possible by its means to make traction in the axis of the inlet, but the guidance afforded by the application handles in Tarnier's instrument is forfeited, and no guarantee is provided that the direction of the tractile force shall alter as labour advances, and shall be at all times suitable to the part of the pelvis through which the head is passing.

It will have been inferred from what I have already said that I believe the axis-traction forceps to constitute the most important improvement that has been made in the construction of the instrument since the introduction of the pelvic curve. No one who has used it sufficiently often to overcome the slight difficulty at first experienced in its manipulation will ever willingly return to the older form. It can not only accomplish all that the older instrument can accomplish, and do it more easily, but it can accomplish more—for it will not infrequently succeed where the latter has failed. I am myself firmly convinced that the general adoption of the principle,

at least, of axis traction, the truth of which is capable of mathematical proof, is merely a question of time. It was in the form of Professor Simpson's modification of Tarnier's forceps that I first became practically acquainted with the instrument. It will therefore be readily understood that, as a mere matter of sentiment, I have been loth to suggest any alteration in the Edinburgh model. When, however, in the year 1889 Messrs. Down Brothers informed me that they were about to make some axis-traction forceps in order to meet the demand consequent upon my recommendation of them, and asked me which pattern I should recommend them to adopt, it seemed a suitable opportunity for proposing some slight modifications in Professor Simpson's instrument that experience had convinced me would still further increase its value. These proposals they at once proceeded to carry into effect, the result being the instrument shown in Fig. 3. It differs from Professor Simpson's chiefly in being generally firmer and more unyielding, in being furnished with stronger screws and a stronger stud on the traction plate, and in its being made entirely of metal. The object of these alterations is to provide

FIG. 3.

Modified axis-traction forceps.

an instrument that will not bend; that, being made specially strong in its weakest parts, will not be likely to fail at the supreme moment by the giving way of those parts; and that, by having no woodwork about it, can be rendered thoroughly aseptic by boiling. The total length of the instrument is 14½ in. The handles are 5½ in. long, the shanks 2½ in., and the blades, measured along the chord of the arc, 6½ in. The shanks are very strong and are ¾ in. apart. The greatest width between the blades is from 3 in. to 3½ in., and the distance between their extremities (when the instrument is locked and the application handles in contact) is ¾ in. Each blade has a maximum breadth of 2¼ in., and a fenestra 4¼ in. long by 1½ in. wide. The traction rods are screwed on to the solid part of the blade, immediately below the fenestræ, so as to allow of antero-posterior movement only. A key is sent with each instrument for unfastening these screws for cleaning purposes. The fixation screw is the same as in Professor Simpson's instrument, but is somewhat stronger. The design of the locking plate and the traction handle is also the same, but again the screws and knobs are of stronger construction.

I have purposely delayed publishing any description of it until its practical value has been repeatedly tested. It has now been used a good many times both at the General Lying-in Hospital and in the maternity department at St. Thomas's Hospital, and has been found to be a highly efficient instrument. The delay has enabled me to suggest an important alteration of the original model. The blades were unnecessarily wide apart between the fenestræ and the shanks, causing premature distension of the perineum as the head descended. That defect has been removed. The instrument is, I am aware, heavier than is desirable, but this fault appears to me to be more than counterbalanced by the ease with which, being constructed entirely of metal, it can be efficiently disinfected. It has been a matter of considerable interest and gratification to me to observe that Dr. Milne Murray of Edinburgh, approaching the subject from a more theoretical standpoint, has quite independently suggested a modification of Professor Simpson's instrument that in many respects resembles the one here described. I am sure Dr. Murray will believe me when I say that I had not seen his paper at the time my own suggestions were being worked out.

It may be useful, in conclusion, to give a few plain directions for applying the axis traction forceps. 1. Introduce first the left blade, to which the traction bar is attached. 2. Before introducing the right blade see that its traction rod is swung forwards, otherwise there will be difficulty in locking the instrument. 3. When the blades have been locked, swing back the traction rod of the right blade and hook it on to the traction plate. 4. Holding the instrument by the application handles, estimate the degree of compression that is desirable and tighten the fixation screw so as to keep up the compression at that point. 5. After this has been done leave the application handle untouched. 6. Make traction with the traction handle, keeping the traction rods parallel with the shanks. 7. Complete the delivery of the head before removing the forceps. This gives the operator greater command over the head, enabling him to prevent its too rapid expulsion and to make traction when there is least strain. 8. As soon as the head is born, loosen the screw, set free the right traction rod and remove the blades, first the right and then the left.

I have to acknowledge the great help I have derived in the preparation of this short address from the admirable monographs on the subject contributed to the *Edinburgh Medical and Surgical Journal* by Professor A. R. Simpson<sup>3</sup> and by Dr. Milne Murray,<sup>4</sup> to which, as well as to Tarnier's original account of his instrument, I must refer those who may desire fuller information as to its theory and scope. Dr. Murray's masterly exposition of the mechanical principles involved in the construction of the axis traction forceps gives to his paper a special and altogether unique value.

## TWO CASES OF NON-SUPPURATIVE TRAUMATIC PERITONITIS IN CHILDREN.

BY G. A. SUTHERLAND, M.B. EDIN., M.R.C.P. LOND.,  
PHYSICIAN TO THE NORTH LONDON CONSUMPTION HOSPITAL;  
REGISTRAR TO THE PADDINGTON-GREEN  
CHILDREN'S HOSPITAL.

IN a recent number of THE LANCET<sup>1</sup> Mr. Edmund Owen has recorded a case of traumatic peritonitis for which he performed laparotomy, with almost immediate cessation of the acute symptoms and complete recovery in a few weeks. From the nature of the original injury and the subsequent symptoms Mr. Owen expected to find pus and some visceral lesion in the abdominal cavity, but instead he only discovered a large accumulation of blood-stained serum and clots, with signs of peritonitis. Such cases are but rarely met with, and the following notes may be of interest as the results of treatment confirm the opinion expressed by Mr. Owen. The patients were in the Paddington Green Children's Hospital under the care of Mr. Watson Cheyne, to whom I am indebted for permission to record the cases.

CASE 1.—A child twelve months old was admitted to hospital on Nov. 19th, 1889. Four weeks previously Mr. Cheyne

had tapped a congenital hydrocele of the right side. The mother had not noticed anything wrong with the child, apart from the reappearance of the hydrocele, until four days before admission, when she discovered that the abdomen was swollen. During the last few days there had been occasional sickness. The patient was a well-nourished infant, but distinctly anæmic. On admission the temperature was 101° and the pulse 146. There was no sickness and no evidence of pain. A large hydrocele was present on the right side, the contents of which could be easily returned to the abdominal cavity. The abdomen was very distended, tense and tender to the touch; on the right side there was absolute dullness extending from the spine posteriorly to within a finger's breadth of the middle line anteriorly, and from the ribs above to within a short distance of the pubes, and fluctuation was distinct over this area. The left side of the abdomen appeared to be normal, and the liver and spleen were not enlarged. On the sixth day after admission the temperature had risen to 103°, while the child was more anæmic and seemed in great pain, moaning incessantly. Mr. Watson Cheyne tapped the hydrocele with a trocar and cannula and drew off four ounces of blood-stained serum, and as this did not reduce the swelling higher up, he proceeded to tap the abdomen in the middle of the dull area and drew off six ounces and a half of a similar fluid. No improvement followed. The abdominal swelling was not removed, the hydrocele quickly refilled, the anæmia increased, and the temperature rose to 104°. Accordingly two days later Mr. Watson Cheyne opened the abdomen in the middle of the right linea semilunaris and evacuated a large quantity of blood-stained fluid. On introducing his finger he felt a soft fluctuating mass in the right iliac fossa, the wall of which gave way, and another rush of similar fluid took place, accompanied by the disappearance of the scrotal swelling. The septum thus ruptured was extremely thin, and seemed to be of fibrinous structure. The finger passed easily from the peritoneal cavity into the right tunica vaginalis. The fluid removed contained no clots, but coagulation took place to some extent in a specimen put aside. The small intestine presented at the abdominal wound, and, with the exception of slight congestion, seemed healthy. The wound was then closed, a small drainage-tube being left at the upper end. Next day the temperature was normal and the patient was free from pain. There was very little discharge from the wound, and the tube was removed on the third day. The child made a good recovery and was discharged cured at the beginning of January, there being still a certain amount of resistance to be felt on palpation over the right side of the abdomen. This was probably due to thickened peritoneum and had entirely disappeared when the child was seen a year later. There had been no return of abdominal trouble and the child was in good health.

CASE 2.—A girl aged eight years was admitted to hospital on Aug. 8th, 1888, having been knocked down and run over by a cab. The wheel was said to have passed over the abdomen. The patient was suffering from shock, being quite blanched and almost pulseless. There was considerable bruising about the face, but no fracture anywhere. She complained of great pain in the back and in the epigastrium, and lay in bed with her thighs flexed on the abdomen. On the following day the abdomen was distended and tender in the epigastric region. She suffered greatly from thirst, and was sick after taking food. The breathing was entirely thoracic, the muscles of the abdomen being kept rigid. Three weeks later the pain and sickness had ceased, but the temperature at night ranged between 100° and 101°. In the epigastric region a distinct swelling could be seen and felt, extending downwards from the ensiform cartilage to within an inch of the umbilicus and passing beyond the edge of the rectus muscle on each side. As counter-irritation had no effect on this swelling, which increased in size, and fluctuation could be made out, it was aspirated a fortnight later, and ten ounces of dark-green fluid were removed. The fluid contained a large amount of albumen and red blood corpuscles. The temperature the same evening was lower than it had been for some nights, and became normal two days later. She was discharged well in three weeks, but there still remained some thickening in the epigastric region.

The course of these cases was clearly distinct from that seen in peritonitis, due to the rupture of some abdominal viscus. In the latter suppuration is soon present, and the whole course of the illness, which usually terminates fatally in a few days, is acute. In the former, and also in Mr. Owen's case, the course was more chronic, the symptoms were those of progressive disease, and suppuration was not present. The

<sup>1</sup> Sept. and Oct. 1890, and Oct. 1893. <sup>4</sup> Aug. and Sept. 1891.  
<sup>2</sup> Oct. 22nd, 1892, p. 936.

rapid improvement noted in all cases after evacuation of the blood and serum supports Mr. Owen's view that this is due to the relief of tension; but, on the other hand, much greater tension is often present in the abdominal cavity without causing any discomfort. The employment of a trocar and cannula, or, better still, of an aspirator, may sometimes be sufficient, as in Case 2; but in Mr. Owen's case the presence of blood-clot and in Case 1 the presence of a septum rendered laparotomy necessary for complete success. In the above cases the progressive anæmia was a marked symptom, and suggested that the effusion of blood continued for some time after the original injury. In Case 1—which presumably in the absence of any history of other lesion was due to the tapping of the hydrocele—the amount of blood found seemed out of all proportion to the extent of the injury.

### HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

#### ST. THOMAS'S HOSPITAL.

INGUINAL ANEURYSM TREATED BY LIGATURE OF THE EXTERNAL ILIAC ARTERY BY THE INTRA-PERITONEAL METHOD.

(Under the care of Mr. MAKINS.)

CASES in which it is necessary to ligature one of the iliac arteries for aneurysm are very rarely met with in surgical practice, and the fact that the ligature was applied in this instance through the peritoneum makes this account of especial interest. There are few instances on record where a ligature has been applied to the external iliac by the method described below, and it is worthy of remark that on the same day that Mr. Makins performed his operation Mr. Mitchell Banks operated on a similar case at the Liverpool Royal Infirmary, also with success. His patient, aged sixty-three, was of spare frame; the aneurysm was situated on the right side, was as large as a fist and of some weeks' duration. Catgut was used to ligature the vessel, and the coats were not divided. The patient left the hospital on the forty-first day after the operation. Mr. Makins draws attention in his remarks to the anatomical difficulties which may be met with, and also directs attention to the possibility of greater risk of hernia after this method. Mr. W. H. Brown, who appears to have also performed the ligation of this vessel through the peritoneum, found it very difficult to reach; but details of the case are wanting. We hope that the publication of this case will lead to the record of others, for the intra-peritoneal method (or, as we prefer to call it, the "transperitoneal") will doubtless be favoured by operators in the future. The records of ligation of the common iliac artery are more numerous than those of the artery which we are considering; but we only wish to direct attention to the latter, though it is quite possible that the operations on the common iliac of Dennis in America and of Rivington and Lucas in this country have led to the fuller consideration of this subject.

The patient was a carpenter aged thirty. Family history good; father, three brothers and two sisters alive and in good health. Mother died at fifty-four; cause of death unknown. He has, on the whole, enjoyed good health, except an uncomplicated attack of acute rheumatism three years and a half ago, gonorrhœa in youth and four years ago he acquired syphilis, which does not seem to have been thoroughly treated. At present there are no evidences of tertiary syphilis beyond the presence of the aneurysm. His occupation at times gives him heavy work and exposes him to the liability of strain.

Sept. 16th, 1892.—For the past twelve months he has noticed that when he slept on his left side he awoke in a cold perspiration and experienced considerable pain in the left groin and neighbourhood. Four months ago he thinks he

strained himself lifting a heavy wardrobe. Three months ago he noted pain and pulsation in the groin, and during the past six weeks swelling and pain down the front of the thigh to the knee. No pain referred to the testicle. These symptoms have been gradually becoming more severe, and on Sept. 15th he was sent to the hospital by Mr. Winterburn.

On admission the patient was a stoutish man of ruddy complexion, due to dilated capillaries and considerable development of subcutaneous fat. The limb was much swollen and œdematous. In the left groin there was a large oval pulsating tumour in the course of the external iliac and common femoral arteries. It extended upwards about two-fifths of the distance between the middle of Poupart's ligament and the umbilicus and for about two inches below the ligament; it was about two inches in breadth. The tumour was hard, the pulsation expansile and synchronous with the heart beat; there was a rough double bruit. Pulsation in the posterior tibial artery was weaker than on the sound side. The area of cardiac dulness was not increased, the first sound was somewhat indistinct at the apex, and the second sound accentuated over the aortic area, but there was no distinct murmur. Pulse 70-80, rather irritable; there was no marked evidence of general arterial disease; no evidence of any other visceral disease; urine, sp. gr. 1018, clear, no albumen, deposit of phosphates; bowels regular; temperature 98.8°. He remained quiet in bed during the next four days, during which time the pulse subsided and the heart's sounds and action became normal.

On Sept. 20th, the patient being under the influence of an anæsthetic of mixed chloroform and ether, an incision four inches in length, commencing one inch below the level of the umbilicus, was made in the left linea semilunaris. The incision was carried through the abdominal wall into the peritoneal cavity and was slightly enlarged downwards, and the deep epigastric artery, which originated in the tumour, doubly ligatured and divided. The small intestines were held over to the right with Messrs. Ballance and Edmunds' broad abdominal retractor, the sigmoid flexure was pushed upwards and an incision was made through the lower part of its mesentery and the peritoneum at the margin of the pelvis in the course of the artery. The wound was deep, there being about an inch and a half of subcutaneous fat and abundance of fat in the subperitoneal tissue both beneath the anterior abdominal wall and around the vessels. This, together with some retching on the part of the patient, rendered the freeing of the artery and the passage of the ligature a process of some difficulty. The spermatic vessels also were exposed and swelled up considerably in the wound. The artery was secured about three-quarters of an inch below the bifurcation of the common iliac and an inch and a half above the aneurysmal sac, and lay somewhat deeply at the inner margin of the psoas muscle; two threads of stout flossy sterilised silk were tied separately, but in close apposition, with sufficient firmness to rupture the internal and middle coats. The posterior peritoneum was sutured over the artery, and the abdominal wound closed with silk-worm gut sutures. Bicyanide dressings were then applied and a flannel roller. Pulsation in the aneurysm ceased entirely with the application of the ligatures.

The after progress of the case was in all respects satisfactory; the patient complained of some pain in the limb for the first few days, and the front of the thigh was markedly cold in contrast with the buttock. The circulation in the foot was throughout satisfactory, quick return of blood being noted after pressure upon the toe-nail on the second day. The general bodily temperature rose to 99.4° on the first two evenings, and afterwards remained uninterruptedly normal. There was never any abdominal pain, tenderness or distension.

On the seventh day pulsation was palpable in the anterior tibial artery. The bowels were opened by an enema, the wound was dressed for the first time, and the stitches removed, as it was found completely united. A week later the patient complained of some discomfort, and on examination it was found that the subcutaneous section of the wound had gaped in its central part, windowed strapping was applied, and in ten days complete union again took place. On the twenty-fourth day an abdominal belt was fitted to support the cicatrix, and on the thirtieth day he was allowed to sit up in a wheel chair. The aneurysm remained hard and firm, with no trace of pulsation throughout, and gradually diminished in size. On the forty-fourth day he was allowed to walk, and on the forty-seventh he left the hospital. The aneurysm now occupied about two-thirds the area it did before

treatment; it was hard and painless. The limb was warm, the tibial arteries both palpably pulsating, and except for slight numbness in the foot he felt well. Three weeks later he was still improving.

*Remarks by Mr. MAKINS.*—The reason for selection of the intra-peritoneal method in this case was the high position of the aneurysm. Before operation the pulsation in the iliac fossa was so forcible and extensive that it seemed probable that it might prove necessary to ligature the common iliac, and it was thought that this would be more readily performed by the intra-peritoneal method. Beyond this the intra-peritoneal method seemed to offer the great advantage of not in the least interfering with the coverings of the sac, which by the ordinary method might have been disturbed by the stripping of the peritoneum. The experience gained by the operation showed that the usual method might have been safely adopted, but this could not be definitely determined beforehand. An advantage was gained in ready access to the deep epigastric artery, which, as directly feeding the sac itself, needed ligature, but of course might readily have been secured by an extension of the ordinary wound. As to the comparative difficulty of the two operations, I think there is little to choose, and on the whole the incision for the extra-peritoneal method is perhaps to be preferred in the matter of cicatrix; in the vertical incision the advantage of suturing the fibrous structures in the linea semilunaris is gained; but, on the other hand, the resulting cicatrix passes directly through from skin to peritoneum. In the oblique incision the decussation of the various muscular layers leads to a certain intricacy and irregularity in the line of the cicatrix which may render it the stronger, since pressure is less readily brought to bear directly upon it. The choice of the iliac vessels obtained is, I think, a real advantage, since the incision needs neither extension nor modification; but in saying this it should be pointed out that this is a much stronger argument on the right than on the left side of the body. Ligature of the right common iliac artery by the intra-peritoneal method is probably the easiest of all the operations on the great arteries, since the vessel lies directly beneath the peritoneum of the posterior abdominal wall uncovered by any structures of importance. On the left side, on the other hand, the inferior mesenteric vessels as they enter the sigmoid mesocolon and pass down to the mesorectum cover practically the whole of the artery, and to reach the common iliac comfortably and safely the peritoneum would need to be divided close to the left of the median line of the sacrum and then displaced outwards. This manoeuvre has the disadvantage of exposing the vein freely, but this would probably give far less trouble than the numerous mesenteric vessels would when swollen by reason of the loss of their peritoneal support. In the case recorded above the distension of the spermatic vessels when set free by the division of the peritoneum was much greater than would have been expected.

### ANCOATS HOSPITAL, MANCHESTER.

THREE CASES OF COMPOUND DEPRESSIONED FRACTURE OF THE SKULL TREATED BY ELEVATION AND REIMPLANTATION OF FRAGMENTS, AND WITHOUT THE USE OF THE DRAINAGE-TUBE.<sup>1</sup>

(Under the care of Dr. P. TYTLER.)

THE treatment of compound depressed fractures of the skull has of late received considerable attention in our columns,<sup>2</sup> and we would only direct our readers to some of the more important points which bear out our former statements with regard to such cases. These are the reimplantation of bone, whether removed with the trephine or broken by the violence of the injury, and the closure of the wound without drainage. In these three cases the treatment was similar, the wounds were made thoroughly aseptic, perchloride of mercury was the antiseptic used, and fragments were replaced. Under these circumstances it is interesting to note that the only patient who had any necrosis of replaced fragments was the one aged thirty-eight, in whom the bone was hardest and least vascular. The youth of the patients and the healthy state of the bone have been the conditions most evident in the cases where full success has been attained, like Cases 1 and 3.

**CASE 1.**—A boy aged six years was on May 5th, 1892, admitted with a compound depressed fracture on the right side of the skull, immediately above the ear, caused by a blow from a swing-boat. The patient had suffered from symptoms of shock when first admitted, but these had disappeared when Dr. Tytler saw him about three hours after the accident. The wound was washed with antiseptic lotion and the scalp was shaved for three inches round, and then thoroughly cleansed. After the patient was under chloroform the wound in the scalp was found to be at the posterior end of a marked depression of bone. The wound was enlarged upwards by a vertical incision for about an inch; this incision was then extended forwards and downwards in a semilunar form to half an inch below the level of the fracture, passing in front of its anterior end. The flap thus outlined was reflected, displaying a gutter-like depression about an inch and a half long, formed by two long narrow fragments of bone bent in towards each other, gradually sloping and deepening towards the posterior end, where the groove was abruptly terminated by one large and several minute pieces turned nearly vertically inwards. The depression would be about three-quarters of an inch deep at its posterior end, and rose gradually to the surface at its anterior extremity. The pieces of bone were firmly wedged together, and left no opening for the elevator or sequestrum forceps. By means of a sharp chisel a notch was gently made in the sound bone at the upper aspect, so as to allow force to be brought against the upper fragment. On introducing the elevator it was easily dislodged, and the other pieces were then carefully removed without much difficulty. (All the fragments were on removal immersed in warm perchloride lotion.) After removing the end-pieces a small hole was found in the dura mater at the posterior end of the opening, where the end-pieces had been turned in vertically. There was a flow of blood and cerebro-spinal fluid from the opening. (Mr. Williamson, the house surgeon, had reported the discharge of cerebral fluid from the wound on the patient's admission.) After some small blood-clots were removed cerebral pulsation appeared. The whole field of operation was then deluged with warm perchloride lotion and cleared of all clots and debris, after which there was no bleeding which required attention. The largest fragment of bone was then placed on the dura mater and two or three small chips to fill up the vacant corners. As much periosteum was spread over the pieces as could be got. After removing the artery forceps, no vessel requiring ligature, the scalp was replaced and secured with silver sutures, applied chiefly at the points where the artery forceps had been. No drainage-tube was employed, but the wound opposite the fracture was left unsutured for an inch, so that any effusion could easily make its way out. Iodoform was then sprinkled thickly over the external wound, after that iodoform gauze and then a wood wool pad. These were secured by a gauze bandage and several long strips of strongly adhesive plaster applied as a bandage over all. The patient was then put to bed and kept on low diet for a fortnight. Happily for the patient the wound has no further history except the removal of the dressing four weeks later, when sound healing was found all round; the sutures were *in situ*, as harmless as earrings, without a trace of inflammation or ulceration. The patient was discharged well on June 6th.

**CASE 2.**—A woman aged thirty-eight was admitted on May 6th, 1892. She had sixteen wounds on the head, inflicted with an axe, varying in severity from superficial abrasions to gashes several inches long reaching down to the dura mater. The patient having rallied from the shock and hæmorrhage, the scalp was shaved and washed with 1 in 40 carbolic lotion. Under chloroform the following compound fractures were made out: (1) the front portion of the right parietal bone had been cut through with the axe down to the dura mater; (2) another fracture of the same kind was found in the posterior portion of the parietal; (3) another of the same kind, but not quite through the bone, appeared in the upper part of the occipital bone; (4) a fissure in the left parietal running parallel to and about an inch from the sagittal suture. The scalp was thoroughly washed with perchloride lotion. A flap was reflected from the middle line, passing through the two wounds anterior and posterior so as to completely expose the gashes in the parietal bone. The fracture in the anterior part extended to the dura mater and a fissure passed upwards from it to the sagittal suture. Fearing that the inner plate might be splintered or inverted in spicules a portion of bone, after reflecting off the periosteum,

<sup>1</sup> The cases were shown to the members of the Clinical Society, Manchester.

<sup>2</sup> THE LANCET, vol. i. 1892, p. 1186. *Ibid.*, vol. ii., p. 902.

was removed by the trephine along the posterior edge and the out in the bone thoroughly examined. Hairs were found embedded in the wound and a large clot of blood between the dura mater and the skull. There was no inversion of the inner plate and no splintering, except the fissure already mentioned, as proceeding to the sagittal suture. With a cutting chisel the edge of the gash was planed and cleared of all loosened and contused particles and all foreign matter, and the clot carefully washed out from the bottom of the wound. The fissure was left alone. The gash on the posterior aspect of the parietal was also explored. After trephining, as, in the first case, it was found to be less severe than the one in front, there being no fissure and no clot between the dura mater and the bone. The edges here were also planed and cleared of all débris and foreign matter. The gash in the occipital bone did not penetrate to the dura mater, and, considering the tough, non-brittle character of the bone, as shown by the trephining in the parietal, the edges were simply planed and cleared of all débris. The wound was carefully washed and then sutured; the other flesh wounds were washed and treated. The pieces of bone removed by the trephine, which had been kept in warm antiseptic lotion, were replaced and the periosteum carefully spread over them; the parietal flap was put in position and secured by four or five sutures just to secure coaptation, and loose enough to allow exit for oozing if it occurred in excess. After emptying much perchloride lotion through below the flap and over all the external wounds, iodoform was freely sprinkled over the wounds; then strips of iodoform gauze and then absorbent wool pads all over the scalp, which were firmly secured by bandages and strapping. The patient was put to bed and did well until the tenth day, when she complained of headache, and her temperature rose to 101°. Dr. Tytler was sent for. He removed the dressings and found all the wounds healed by first intention, but there was tenderness near the site of the wound on the posterior part of the parietal. Here the skin of the scalp had been much contused, and though it had been soaked with antiseptics it was feared it had not been rendered aseptic. It would have been better to have pared the lacerated edges. The wound was reopened near the painful spot and a little pus let out, and after lightly syringing the wound a small drainage-tube was inserted. Next day the temperature was normal and continued so. A sinus remained discharging pus. On probing this sinus bare bone could be felt. In this condition the patient left the hospital on June 1st, but to attend as an out-patient to have the wound dressed. Dr. Tytler was waiting for the sequestrum to separate. On Aug. 6th, there being no signs of healing, the patient was readmitted; and had the sinus laid open. It was then found that the posterior reimplanted circle of bone was loose, so it was removed and the sinus healed forthwith. The patient has remained well since.

**CASE 3.**—This case was like the first. The patient, aged eleven years, was admitted on July 11th, 1892, with a compound depressed fracture in the middle of the right side of the frontal bone caused by a blow from a swing-boat. Proceeding as in the first case, a flap was raised and the fracture exposed. A rounded piece of bone about the size of a sixpence had been driven directly inwards so that it lay at the bottom of a pit about three-quarters of an inch deep. Reflecting the periosteum a V-shaped notch was cut in the upper part of the opening with the bone forceps and the bevelled edges were clipped away with the same instrument, for it was found that a larger surface of the inner plate than of the outer had been broken off. Introducing a small forceps at the notch the fragment was seized and removed and put in warm lotion. There was no wound in the dura mater, though it had been considerably depressed by the fragment. After removal the depression was quickly obliterated by a swelling up of the whole surface till it reached the level of the inner plate, but there was no pulsation of the brain to be seen or felt. There was evidently a large meningeal hæmorrhage. There were no symptoms of compression either before or after. The bone was replaced and the wound dressed as in the former cases. The patient was put to bed and did well. The dressing was removed about eight weeks afterwards, and it was found that the wound had healed everywhere. The patient was discharged on Aug. 11th, 1892.

*Remarks by Dr. TYTLER.*—A great deal of the success in these cases was due to the prompt manner in which the wounds were rendered aseptic immediately on admission of the patients by the house surgeons, Messrs. Worboise, Bentley and Williamson. There was no drainage-tube used, and the wounds were left unsutured at certain places to allow of drainage if

it should be required. Paring the contused wound is, I think, excellent, and if freely pared it would provide an easy channel for drainage if not too tightly sutured.

### TORBAY HOSPITAL, TORQUAY.

A CASE OF IMPACTED CALCULUS BEHIND A STRICTURE OF THE URETHRA; RETENTION AND EXTRAVASATION OF URINE; OPERATION; RECOVERY.

(Under the care of Mr. F. T. THISTLE.)

THE complication of calculus of the bladder with a stricture of the urethra is occasionally met with, and the dilatation of the urethra found behind a chronic stricture facilitates the passage of a small stone into the pouch thus formed. After it has gained entrance into this dilated part the occurrence of ulceration and its escape through the opening into the tissues outside are to be expected. How long one or more of the stones in this case had been in the cavity below the urethra it is not possible to say, but instances are on record of their formation in such pouches. Erichsen points out that although mostly renal in origin they may be formed in the urethra, but in other instances appear to have been formed in a pouch lying to the outside of the passage and connected with it by a small aperture. He removed a stone consisting of triple phosphates and weighing an ounce from a point between the urethra and the symphysis pubis; the patient suffered from a tight stricture. As the evidence showing the point of origin is chiefly derived from a chemical analysis of the calculus, it would be interesting to have a report from Mr. Thistle of the composition of the other calculi removed. For the notes of this case we are indebted to Mr. A. E. Watson, house surgeon.

A man aged thirty-two was admitted into the hospital on the morning of Aug. 29th, complaining of pain and swelling in the perineum and inability to pass his urine. He was a short, dark-haired man, fairly developed, but with an anxious expression and somewhat sallow complexion. He stated that he had gonorrhœa in 1877, and in 1889 an operation for stricture was performed at St. George's Hospital. He passed a No. 5 catheter after this until six weeks ago, but was then unable to get one in. For the last three months he has suffered from a sharp cutting pain at the "neck of the bladder," worse on passing urine, and sometimes the stream suddenly stopped. He was unable to pass urine two days before admission, and on the day before (28th) his perineum became swollen and painful.

On examination an elongated, brawny swelling was seen and felt in the middle line of the perineum, and about the centre of the swelling fluctuation could be made out. There was marked tenderness, but no redness of skin. The scrotum and penis were much swollen; no urine had been passed since the day before admission, when a little dribbled away; a catheter could not be passed. The patient was put under an anæsthetic in the afternoon and a longitudinal incision was made in the middle line of the perineum over the fluctuating portion of the swelling; a stream of urine, mixed with pus, gushed out. On introducing the index finger into the wound a hard, smooth stone could be felt (this weighed ninety-one grains, and was a smooth uric-acid stone), which was withdrawn with small forceps, and on reintroducing the finger two more stones could be felt lying in a pouch, formed partly by the dilated urethra and partly by an abscess cavity. The pouch was very large, and extended into the perineum and backwards behind the neck of the bladder. It contained, besides the stones, pus and urine and several sloughs, and its walls were rough and sloughy. The second stone extracted resembled the first, and weighed 124 grains; the third was oval, weighed 425 grains, and was found at the back of the pouch behind the neck of the bladder. It had to be extracted with lithotomy forceps. A sound was then guided into the bladder, but no more stones could be found. Free incisions were made into the scrotum, penis and sides of the perineum, and a large quantity of decomposing urine was let out. A tube was introduced through the perineal wound into the bladder and another in the perineal pouch. A dressing of blue wool, absorbent wool and tenax was then applied, and the penis and scrotum were frequently fomented with warm iodoform. A morphia suppository (1½ gr.) was ordered. The patient's general condition was very bad for two days after this, but on Sept. 2nd the following note was made: Patient much better this morning; slept well. Pulse 100; stronger and fuller. Takes nourishment well. The perineal wound is looking

well, suppurating freely; the pouch is filling up. He passes urine freely through the perineal wound. The incisions in the scrotum and penis are healing rapidly. Temperature normal. On Sept. 24th a No. 1 silver catheter was passed through the stricture after some difficulty, the patient being under an anæsthetic. The catheter was guided into the bladder (by the finger introduced through the perineal wound) and tied in. The stricture was gradually dilated, and on Oct. 22nd the edges of the perineal wound were pared and stitched with silver wire. The surrounding tissues were so indurated that the wound would not unite. The patient is now in very good health, he passes urine through the perineal wound three or four times daily, and has little or no trouble from his urine dribbling through the wound.

*Remarks by Mr. THISTLE.*—The case is an unusual one, and the impaction of a stone behind a stricture is seldom a cause of extravasation of urine. The perineal pouch was most probably formed by the dilated urethra behind the stricture and the walls of an abscess. The third calculus was found at the back part of this pouch and behind the neck of the bladder. With regard to the stricture, it was situated about the bulbous portion of the urethra, and although no catheter could be passed when the patient was admitted, one was passed some weeks after, when the parts had been kept at rest and all element of spasm had disappeared. The wounds in the scrotum, penis and perineum healed very rapidly, although the tissues had been saturated with putrid urine.

## Medical Societies.

### MEDICAL SOCIETY OF LONDON.

#### *Cholera.*

AN ordinary meeting of this Society was held on Dec. 5th, the President, Mr. Hutchinson, being in the chair.

Surgeon-Colonel J. B. HAMILTON read a paper on Cholera, its Epidemic Progression and Causation. He explained the number of conflicting theories of the causation and spread of cholera by each observer reasoning on the facts that had come to his personal knowledge. The statistician surveyed the various outbreaks from his office and mapped out the progress of the disease. He alluded to the curious want of unanimity in the writings of Indian authors which had discredited Indian opinion on this subject. The object of the paper was to show that no theory hitherto propounded covered the ground of epidemic cholera, the explanation in every case falling short in some material particular. There were three principal theories: (1) propagation by drinking water, food &c.; (2) human intercourse; and (3) conveyance of the disease by the air, to which might now be added the so-called vibrio or cholera bacillus. He assumed that the identity of the disease as met with in Asia and Europe respectively was now established and he thought that its progression also took place on much the same lines. Here as there it followed certain well-defined lines, was more virulent at the commencement than at the close of an epidemic (thus accounting for the successes claimed for so-called specifics) and it did not retrograde or work backwards. Admitting the contaminated water theory for the sake of argument, he raised the question as to the value of filtration, expressing grave doubts as to the efficacy of any system of water filtration as carried out by the water companies. He called attention to a paper by the State geologist for New Jersey on the plan of precipitating the organic matter of water by the addition of two grains and a half of alum to the gallon and subsequent filtration. He asserted, on the authority of an eminent bacteriologist, that cholera had never been proved to be one of the diseases conveyed by bacilli. Koehel believed that the disease was conveyed by the bacillus, but many other authorities, after mature consideration, had come to a directly opposite conclusion, and he referred to some of the examples mentioned by the dissenters in support of their view. He denied that the diminution of cholera in Calcutta that had followed the introduction of a supply of pure water was due directly to the purity of the water. The effect of a pure water-supply on the general health would account for a large share of the diminution apart from the absence of specific contamination. The case of Fort William, where the mortality fell from 20 per 1000 to 1 per 1000 on the introduction of a better water-supply, could not be accepted as certain

proof that the improvement was entirely due to the better water-supply, because at the same time general sanitation was also much improved, notably by the erection of spacious barracks and the use of earth closets. He referred to the outbreak of cholera in the great Alipore gaol which followed the introduction of the pipe water, and he claimed that it was as fair to put this to the account of the water as it was to attribute all improvements in the mortality returns to that cause. He traced the course of epidemic cholera in India, showing how the heavy rainfall extinguished cholera in Lower Bengal and how with the monsoon it advanced up the valley of the Ganges or Bramaputra or both. He urged that this fact was evidence in favour of the air, plus heat and moisture, being the chief factor of progression. He admitted, however, that instances were on record of the cholera progressing in the face of the monsoon. In 1878-79 the disease left the endemic area and advanced to Oude, the following year it spread over the Punjab on to Cabul. During the epidemic in the north-west in 1878 large numbers of natives went by rail from the infected districts into the Punjab, many dying on the way, yet the disease never became epidemic there during 1878 and did not break out in the non-infected districts. The same thing occurred the following year, when the Punjab in its turn had become an infected district. Cholera then went up rivers and refused to ignite in uninvaded districts or in districts over which it had traversed. He mentioned several instances within his own experience of cholera breaking out under circumstances in which the water-supply could not well be suspected. He asked how it was that cholera sometimes attacked European barracks while the filthy native bazaars close by with a filthy water-supply escaped. He maintained that observation and experiment tended to prove that the comma bacillus could not determine cholera unless there was some other factor present in addition. He insisted that cholera was not infectious or contagious in the ordinary sense; indeed, the wards of a cholera hospital seemed to be about the safest place to live in during a great epidemic. He referred to an outbreak at Allahabad last year which occurred quite suddenly and without any adequate explanation, and he observed that the period of incubation appeared to be not longer than three days. In reference to the transmission of cholera by the air, he referred to the remarkable instance of two hill stations, separated by a deep valley and at a distance of fifteen miles, in which cholera broke out and ceased on the same days, the intervening country remaining free. Admitting that much still remained to be learned in respect of this disease, he characterised quarantine as impracticable, useless and vexatious. He insisted upon the importance of evacuating infected dwellings forthwith, a measure which he considered as even more important than the removal of the patients themselves. As a disinfectant he recommended crude sulphate of iron in preference to dangerous substances such as corrosive sublimate. He concluded with the suggestion that the first opportunity should be taken to try the effects of the transfusion of the blood of the goat directly into the veins of the patient in the algide stage.

The PRESIDENT said that he had had a good deal of experience personally in dealing with cholera, especially in the epidemic of 1846. He was one of the earliest converts to the water theory of Dr. Snow, and all his experience since then had tended to confirm his conviction of the truth of that doctrine.

Dr. MACLEOD of Allahabad referred to the fallacy of dealing with this subject from its general aspect. As to its incidence, it was accidental rather than general, both as regarded communities and places; its mode of progression was also peculiar—going by leaps and starts and travelling in zigzags or forwards and backwards. To use general terms such as waves and areas to describe epidemics was only to add confusion to the subject. So long as the data remained imperfect, so long would any general statement formed on those data be imperfect also.

Dr. SIMPSON of Calcutta said that the conflicting views in regard to cholera which obtained in India and Europe were due to the different methods of investigation adopted. An outbreak in England was succeeded by a local investigation, followed afterwards by statistical evidence; but in India, owing to its immense size and the paucity of medical men, the local investigation was either not conducted at all or was very imperfect, and a statistical statement was relied on in its place. All his experience pointed to the fact that when a careful local investigation had been made the cholera

which had come from a healthy to an infected district was found to have been spread chiefly by contaminated water, milk and food, together with bad drainage. As to the cholera which followed in the wake of the Hurdwar fair, its greater spread in a northern and western direction was due to the fact that the vast majority of the pilgrims came from those directions and returned thither; out of a million present at the fair only about a thousand came from Bengal. There was abundant evidence that the disease spread from a centre of infection; it travelled towards China in the east and towards Europe in the west. In Calcutta a festival was held once every twenty-seven or thirty years, called the Ardhodaya Jog; on the last occasion of its meeting cholera broke out and caused a great mortality at a time when it was unusual for cholera to be prevalent in Calcutta. Though it might be true that no exclusive doctrine would explain all local outbreaks, yet certain media were more likely to be contaminated by cholera poison than others; and in India the medium most commonly contaminated was water. Calcutta, Lahore, Delhi, Nagpoore and Bombay all bore witness to the truth of this; since they had acquired a pure water-supply they had been no longer so subject to epidemics of cholera. The Dutch in Batavia remained free from it, owing to their system of artesian wells; so also in Pondicherry, Rangoon, Colombo, Candy, Singapore and other Eastern towns. The outbreak at Damietta in 1883 was distinctly due to contaminated water.

Mr. E. HART welcomed the remarks of the last speaker, remarking on the value of such a series of affirmative facts connecting a defective water-supply with cholera outbreaks. He had never previously been able to find any light from communications from India on this subject; the reports revealed as a rule nothing but confusion, due in part to the extraordinary difficulties attending the investigation of the disease and in part perhaps to administrative pressure which had been brought to bear on the writers of the reports. Surgeon-Colonel Hamilton had really only enumerated two theories as to the spread of cholera, by water and by air, and as to the latter, the course of his remarks showed that he had totally abandoned it. Cholera certainly did not travel with the air across Europe; the rate of its progress corresponded exactly with the rate of human intercourse. For his own part he believed that water, and water only, was adequate to explain it, and the evidence to prove this was now overwhelming.

Mr. MACNAMARA referred to his experience at Fort William, and said that he had always insisted on the necessity of a pure water-supply. This was provided, and between 1863 and 1873, though cholera prevailed around to a great extent, the mortality in the Fort was extremely small. The monsoons had a great effect in the spread of cholera, for they blew up the rivers small craft, loaded with passengers, who traded with the settlements up the river, and these passengers carried the cholera up with them.

The PRESIDENT having remarked on the extreme importance of the water being boiled by individuals before consumption,

Surgeon-Colonel HAMILTON briefly replied. He said that though he did not deny the enormous value of good water, or the injury caused by bad water, there was something in addition to this which was present to explain the phenomena. He remarked on the difficulty of proving any one theory to the hilt, and said that if the question of water-supply was the sole one, how was it that British troops in perfectly clean barracks with a good water-supply suffered, when within a quarter of a mile the natives in a bazaar would escape, although the water they consumed was filthy?

## PATHOLOGICAL SOCIETY OF LONDON.

*Myxoma of Humerus undergoing Chondrification.*—*Fibroma of Male Breast.*—*Chronic Mastitis of Male Breast.*—*Hyaline Fibroma of Cow's Udder.*—*Fatty Tumour from Lip.*—*Histology of Yaws.*—*Sarcoma of Sterno-mastoid.*

An ordinary meeting of this Society was held on Dec. 6th, Sir George M. Humphry, President, in the chair.

Mr. EDGAR WILLETT showed for Mr. Howard Marsh a Myxoma of the Humerus which was undergoing chondrification in places and had involved almost the entire shaft of the bone. The limb was removed from a female fifty-four years of age, and the duration of the growth was under one year.

Mr. C. F. BEADLES showed a Fibroma of the Breast

removed from a man aged thirty-four, who entered the Cancer Hospital in May, 1891. The tumour, which was of the size of a small walnut, was hard and movable; it lay at the back of the gland imbedded in the pectoral muscle. There were no enlarged glands in the axilla. On microscopic examination it proved to be a pure fibroma without epithelial elements.

Mr. W. ANDERSON showed a specimen of Chronic Mastitis from a man aged thirty-five. The gland began to enlarge six months before the patient came under observation. It commenced without apparent cause and was gradual and painless in progress. It was hemispherical in form, about an inch and a half in diameter at its base, moderately hard to the touch and slightly tender. It was removed at the end of May, 1891, and was found to consist of new fibrous tissue developed around the elements of the gland. Under the microscope the ducts and acini presented no especial change, but around each duct was a distinct area of proliferation, and beyond this the new fibrous tissue was arranged concentrically. The patient was still quite well, but it was worthy of remark that the scar underwent a cheloid hypertrophy. Chronic mastitis in the male in later life was not specifically referred to in text-books, but it appeared to supply a missing link in the pathological analogies of the male and female mammae, completing the series of evolutionary reactions exemplified in the mastitis neonatorum and mastitis of puberty so well known in both sexes by furnishing a counterpart to the climacteric mastitis of women. The tendencies of the condition were doubtful, whether towards resolution, cirrhotic contraction or malignant degeneration.

Dr. DUDLEY COOPER showed a Tumour which had been removed from the Udder of a Cow. It was of the size of a horse chestnut, hard, freely movable and situated close to the base of the left posterior teat. Microscopically it consisted of dense fibrous tissue, with very few cellular elements, the latter being seen chiefly at the periphery: towards the centre the growth presented a hyaline appearance. He could find no record of a similar specimen.—The PRESIDENT referred to the importance of keeping clear the distinction between tumour and inflammatory growth. In tumour the change originated in the mass itself, and continued owing to an absence of the controlling influences of nutrition. An inflammatory growth, on the other hand, depended on some change from without; it could not increase, though it might be increased. From the structure of the male breast, fibroma rather than adenoma was to be expected there.

Mr. W. EDMUNDS showed a specimen of Fatty Tumour of the Lip, which was situated on the inner and left side of the lower lip. It was nearly spherical and about an inch and a quarter in diameter. It lay immediately under the mucous membrane which was stretched over it, but not ulcerated. On microscopic examination the tumour proved to be a lipoma. Adenomata within the lip were well known, but he had found no mention of a fatty tumour in this situation.—The PRESIDENT remarked that lipomata were seldom seen in places where adipose was mingled with fibrous tissue, as in the palm or sole, but were more likely to occur where fatty matter formed a greater component of the tissue, as in the back or in the shoulder.

Mr. J. JACKSON CLARKE showed for Dr. Beaven Rake specimens of Yaw Tubercles, some of which had recently developed while others were subsiding. Dr. Rake sent with the specimen some interesting observations which he had recently made. He had been using as a cultivating medium ascitic fluid and human serum mixed with glycerine and gelatine. Most of his specimens had been obtained from lepers, although the local growths showed no leprosy bacilli. Although he could find common pyogenic cocci on the surface of the tumours, he could discover no specific cocci in their substance which on inoculation would produce yaws.

Mr. J. J. CLARKE also read a communication on the histology of the Yaws Tubercle. He compared it to a syphilitic mucous tubercle, and referred to the observation that the disease might be an effect of climate on syphilis, which Mr. Hutchinson considered possible. On section the epidermis was found raised up, there was an overgrowth of papillæ and leucocytes which had accumulated beneath the epidermis. Though the specimens had been obtained from coloured people, the tubercles had become totally deprived of pigment. The rete cells were completely divested of this substance, which was found collected in the branched connective tissue cells beneath the epidermis in the papillary layer of the corium. In older tubercles the branched cells had disappeared and the pigment was absent, but in the healed tubercles the skin became again

hyper-pigmented as in the old lesions of syphilis. These phenomena appeared to resemble the flux and reflux of pigment to and from the frog's epidermis.—Mr. HULKE had seen about six cases of yaws, all in blacks, who had come hither from the West Indies. He had been unable to satisfy himself, in some of them at any rate, that the patients had suffered from syphilis. Microscopically the structure resembled granuloma; some of the tubercles ulcerated, whilst others underwent atrophy. In none of his cases was leprosy present.—Dr. COLCOTT FOX described the appearances seen in Yaw Tubercles younger than those shown, which had been sent to him by Dr. Rake. The appearances were precisely those described by Mr. Clarke. Though many accounts of the disease read like syphilis, yet authorities in charge of yaws hospitals stated that the disease was distinct. It was easily inoculable, the mucous membranes might be affected, and in ill-nourished people tertiary symptoms followed, with nodes and gummata. Yet women suffering from yaws were delivered of children showing no sign of syphilis, and people who had had syphilis would readily contract yaws afterwards. Dr. Charlovis of Java had stated that he had satisfied himself by experiment that syphilis and yaws were distinct. It was interesting to note that in Africa parents commonly inoculated their children with yaws, because in youth the disease was milder.

Mr. W. ANDERSON related a case of Sarcoma of the Sterno-mastoid from a female infant aged thirteen months. The patient was suffering from an ovoid tumour about the size of a large walnut, involving the whole length of the muscular belly of the right sterno-mastoid. The growth was of seven months' duration, its evolution slow and painless, and giving rise to no lymphatic affection or constitutional disturbance. The family and personal history of the child were negative. The growth was diagnosed as a spindle-celled sarcoma, and was excised with the whole of the muscle on Oct. 8th last. It was not encapsuled, and required careful dissection from the carotid sheath. On section it was found to consist entirely of spindle cells and to replace the whole of the muscle except a few fibres of the cleido-occipitalis. The child made a good recovery, and at present there was no tendency to wryneck. The case appeared to be the first on record of a sarcoma of the sterno-mastoid, but a like growth was known to have occurred in other muscles. One in the sartorius was referred to by Mr. Erichsen, and here the removal was followed by recurrence.

The following card specimens were shown :—

Dr. F. G. PENROSE: Cirrhosis of Liver in a boy of sixteen.

Dr. E. C. PERRY: Papilloma of Duodenum.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### PATHOLOGICAL SECTION.

*Traumatic Malignancy.—Actinomycesis.—Aneurysm of Aorta.*  
*"Walking" Typhoid Fever.—Typhoid Bacillus.*

A MEETING of the Section of Pathology was held on Nov. 4th, Dr. E. H. Bennett in the chair.

Dr. GRAVES showed for Dr. WHEELER a specimen of Diseased Knee-joint removed from a young man under twenty years of age, who hurt his right knee by falling against a granite stone support when endeavouring to leap a chain. Although he suffered intense pain from the injury he did not seek advice until April (of this year), at which period his knee-joint was circumferentially half an inch larger than his sound joint, caused by effusion; besides, there was a marked circumscribed enlargement upon the inner and upper part of the tibia, just below the articular surface. The effusion into that joint subsided under treatment, the tibial growth rather increased, and was followed by slight glandular enlargement, situated in and corresponding to the saphenic opening. Amputation was performed at the lower third of the thigh and the stump healed. The enlargement in the groin region was not removed at the time of the amputation; it, however, increased in size as the patient convalesced. Removal was advised and recovery ensued. The new growth in the head of the tibia was an osteo-sarcoma; the gland from the groin was infiltrated with osteo-sarcoma. The gland was regarded as especially interesting, as sarcoma does not generally spread by the lymphatics. Probably the

gland became affected from the femoral vein. The growth evidently started in the periosteum.

Dr. SCOTT showed a case of Actinomycosis which was found by Sir Charles Cameron in a cow slaughtered in the Dublin abattoir and which is the first case described from Ireland. He gave a summary of the history and of our present knowledge of the disease in the domestic animals and men. The summary was illustrated by microscopical sections of the Irish case and sections of other Scotch cases sent by Professor M'Fadyean; also micro-photographs of the principal features in the sections were shown by the optical lantern.

Dr. J. W. MOORE showed a specimen of Aneurysm of the Aorta opening into the Left Lung and Pleura. The patient, a man aged fifty-seven, had suffered from aortic valve disease and chronic aortitis. He died of hæmorrhage after a series of convulsive seizures. The left pleura was filled with blood; the left lung had been torn by a blood stream which had escaped from an aneurysm of no great size in the descending aorta at the level of the fifth and sixth dorsal vertebrae, the bodies of which were eroded, leaving the intervertebral disc projecting between them.

Dr. J. W. MOORE showed a specimen of extensive Ulceration of both Agminate and Solitary Glands of the Ileum in the case of a patient aged twenty-nine, who died on the ninth day of enteric fever, with symptoms of delirium tremens, terminated by a violent convulsive seizure. The patient had walked about until within thirty hours of his death. Characteristic lesions of enteric fever were found in the ileum for a distance of no less than seven feet from the ileo-cæcal valve—the Peyer's patches near the valve being ulcerated, while those higher up in the gut were still in the stage of *engouement*. The mesenteric glands were swollen and soft. There was considerable enlargement of both liver and spleen.

Dr. M'WEENEY showed the intestines from two cases of Enteric Fever that had occurred during the previous week at the Mater Misericordie Hospital. The clinical course of these two cases had been signalled by the predominance of unusual symptoms, tending to make the diagnosis a matter of doubt and difficulty. The first case was that of a female aged nineteen, who was admitted to hospital unconscious and with a high temperature. She lived for four days, but never at any time recovered consciousness. At the necropsy the only morbid appearance found in the course of a complete examination was uniform swelling of the agminated and solitary follicles of the intestine, with some slight ulceration near the ileo-cæcal valve, enlargement of the spleen and great enlargement of the mesenteric glands. The second case was that of a man aged twenty-eight, who had died after a few days' very severe fever, covered with a rash exactly similar to that of exanthematic typhus. At the necropsy the spleen was but slightly enlarged, but the mesenteric glands were considerably swollen and so were Peyer's patches. Cultures had been made in each of these cases from the spleen and pericardial exudation, but as they had been made only on the previous day—that on which death had occurred—the cultures, though visible under the microscope, were as yet hardly to be seen with the naked eye. Dr. M'Weeny expressed the opinion that in future two separate categories of enteric fever would have to be discriminated—one due to the typhoid organism, the other to Eberth's bacillus.

### SURGICAL SECTION.

#### *Estlander's Thoracoplasty Operation.*

A meeting of this Section was held on Nov. 11th, Mr. Hamilton, President, in the chair.

The PRESIDENT read an address alluding to the various surgical advances that had of late years occurred, and spoke of anaesthesia, antiseptics and vivisection.

Sir W. STOKES made a communication on Estlander's Thoracoplasty operation. After some preliminary remarks on the great advances that have been made in recent years in thoracic surgery, he dwelt on the causes that have of late been chiefly instrumental in enabling surgeons to get better results in the treatment of empyema than formerly, these being mainly antiseptic practice and the adoption of thorough and methodical drainage. He discussed the cases in which drainage would be likely to be sufficient and those in which something more was required, and the question as to whether thoracoplasty should be regarded as only suitable and restricted to chronic fistulous empyemata, and the cases that have frequently been tapped, or whether it ever should be adopted as a primary operation.

He then spoke of the various lines of incision recommended by Estlander and others, but considered that a more important matter was to determine the point where the opening into the cavity of the pleura should be. The views of Mr. Godlee and Mr. Heuston were considered, Sir W. Stokes being of opinion that the situation recommended by them would be, in the majority of instances, too near the diaphragm. The question of flushing the pleura was also discussed, he giving his approval to the practice both during and subsequently to the operation.

Mr. HEUSTON said that Estlander's operation was only required in cases of very long standing, where the conditions as mentioned by Sir W. Stokes existed, and gave rise to a space which could not be occluded unless the chest wall were allowed to adapt itself to the collapsed lung. In the performance of the operation it was important that the periosteum of the rib should not be preserved to a great extent, as it was liable to form new bone to such a degree as to do away with the object of the operation. In the more recent cases operated on by Mr. Heuston he turned the flap of periosteum over the end of the rib where it had been cut across, and thus hindered the absorption of the discharge by the cancellous bony tissue, to which he ascribed the immunity of his patients from pyæmia, which some authors consider the greatest danger from this operation. The only point in the paper with which he (Mr. Heuston) was not inclined to agree, was in the utility of frequent washings of the pleural cavity; and always, in recent cases, he employed only one washing—viz., at the time of the operation, to remove any semi-solid lymph which might be within the pleural cavity.

#### MEDICAL SECTION.

##### *Lead Poisoning.*

At a meeting of this Section held on Nov. 18th the PRESIDENT (Dr. W. G. Smith) made a few introductory remarks, in which a retrospect was given of the work which had engaged the attention of the Section during the last session.

Dr. O'CARROLL then related the history of four cases of Cerebral Lead Poisoning, one of which was fatal. Two non-fatal cases occurred in civil servants who used lead-containing hair dyes. One of these, aged about sixty-two, had a slight hemiparesis, which passed away in a couple of days and recurred in about a fortnight. There was also some visual amnesia and some amblyopia. On discontinuing the use of the hair dye all the symptoms gradually disappeared. The other case was much more severe. The patient had, about once every three months during a period of three years, attacks of violent headache, coma, delirium and sometimes slight convulsions, followed, as a rule, by a period of insanity. The coma lasted from one to six days, the insanity from one to six weeks. The delusions on some occasions were of the grandiose character commonly associated with general paralysis of the insane. The case was from time to time diagnosed as cerebritis, diffused meningitis, general paralysis, and even on some occasions hysteria. After the patient had suffered thus for two years it was surmised that the symptoms must be due to some cause operating regularly from outside, and a hair dye found to contain lead was fixed upon as a possible source of trouble. From the date of the disuse of the hair dye the patient's symptoms underwent a gradual involution. The coma never appeared again, the headache gradually became less frequent and severe, the mental condition became for a time melancholic and then returned to normal health, and he is now, nine years after his first attack, in perfect health. One morbid condition alone remains—namely, that he gets occasional attacks of *petit mal*, from which he never suffered till this illness. The fatal case was that of a plumber who had been in good health up to about three months before death. He at first showed slight mental peculiarities, had headache, and was forgetful. Severe symptoms began with an epileptiform attack, followed by spasmodic contractions of the muscles of the right side, repeated sixty times a minute, with right hemianopia. The mind remained pretty clear, but there was total loss of the sense of personal localisation. In another fortnight he had epileptiform convulsions during about twenty-four hours, followed by partial paresis of the left side. Finally he died in a further attack of frequently repeated convulsions. At the necropsy the arachnoid was seen to be somewhat distended with fluid, so that the cerebral fissures seem to be occupied by cylindrical or spherical cysts. On removal of the arachnoid, after hardening in

Müller's fluid, the convolutions were found separated by wide fissures, while at various parts portions of the convolutions were depressed or apparently punched out. In the spinal cord a somewhat similar condition obtained in the lower dorsal region, where the main strands of fibres seemed partially separated from one another by a dissecting sub-arachnoid effusion. Professor Lapper found lead in the liver, the kidney and the spinal cord. Dr. H. C. EARL made an examination of the brain cortex at one of the convolutional depressions and reported the presence of a curious black pigmentation of the neuroglia cells and a similar staining of the neighbouring capillaries; this staining involved only part of the sections.—Dr. FALKNER said that the principal substances which were used in hair dyes were nitrate of silver, pyrogallic acid and acetate of lead with sulphur. He had discovered that nitrate of bismuth—a body insoluble in water owing to the formation of the subnitrate—was soluble when rubbed up with glycerine. This substance dyed hair a rich black.—Dr. H. C. TWEDDY thought it remarkable that the patient who stopped using the hair dye in 1886 should up to the present have occasional mild attacks and that the poison should have taken such a length of time to be eliminated.—Dr. QUINLAN said he had seen a case like one of Dr. O'Carroll's. In this case infection was caused by the use of a lead comb and the symptoms disappeared after the comb ceased to be used.—The PRESIDENT mentioned two cases which had come under his notice. In the first case saturnine symptoms were present. The patient was a manufacturer of sugar sticks and he used chrome yellow in preparing them. Thus the introduction of lead into his system was accounted for. The second case was that of a man who had become incapacitated for his duty and who was pensioned on account of a diagnosis of lateral sclerosis. Dr. Smith noticed he had a blue line on his gums. He also found out that the man had a habit of constantly chewing a pellet of lead. Slow absorption took place, and he developed spinal symptoms. He was treated with iodide of potassium and magnesium sulphate, and got well. Dr. O'Carroll, in his paper, made no mention of the spinal cord or the peripheral nerves being affected. Lead and other elements of high atomicity—such as silver, mercury and arsenic—are very poisonous to the nervous system; they act as protoplasmic poisons. Silver and lead are in many respects analogous. Both form dense albuminates with the tissues, but there is this point of difference—the silver albuminates are insoluble in chlorides and also in lactic acid, while the lead albuminates are soluble in the alkaline and acid fluids of the body. On account of this lead poisoning is more easily caused. The lead is a direct protoplasmic poison, and a little metallic poison does a great deal of mischief in the brain. Of late years a certain quantity of lead has been in some cases abstracted from the cerebrum and cerebellum. The metal forms a direct combination with the albumen. Another proof of its direct action on the nervous elements is shown by histological examination, which reveals certain pigmentary changes. In addition to this, there are certain bad effects on the general health. These two things are sufficient to account for the seriousness of the phenomena and also for their instability witnessed in cases of lead-poisoning. As regards treatment, iodide of potassium does no real harm by increasing the solubility of lead already deposited in the system. The quantity is very small and the increased quantity in solution for a couple of days would not signify. Lead is not excreted by the kidneys to any practicable extent, but it is excreted by the intestines, and it is very liable to be re-absorbed. Consequently, it is always well to combine with the iodide of potassium a saline purgative, such as magnesium sulphate.—Dr. O'CARROLL made a few observations in reply and the section adjourned.

GLASGOW MATERNITY HOSPITAL.—The directors of this hospital state in their report that the revenue has failed to meet the expenditure, owing to which fact the much desired extension of the premises has been delayed, the deficiency in the revenue having to be made up from the capital fund. No donations have been received during the year. The number of patients attended to at their own homes was 1635, and at the hospital 388. The total number of cases attended shows an increase of 104 over that of last year. The Lord Provost, in moving the adoption of the report, said that the financial state of the hospital was such that, if it continued for another three years, the whole of the capital fund would be exhausted. The report was adopted.

## Reviews and Notices of Books.

*An American Text-book of Surgery for Practitioners and Students.* Edited by WILLIAM W. KEEN, M.D., LL.D., and J. WILLIAM WHITE, M.D., Ph.D. Profusely Illustrated. Philadelphia: W. B. Saunders. 1892.

THIS work has been produced by thirteen of the most eminent teachers and practitioners of surgery in the United States of America, but the plan pursued has been a distinct advance upon the method employed in this country when several authors combine to publish a single volume. Instead of each author being alone responsible for the article or articles to which his name is attached, "the entire book has been submitted in proof sheets to all of the authors for mutual criticism and revision. As a whole, the book may therefore be said to express upon important surgical topics the consensus of opinion of the surgeons who have joined in its preparation." The chapters are accordingly unsigned, and no indication is given of the share taken by any one contributor. This is joint authorship of the best kind, and its success in this instance appears to us to have been so marked that it will probably encourage other editors to adopt it. Its success is shown by the unity of plan and even character of the book throughout. Open it where he will the reader notices the same features in the design and the same limitations and peculiarities. The great aim of the authors has been to present the latest developments of surgical theory and practice. Attention is given chiefly to that which is new both in pathology and treatment. A great deal of detail to be found in other surgical text-books is omitted here, or very briefly noticed, while Bacteriology and the details of Aseptic and Antiseptic Surgery receive much attention. This is the great merit of the book. The pathogenic bacteria are well described and figured, and the present position of the science of bacteriology is clearly stated, whilst its well-grounded conclusions are accepted fully and frankly. In the same way, the basis of the therapeutics advocated is a confident belief in the antiseptic treatment. On this the authors speak with no uncertain sound: their faith in it is strong and intelligent and it is the outcome of experience gained from a scrupulous observance of all the minute details of scientific asepsis. It has often been said that antiseptic surgery is only the adoption of cleanliness, and the unobservant have thought that modern antiseptic surgery depends less upon the observance of minute detail than the older practice, when so much stress was laid upon the spray. A careful perusal of the chapter on the proper conduct of an operation will dissipate both these views, and will demonstrate how highly scientific and how exquisitely precise such an operation ought to be. If this text-book is a fair reflex of the present position of the best American surgery, we must admit that it is of very high order of merit, and that English surgeons will have to look very carefully to their laurels if they are to preserve a position in the van of surgical practice.

Having thus expressed our high appreciation of the striking merits of this work we must go on to say that the English reader will miss in it much of the anatomical and clinical detail that he finds in his own manuals of surgery. The writers appear to have been so anxious to present the modern phase of surgical knowledge that they have seemed to ignore much of the learning acquired in other decades and other centuries. We doubt whether this text-book is well adapted for those commencing their study of surgery; it presupposes a good knowledge of surgery, or, at any rate, it will only be appreciated by those who possess such a knowledge. We are anxious to indicate the strong distinctive features of this work rather than to dwell upon details, but we cannot help wondering why adenomata are

grouped among mesoblastic tumours, and we regret the exaggerated faith in the value of large doses of alcohol in many surgical diseases. To an English eye "fiber" and "center" are unseemly; but we are not without hope of the editors, for more than once we find "fibre" has crept in, showing that they have apparently an open mind on the subject.

*Dermic Memoranda.* By WILLIAM GEMMELL, M.B. Glasgow: A. Stenhouse. London: Baillière, Tindall and Cox. 1892.

THE aim of this *brochure* of 116 pages is to give the student the essential facts of dermatology and the diagnosis of the exanthemata. The latter portion of the author's task has been fairly well fulfilled, as might be expected, as he has been a resident superintendent of a fever hospital. Of the former portion we must speak less favourably. It is very doubtful whether "thumb-nail" books of this class, even when accurate, do not give the student as much to unlearn as to learn, dogmatic statements in medicine so frequently requiring qualification. Moreover, it needs no little judgment founded upon practical experience to know what are really the most essential and diagnostic facts to be remembered. The work before us, though not discreditable to a young man, which the author presumably is, exemplifies this, and contains inaccuracies and omissions of important diagnostic points which further experience would enable him to avoid. Thus, in contrasting scabies with eczema pustulosum, he speaks of vesicles as if they were synonymous with pustules, and says that eczema does not often occur on the hands and that itching is absent. Xanthoma nodules are said to be painful, alopecia areata is often hereditary, and psoriasis is spoken of as not being a disease of childhood, and when it occurs on the sole the student is told to suspect syphilis—to say the least of it a misleading way of stating that there is a scaly plantar syphilitic sometimes called "psoriasis." "Bullafe" for *bullous* and "discreet," for *discrete*—the latter occurring too often to be merely a misprint—are only minor faults.

### LIBRARY TABLE.

*Epidemic Skin Disease.* By THOMAS D. SAVILL, M.D. London: H. K. Lewis. 1892. — This is a reprint of the various articles published by the author on the remarkable epidemic or rather endemic disease of the skin resembling either eczema or pityriasis rubra which occurred chiefly in the West-end of London during the summer and autumn of 1891. It contains a coloured plate and several reproductions of photographs, and to those who wish to possess a valuable record of this unprecedented outbreak we can recommend this *brochure* of sixty-four pages, which is well got up in plates and typography and enclosed in a parchment cover.

*The Bacteriological World and Modern Medicine* is doing good work in bringing together abstracts of a number of most important papers that are published on this side of the Atlantic, and at the same time of placing before its readers a number of original articles, especially those written in America. The most interesting and important original articles in the August number are those by Dr. J. H. Kellogg, on the New Chemistry of the Stomach, in which he criticises the work of Ewald and Boas, and Hayem and Winter's "Chemismus Stomachal" (Dr. Kellogg's paper is, however, not completed in this number), and Dr. J. M. Byron's description of an apparatus for cultivating anaerobic bacteria, either in plates or in tubes, which has the special advantage that in it either plates or tubes can be utilised, and they may be removed from time to time for examination. The chief point about this method is that hydrogen is retained in the bell jar by means of a layer of mineral oil. The more interesting translated articles

are Dr. Kitasato's Results of Pure Cultures of Tubercle Bacilli and other Pathogenic Bacteria from Sputum, and that of Professor Dujardin-Beaumez on the Liver as a Bile-making Organ. In the monthly bulletin from the Laboratory of Hygiene, by Drs. Kellogg and Paquin, we find an account of some Experiments on the Relative Influence of Germs and their Products in the Production of Disease, and a continued (illustrated) article on Liver Flukes in Cattle.

*Fever Nursing: a Course of Lectures on the Nursing Required in Cases of Ordinary Fever.* By MARY HARRIS, Matron of the Suffolk General Hospital, Bury St. Edmunds, Member of the Council of the Royal British Nurses' Association &c. London: The Record Press, Limited, 376, Strand, W.C. 1892.—This is a good sample of the Record "Booklet" series. The authoress tells us that the articles originally appeared in 1888 in the *Nursing Record* in a serial form, and that they are republished in consequence of the numbers of the journal in which they appeared being out of print. The nursing and management of the following diseases are dealt with—viz., scarlet fever, typhoid fever, typhus fever, chicken-pox and small-pox; and at the end a couple of pages of examination questions are added. We have been much gratified with our perusal of this little book, which, if it makes no claim to originality, nevertheless contains much sound and useful information well put together. The salient pathological and medical points connected with these fevers, with which every intelligent and educated nurse should be acquainted, are clearly and sufficiently set forth, as well as those points which have a direct practical bearing on the nursing and management of these diseases.

*Aix-la-Chapelle as a Health Resort.* By Drs. ALEXANDER, BEISSEL, BRANDIS, GOLDSTEIN, MAYER, RADEMAKER, SCHUMACHER and THISSEN. The English edition, translated with the sanction of the civic authorities by JAMES DONELAN, M.B., M.Ch., B.A.O. &c. London: J. & A. Churchill. 1892.—This work consists of a general description of Aix-la-Chapelle and its baths, together with a collection of essays by the physicians of the locality. "The baths," we are told, "vary in temperature from 47° to 74° 6' C. .... The douche is always administered in the bath itself. The doucheur or doucheuse enters the bathroom with the patient, and supplements the action of the douche by means of kneading and massage, or moderates the force of the jet with his hand, while he allows it to play in a slanting direction. The patient does not need to go into a separate douche-room, as is the custom in so many other establishments, but he remains some time longer in the bath after the douche in order to assist its action. Vapour baths have been placed in all the bath houses, and are supplied by the natural hot vapours of the thermal waters, which are formed either at the outlet of the lower spring or whilst flowing down in one of the channels fed by the principal spring. .... The vaporised thermal water can also be inhaled by suitable spray apparatus." The second part of the work contains papers on the Treatment of Gout, Chronic Rheumatic Arthritis, Arthritis Deformans, Diseases of the Skin, Injuries and their Consequences, Chronic Catarrh of the Digestive Tract, Chronic Catarrh of the Pharynx, Larynx and Bronchi, Syphilis, Diseases of the Nervous System, Tabes Dorsales, Syphilitic Diseases of Internal Organs, Chronic Metallic Poisoning and Diseases of the Eyes. The translation appears to have been done carefully, though here and there little Germanisms may be detected; and in the list of chemical constituents of the waters we find "iodide of soda," "chloride of ammonia," and "phosphate of soda." These are, however, but mere verbal defects in a very valuable scientific account of one of the most important thermal springs in Europe, which will well repay perusal by any physician who thinks of sending a patient to Aix-la-Chapelle.

*Handbuch der Physiologische Optik.* Von H. VON HELMHOLTZ. 2te Aufgabe, 7te Lieferung. Hamburg and Leipsic: Voss. 1892.—The issue of the parts of this important work proceeds with unaccountable slowness. No doubt Helmholtz is a very busy man, and it cannot be denied that considerable additions have been made to the original treatise; but the first part of the second edition appeared in November, 1885. It was announced that the work would be completed in ten parts; the seventh part is now reached, and only about half the work is finished, whilst seven years have elapsed. If the same time is taken for the second half, a revision of the first 500 pages will be requisite. The present part deals with the phenomena produced by quickly recurring impressions, such as those obtained by spinning tops with coloured discs and the images obtained by Maybridge and Auschütz, which, the author rightly observes, present the movements of animals with extraordinary fidelity and supply important information in regard to the muscular movement of animals. The part also contains an account of after-images and of contrast and complimentary colours, and concludes with some observations upon induced colours.

*The Journal of Physiology.* Edited by MICHAEL FOSTER. Vol. XIII., No. 6. Cambridge Engraving Company. October, 1892.—This part contains the following memoirs: V. D. Harris and W. J. Gow, Ferment Actions of the Pancreas in Different Animals; R. T. Hewlett, Fractional Heat Coagulation; W. T. Porter, Researches on the Filling of the Heart, with two plates; J. N. Langley and H. K. Anderson, on the Mechanism of the Movements of the Iris; A. E. Garrod, on the Occurrence and Detection of Hæmatoporphyrin in the Urine, with a plate; C. S. Sherrington, Notes on the Arrangement of some Motor Fibres in the Lumbo-sacral Plexus, with four plates.

## New Inventions.

### SACKLINS' PATENT READY-MADE POULTICES.

THE linseed poultices are made with the best crushed linseed, containing the full quantity of oil, and the linseed is sewn securely between muslin and waterproof calico, the latter keeping in the heat and moisture. They also contain 2 per cent. of boric acid, which is dissolved at the time of using and renders them antiseptic. The septic qualities of the ordinary poultice are done away with, and these poultices can be applied to an unbroken surface with safety. The sewing is done in such a manner that the linseed is secured in many square-shaped compartments, and by cutting along the seams it is possible to make them of the required size. When wanted for use, it is only necessary to pour boiling water over the poultices and to apply them. It is said that they may be redipped in boiling water and applied thirty times consecutively without appreciable diminution of their remedial value. The least experienced nurse can hardly spoil them, and they are certainly of much greater cleanliness in use than the average poultice of domestic life; no pieces of linseed adhere to the skin on their removal, and as they are ready-made and can be at once applied, they should find a ready sale; they are, moreover, cheap. The mustard poultices are made of pure mustard flour and ground mustard husk which contains a large percentage of bland oil, and prevents the painful effect of the mustard. They are mild and are said not to blister the skin should the patient fall asleep and wear one all night; they can therefore be tolerated for a long time and the effect of the counter-irritant is made more lasting. They are manufactured by Messrs. Sacklins and Co., 20, Royal Exchange.

## INSTRUMENTS FOR BONE SUTURE.

ANNEXED is a woodcut of the bradawl and director used at the West London Hospital in suturing bones, either by subcutaneous or by open operation. They were made for me by Messrs. Maw, Son and Thompson in April, 1889. The bradawl is of one piece of steel, without any angles or mouldings to collect dirt, and is nickel-plated. These peculiarities are, of course, for ease of purification. It is also used for aseptic cases only. The director is a size less in diameter than the bradawl and ought to be of uniform calibre throughout. That it is not quite so in the specimen drawn is an accidental error. Like the bradawl it is of steel, nickel-plated. The blade of the bradawl is 3½ in. long and of a size intermediate between a No. 8 and No. 9 catheter (French scale). The director is of the size of a No. 7 (French) and the wire generally employed is equal in thickness to No. 3 (French). The length of the bradawl is a great convenience and is intended to make it available for the subcutaneous suture of superficial bones, like the patella and olecranon. About two years after these instruments had been constructed first a long drill-bit perforated at the end, and afterwards a long bradawl, also perforated at the end, were described and recommended for subcutaneous suture. The idea of a perforated bradawl was rejected at the time when the instruments I am describing were first planned, as tending to at once increase thickness and diminish strength ;

for a too thick awl will split a patella and a thin and perforated awl is liable to break. These are not mere theoretical objections ; I have seen the patella split in three cases and I have in my possession the broken stump of a perforated bradawl made two years and a half ago. With the long-bladed awl and director to match I have sutured various bones, including the femur, the tibia, the patella, the olecranon and the astragalus and scaphoid. The director should be passed as far as the bone along the awl before the latter is withdrawn ; and of course the wire, previously straightened, is slipped through in the groove of the director. When wiring subcutaneously the wire, after passing through the bone fragments and emerging at the second skin aperture, is returned through the same aperture along the director, previously thrust back between the skin and the bone, to the original skin opening. Also, when the awl has perforated one fragment it should be used carefully as a probe (in conjunction with digital palpation from without) to ascertain the bearings &c. of the other fragment. In this way can be avoided the error of attaching the anterior surface of one fragment to the fractured surface of the other in a patella case. The results which can be got by such operations as Mayo Robson's show that the inversion of periosteum between fragments of patella has not the practical importance once attached to it. Close union of any kind, either bony or fibrous, suffices in the case of a bone which is merely inserted in an aponeurosis and which does not form part of the main skeleton. The openings made for and by the awl and director give ready egress to all liquid effusions, but not of course to clots.

Grosvenor-street, W.

C. B. KETTLEY, F.R.C.S. Eng.

## THE HECLA FOOT AND BED WARMER.

MESSRS. W. SHIRLEY AND CO. of Lord-street, Wolverhampton, have submitted to our inspection a specimen of the above appliance. It consists of a cylindrical vessel about a foot in length, made of block tin, with a screw stopper, and enclosed in a woollen jacket. The convenience of form renders it applicable to the two purposes of bed-airing and foot-warming. It is cheap and handy, and is likely to prove a welcome adjunct to household comfort.

## THE COMMON ROOM FOR FELLOWS AND MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

IN pursuance of a resolution of the Council of the Royal College of Surgeons of England the room, adjoining the secretary's office, which formed part of the library not used by readers has been furnished as a common room for the use of Fellows and Members of the College. The room, which is spacious, and looks on to the garden of Lincoln's-inn-fields, has been handsomely and comfortably furnished with a Turkey carpet, two walnut octagonal tables, writing tables, settee, and a suite covered in morocco leather, together with a hat stand and umbrella stand. The principal daily and weekly newspapers are also provided. The regulations for the common room are the following :—

"1. The common room is open to Fellows and Members of the College only. 2. The common room is open on each weekday from 11 A.M. till 5 P.M. except Saturdays, when it is open from 11 A.M. to 1 P.M. It is closed during September and at such other times as the Council may direct. 3. No formal meeting of any description may be held in the common room. 4. Fellows and Members writing letters at the College may not use the College as their address.

"Note.—Fellows and Members are reminded that smoking is not permitted in any part of the College premises.

"Nov. 10th, 1892."

"EDWARD TRIMMER, Secretary.

The common room was opened on the day of the Bradshaw Lecture, Thursday, December 1st. A good fire is kept burning and the room wears a cheerful and comfortable aspect. Writing materials are provided. Probably very few of the Fellows and Members of the College are at present aware that a common room is in existence and it may be anticipated that it will be found useful by those who frequent the library and museum, or attend the lectures and meetings at the College. The room was obtained for the Fellows and Members through the application of the Association of Fellows to the Council of the College.

## THE DENTAL HOSPITAL OF LONDON.

THE annual dinner of the past and present students of this institution was held on Saturday last at the Café Royal. Sir Richard Quain, F.R.S., supported by Dr. Hare and Mr. Bryant, the President of the Royal College of Surgeons, occupied the chair. The health of the past and present students having been proposed and duly honoured, the chairman alluded to some of the more distinguished men who had passed through the hospital and school. Referring to the action of the General Medical Council, he said they are willing to take, and are taking, great interest in advancing this department of the healing art, and he could assure his hearers that that body would do all in their power to help the dentists ; but they must help themselves, and he could prophesy a great future for them if they would avoid unprofessional actions and devote themselves earnestly to their noble profession. Mr. Bryant recognised in the hospital a valuable institution for the treatment of the suffering poor, and in the school an excellent educational establishment which provided properly qualified and skilled dental surgeons for the rich. Dr. Hare, replying for the hospital, urged its claims upon public sympathy and monetary support to provide increased space and larger opportunities for work. Dealing mainly with statistics, the dean of the school, Mr. Morton Smale, said that the development which had taken place on the scientific side of dental surgery, and the fact that it was now a legalised profession, had produced two results—first, an immense increase in the number of cases treated (last year the numbers were 54,177) ; and, secondly, a large increase in the number of students. This tended to a crowded state of an already over-burdened institution, and the only remedy was to provide a new and more commodious hospital building. Such a change would necessitate an expenditure of £40,000, of which £3000 had already been promised by members of the staff and friends. He was confident that the public would soon provide the remainder. An excellent programme of music, which was partly contributed by the Hospital Glee Society, added to the enjoyment of the evening.

# THE LANCET.

LONDON: SATURDAY, DECEMBER 10, 1892.

THE hospital problem, or rather the problem of hospital support, still continues, in spite of the Lords' Committee, to be an anxious one. Something in the way of excuse for delay must be set down to the recess. It is not in human nature to study such problems during holidays, or when grouse and partridges have to be dealt with. Our readers may remember that a conference was held in May, at Spencer House, of some of the principal governors of the larger London hospitals, to consider whether anything could be done in regard to certain recommendations made by the Lords' Committee. A committee was appointed to take into consideration the whole of the recommendations and to report to the conference. That committee, we understand, has met once, and a subcommittee of four was then appointed to make a detailed examination of the Lords' proposals in the report.

The public will anxiously look for the suggestions of this subcommittee. It is obvious that if any practical result is to follow the laborious and painstaking investigation by the Lords' Committee time must not now be lost. The report of such a committee is never so strong as when it is fresh in the minds of the public, and when those who have framed it are full of the interest of the subject and the information they have gathered. The principal recommendation of the Lords' Committee is certainly that in favour of the creation of a Central Board. There is much difference of opinion as to the feasibility of such a Board, or rather as to the feasibility of all the powers suggested by the Lords' Committee. It proposes that this Board may receive endowments, legacies and donations, and have power to publish complete statements as to the pecuniary position of each medical charity &c.; but it does not invest it with the much-needed power of controlling the erection of new hospitals, which are likely to compete with existing institutions whose wards are empty for want of funds. No doubt the distribution of existing hospitals is very faulty, but this objection is considerably weakened by the improvement in the ambulance arrangements of the metropolis, which are as yet imperfectly enjoyed by the hospitals and the patients who enter them.

Apart from the debateable portion of the report it is full of suggestions which cannot be too soon tested by being subjected to minute examination by those who are really interested in the maintenance of our existing hospitals. Some central supervision is wanted, and so long as it is helpful and friendly, not too imperious, and does not tend to compete with individual hospitals or withdraw credit and endowments from them, it is likely to be acceptable to the governors of the different institutions. The Hospital Sunday Fund and the Hospital Saturday Fund have always been very respectfully treated by the committees and governors of the various institutions, largely because these funds have given a great amount of help with the smallest amount of

interference and of criticism. If the subcommittee now engaged in detailed examination of the Lords' proposals can suggest a Central Board that will be as little officious and as helpful as the councils of these funds it will do much to give effect to the Lords' main proposal, and also to all the other principal recommendations.

The voluntary support of the hospitals and dispensaries is, and must continue to be, their glory and their strength. Nothing in the functions of the Central Board must be allowed to offend the sense of independence or the *amour propre* of the individual institutions. Public opinion is still in favour of our voluntary system, and the Lords' Committee recognises this, and rejoices in the fact. Its report is friendly, and, with the exception of an inadequate note on the out-patient abuse, is satisfactory, and even complimentary to the system. It recognises that the function of the hospitals is essentially a charitable one; and that so long as they keep to this character and guard against abuse they are worthy of all the support of the rich and well-to-do classes, who benefit indirectly by them as educational institutions and training schools of the highest medical and surgical skill. This is the overwhelming estimate of hospitals in this country. A gentleman the other day tried to induce the Birmingham and Edgbaston Debating Society to declare that, as the hospitals of the city exist for the benefit of the whole of the community, and especially for the benefit of the medical profession, and are now so largely supported by the artisan class, they should be regarded as coöperative institutions rather than charities. The proposal was rejected by a large majority, as it deserved to be. Hospitals are for exceptional cases, not for common complaints. Without making any invidious comparisons of the way in which they have been supported by different classes, they have been a noble feature in the charities of this country; and the exhaustive examination of them by the Lords' Committee emphasises this conclusion. To convert them into mere coöperative stores for the relief of all comers, and of comers that should be attended at home by the family or the club medical man, would alienate their principal supporters. Birmingham did well to reject such a trade view of its great hospitals.

IN his recent work on "The Climate of Rome and the Roman Campagna," Professor TOMMASI-CRUDELI devotes a valuable chapter to the subject of the preservation of human life in malarious countries. Our readers will be glad to have in a compact form the views of so eminent an authority on this very important and interesting topic. We must be content to admit that for the present we have no precise knowledge of the nature of the malarious poison or of the means whereby it can be extirpated from the soil of an infected locality. That the poison inheres in the soil; that it is greatly under the influence of season, temperature and rainfall; that it is excited to fresh activity by all measures involving the disturbance of earth long left quiescent; that its ravages have been much reduced by drainage, by the conversion of naked soil into meadow land, and by the erection of houses and laying down of paved streets—these facts are certain, and almost exhaust our knowledge on the subject.

Professor TOMMASI-CRUDELI points out that the traditional precautionary measures long adopted in malarious countries have had two ends in view—viz., to reduce as much as possible the quantity of the malaria ferment which enters into the system through the air breathed and to prevent a lengthened abode of the same in the system. The first point is sought to be achieved by avoiding agricultural operations during those hours at which the malarious influence is most potent—viz., about sunrise and sunset; hence, according to the writer, is really explained the much misunderstood dictum of the ancient Sybarites: "If you wish to live long and well do not ever see the rising or the setting sun." Another point of the greatest importance is to avoid breathing the air in close contact with the soil, as it can be shown that the malarious poison rises only a short distance in a vertical direction. Thus in the Pontine Marshes, an intensely malarious region, platforms four or five metres high are erected, upon which the people sleep in the open air with comparative impunity. In Greece, the jungles of the East Indies, and Central and Southern America, similar devices have been adopted with beneficial results. Another mode of eluding the malaria-laden air in close contact with the ground is to construct the dwellings in such a way that when the door is shut the internal atmosphere is renewed only by the strata of the local atmosphere which are near the roofs of the houses. This is managed in some localities by so arranging that the only opening in the outer walls is the door, and all the windows open on an inner yard at a higher level than the ground floor of the house. It is advisable also to keep the windows of the houses closed in the morning and during the early hours of the evening, especially if any excavations should be going on in the neighbourhood. Care should be exercised regarding the effects of placing vases of flowers in occupied rooms; either these should be entirely excluded from houses when malaria is rife or the utmost vigilance should be taken to secure thorough ventilation.

The above measures all aim at preventing the reception of the malarious poison into the system or of reducing the amount received. Other measures are directed to preventing the germs, already absorbed, from remaining in the human body for any length of time. These measures, according to Professor TOMMASI-CRUDELI, all resolve themselves into expedients for maintaining in an active and regular condition the circulation of the blood. Everything that tends to keep the secretions healthy and active promotes the elimination of the malarious poison and reduces the probability of it effecting destructive changes in the body. The principal indications are to maintain constitutional vigour by good nourishment, the moderate use of wines and spirits, and to avoid all disturbance of the system from variations of temperature. Hence warm clothing, even in the hot season is indispensable.

The difficulties regarding the above preventive measures are the time, expense, self-restraint and inconvenience involved in carrying them out. Acclimatisation comes to our aid; not, however, acclimatisation of the individual, but of the race. "This power of constitutional resistance has been proved to be hereditary, and the repeated selections, caused by malaria in each generation, have conduced to the eventual increase of the resisting powers of the race, and that to such a degree as

to enable it to found powerful colonies in unhealthy sites, such as in Italy were those of Selinunte, Agrigentum, Sibaris, Paestum and Rome."

The chief remedies that have been used to combat malaria are quinine, arsenic, eucalyptus, salicylates, the fruit of the lemon &c. The good effects of quinine are, of course, unquestionable. Its anti-malarious influence is, according to Professor TOMMASI-CRUDELI, rapid but fugitive. Quinine is, unfortunately, rather expensive and tends after a time to disturb the digestive organs and the nervous system. Arsenic the writer regards as a remedy of the very highest value, especially as a prophylactic. He has instituted extensive experiments among the properties of the land-owners of Tuscany, Rome, Puglia and Sicily, and among the workers on the Roman and southern railways with encouraging results. Dr. RICCII, the chief medical officer of the southern railways, experimented in the year 1883 upon seventy-eight persons in the district of Bovino, where malaria is very virulent. He divided them into two categories, one of which only was subjected to the preventive system by means of arsenic. The result was that the great majority of those who took no arsenic (we are not told the precise number) had violent attacks of fever, while of those subjected to the arsenical treatment thirty-six escaped entirely, whilst the remaining three had only slight attacks. Other experiments were not less satisfactory, and some cases of failure were attributed to the arsenic having been administered in a non-assimilable form. Professor TOMMASI-CRUDELI has no faith at all in the alleged anti-malarious influence of the salicylates, and attaches hardly any greater value to the use of eucalyptus. He also disputes the alleged beneficial results said to have attended the planting of eucalyptus trees in malarious regions. He thinks much more highly of a popular remedy widely employed in many parts of Italy, Greece, Arabia, the West Indies &c.—viz., preparations of the lemon tree. The most active preparation is said to be a decoction of the whole lemon fruit, and remarkable results are claimed for this cheap and simple remedy.

The net result of Professor TOMMASI-CRUDELI'S experience would seem to be that hygienic and dietetic measures are of the greatest importance in dealing with malaria, that arsenic has a true prophylactic influence, and that quinine and a decoction of lemons are the most valuable remedies during the actual attack.

HYDATID disease is sufficiently common in this country to make its treatment a matter of widespread interest in the profession; but the interest we feel in it here is as nothing compared with that felt by those who practise surgery in the Antipodes. There the question is often discussed in medical journals and at meetings, and it was most fitting that, at the Intercolonial Congress held at Sydney in September last, a special debate should have been arranged to elicit the opinions of those most experienced in the treatment of hydatid disease. The discussion showed that to a large extent there was no difference of opinion, although on one point the divergence of view was marked enough. All the speakers were agreed that in suppurating hydatids, and in hydatids with daughter cysts, aspiration of the tumour is ineffectual, and that the only proper treatment when the cyst is accessible is a free aseptic incision into the cyst with complete evacuation of its

contents. In hydatid disease of the lung aspiration has proved to be a very dangerous operation on account of the facility it affords of flooding the lungs with the cystic fluid. This point has been well illustrated by cases published in this country, notably by Dr. BRISTOWE and Dr. MACKENZIE, which are to be found in Vols. XXIV. and XXV. of the Clinical Society's Transactions. For such cases a careful incision into the pleura, followed by the free and complete evacuation of the cyst, is the best course.

The vexed question is, What is the best course to follow in cases of simple hydatid cyst of the liver or peritoneum? Dr. SYDNEY JONES and Dr. SCOTT SKIRVING advocated the treatment by aspiration, care being taken to employ a small needle, not larger than one-sixteenth of an inch in diameter, with full antiseptic precautions. They urged this on the ground of its simplicity and its safety, and also because, if followed by refilling of the cyst or suppuration, incision of the cyst can be practised without any additional risk or difficulty. They argued that inflammation of the sac is due to pyogenic organisms introduced by the needle, and that leakage from the puncture only occurs when a needle of large size is used. Dr. JONES points out that very soon after being emptied by an aspirator the tumour may be as large and tense as before aspiration, even in a few hours, from inflammatory exudation. He cautions his professional friends against mistaking this for refilling of the cyst with its proper fluid. The diagnosis is made by watching the cases. Where the cyst has become filled with serum, it begins to shrink in a few days and eventually all is absorbed. Where the fluid is cystic no such improvement takes place and treatment by incision has to be employed. Dr. JONES believes that many instances of so-called refilling of the cyst with hydatid fluid are cases of multiple cyst in which a second cyst has enlarged and occupied the space formerly taken up by the first. This is a matter hardly capable of proof.

The other view seems to have been the one held by a large majority of those present at the Congress. They advocated the entire abandonment of the aspirator and the employment of aseptic incision and evacuation of the cyst in every case which is accessible to the surgeon. In support of this view they refer to its safety when proper antiseptic precautions are observed and to its certainty of result. They oppose the use of the aspirator chiefly on the ground of the danger of its setting up suppuration or of leakage from the puncture into the peritoneal sac. They also urge that at the best it leaves the patient with a dead, collapsed hydatid cyst, and that it must be better to get rid of such a mass from the body than to have it lodging there indefinitely. Each party in the discussion quoted statistics and spoke with the fullest confidence in its own special views. It seems clear that surgical opinion has very largely veered round from faith in aspiration to distrust of it, and from fear of the radical treatment of the cysts to the fullest confidence in it. Time and experience will enable more evidence to be collected and sounder opinions to be formed. It is in harmony with the whole tendency of modern surgery to prefer the more radical measure and to abandon aspiration. We can hardly think that the hands of the clock will be put back and that surgeons will recur to an operation which is at best uncertain and sometimes mischievous. Dr. SYDNEY JONES and Dr. SCOTT SKIRVING have done good work in calling attention

very prominently to the conditions under which aspiration becomes a safe operation, for it is clear that up to the present it has been attended with a considerable mortality. But, unless we are mistaken, we shall before long see it abandoned entirely and aseptic incision and drainage regarded as the one trustworthy mode of dealing with hydatids of all kinds and in all situations which are accessible to the surgeon.

IN a recent number of the *American Journal of the Medical Sciences* Dr. ALLEN STARR of New York has written a paper of very great importance and of more than ordinary interest, in which he has brought together various cases observed by himself and others, from a study of which he is able to lay down some very definite rules as regards the symptoms of lesions situated low down in the spinal cord. The facts are drawn from the records of OPPENHEIM, ROSENTHAL, WESTPHAL, HUBER, BERNHARDT, OSLER, MILLS and EULENBERG, as well as from the observations which Dr. STARR himself has made in association with HERTER, LLOYD and MCBURNEY. In many of the cases the clinical facts are compared with the conditions found post-mortem, and as a result of comparison of the various conditions it has been possible to lay down a certain number of deductions of the greatest interest and of much practical importance. Thus it is found that the control of the sphincters of the bladder and rectum is lost when the lesion involves the lower three sacral segments, and the opinion is expressed that these centres probably lie in the two lowest segments of the cord. When these are destroyed the sphincter of the rectum is relaxed, and the entire rectum loses the power of emptying itself, so that artificial evacuation by means of enemata or excavation is necessary. As regards the bladder, on the other hand, the sphincter does not appear to be permanently relaxed when the cord is destroyed, so that constant dribbling rarely, if ever, occurs; but as soon as a few ounces of urine collect, the pressure is sufficient to overcome the slight resistance of the sphincter, and the urine flows away. Sufficient resistance in the sphincter to cause retention of urine is rare when the bladder centre is destroyed. Such a condition is more apt to occur when the lesion is situated higher, this effect then being due to irritation of the bladder mechanism. The same effect seems to be produced by lesions of the cauda equina, the result then being apparently due to a reflex irritation from sensory fibres. From this it is concluded that if, in a case of paraplegia, the mechanism of the bladder and rectum is not interfered with, so that these viscera empty themselves when full, the lesion has not destroyed the lower sacral segments of the cord. The other important deduction is as to the distribution of anaesthesia in lesions of the lower part of the cord. This is shown by means of ingenious diagrams constructed from a careful comparison of the conditions found in the different cases. The first zone is oval in shape and small in extent, including the perineum, the posterior part of the scrotum in males, and the vagina in females. It also included the mucous membrane of the rectum. The second zone is heart-shaped, with the point up, and includes the entire scrotum and posterior surface of the penis and mucous membrane of the urethra in males, and in females the entire genitals except the outer surface of the

labia majora and the mons veneris. These two zones can be separated clinically, but all that can be affirmed from post-mortem evidence is that the second zone is produced by a lesion involving the conus medullaris and the fifth and fourth sacral segments of the cord.

The third zone has been named the "saddle-shaped area," as it roughly corresponds with the surface of the body in contact with the saddle when riding. Such an area is shown by a necropsy to be the result of a lesion involving the fifth, fourth and third sacral segments. The fourth zone is larger but similar in shape to the third. The anæsthesia extends in the form of a strip almost as low as the popliteal space. Clinically this area has been evident in several cases, but so far there is no direct post-mortem evidence of its origin. But as it lies between two zones, one of which is the result of lesion of the third sacral segment and the other of the fifth lumbar, it seems evident that it is the result of a lesion of the second and first sacral segments. The fifth area is more extensive still, descending the back of the thigh through the popliteal space in a band and thence to the outer surface of the leg and foot. In some cases it stops at the ankle, in others it involves the entire side of the foot, dorsum and sole, and three and a half toes. This area corresponds to the fifth lumbar segment. The sixth area of anæsthesia is a result of lesion of the third lumbar segment. It involves the entire back of the thigh and leg and also the front of the thigh, except a funnel-shaped area with its broad end upwards. The narrow end of the funnel extends along the shin, even on to the foot, and the opinion is expressed that this zone will probably be differentiated into two, one corresponding to the third lumbar segment, the other to the fourth. The largest area of anæsthesia is produced by a lesion of the four lower lumbar segments. It follows the line of Poupart's ligament, and is much lower in front than behind. The abdominal walls are only affected if the first lumbar segment is diseased.

Such are the conclusions which Dr. STARR draws from his observations of the very interesting series of cases which he has been at pains to bring together. Their importance in regard to exact localisation is very great, and we have no doubt that further observations in the near future will enable the small gaps in the scheme to be filled up, and so complete a piece of work which is a model of careful and painstaking observation and deduction.

In the *Medical Chronicle* for September Dr. J. G. ADAMI (now Professor of Pathology in the University of Montreal) contributes a most interesting article on the Variability of Bacteria and the Development of Races. He has collected a very large number of records of variations in the manner of growth and modifications of the specific characteristics of some of the better known bacteria, and although it is impossible to agree with some of the conclusions arrived at as the result, no doubt, of a careful consideration and generalisation on these observations, the facts themselves, as marshalled in this paper, cannot but prove to be of great interest and value. First he deals with transient variability under the headings of change of form, changes in pigment production, variations

of ferment production and modifications of pathogeneity; he records the many changes that have been observed by various workers in organisms obtained from different sources and cultivated on various media; and he indicates how, although some of these changes may be transient and the original forms may be reproduced by transferring the organisms to suitable media, other alterations may remain more or less permanent. One very striking feature on which stress is not laid and has never been laid in this matter is that, although it has long been well known that the typhoid bacillus when separated by means of the carbolic acid method undergoes distinct morphological changes, this has never properly been associated with the marked diminution in virulence of the organism—a character which, once lost, it is very difficult to restore, the morphological characters being resumed under appropriate conditions much more readily than the specific pathogenic properties, and much of the haziness that exists on the question of the alteration of the virulence of the typhoid bacillus must undoubtedly be attributed to our imperfect methods of separating it and cultivating it outside the body. The colour variations, especially those of more permanent character, are described pretty fully, GESSARD's observations being made the basis on which the remarks are founded. The other interesting question of the identity or specificity of the streptococcus erysipelatis and streptococcus pyogenes is taken up in the discussion on natural races. Dr. ADAMI appears to agree with CROOKSHANK, BEHRING and FRAENKEL that these two organisms are identical, and that the differences as regards manifestation when introduced into the animal body are due entirely to the different tissues or positions into which they are inoculated. There can be little doubt that recent experiments confirm this idea, although we have still to get over the fact that the chemical products of these organisms differ somewhat seriously when they are cultivated outside the body. It may be, of course, that they are modified according to the position of their growth in the body, but it still would appear that the chemical products of the organism play an important part in determining the pathological manifestation indicative of their presence in the body. It is not necessary to follow Dr. ADAMI in his remarks on the observed modifications of pathogenic microbes, the examples which he gives being those of pneumonia, typhoid fever, cholera, tuberculosis and diphtheria. We have so little standard as to what should constitute a race, what a type, and what a variety that no two observers will place exactly the same value on Dr. ADAMI's generalisations; and we cannot but think that in some instances he has assigned far too great importance to trifling variations, whilst in other instances more important factors have been left out of account. Unfortunately we have as yet no standard either of nomenclature or of classification. It may be objected that, with the limited knowledge we have of micro-organisms, exact or final definition is not possible, and that all our observations can only be of tentative value. Dr. ADAMI's contribution, however, will prove useful, especially to those who wish to obtain a rapid and comprehensive view of the subject. His list of references is exceedingly full and will help workers to economise considerably, both as regards time and trouble.

## Annotations.

"Ne quid nimis."

### A PROFESSORIAL UNIVERSITY FOR LONDON.

WHEN Professor Karl Pearson first launched his scheme for founding in London a University in which the professors were to have a predominant power, and into which existing institutions of academic rank in London were to be absorbed, we pointed out that such an ideal University could not possibly be founded in London, inasmuch as the present University, the teaching colleges and the medical schools would take no part in its formation, but would use every endeavour in opposition thereto for the protection of their own interests and trust funds. We also clearly showed that a "federated" University was much more feasible, and our preference for the Gresham Charter arose from its being based on the principle of such a federation. We were much surprised when in June last we received a long list of eminent names supporting Professor Pearson's scheme for promoting a professorial University. But we now find that this is all a mistake. Whilst Professor Pearson meant one thing by a professorial University Professor Huxley and the rest of the Executive Committee of the Association (of whom three are Fellows of the Senate and another is the Assistant Registrar of the existing University of London) meant something quite different. From a recent correspondence in *The Times* we learn that Professor Pearson has resigned the secretaryship of the committee because that body is conferring in some way with a committee of the Senate of the University of London, which is apparently engaged in drawing up another "further revised" scheme to be placed before the Royal Commission. By supporting a new scheme of the Senate which Professor Pearson evidently thinks will be the outcome of such a conference, the Executive Committee will practically throw all the weight of the Association into the scale in favour of a modification of the existing University rather than endeavour to form a new institution which should absorb all those already at work on higher education in London, which latter plan is, we believe, Professor Pearson's ideal. Hence he separates himself from his former colleagues on the committee, for in his opinion they are not keeping clearly enough in view the professorial as distinguished from the federal University, which is the essential aim of the Association. It will be interesting to notice whether the eminent men who belong to the Association will adhere to the views of its founder or will follow the more practical method on which the committee now seems to be engaged. Professor Huxley's evidence before the Gresham Commission, as given in his draft statement, is entirely in favour of a federated University under the title, and prestige of the present University, which is to be reorganised so as to take in the technical schools of theology, law, medicine, engineering &c., as colleges of the University, and is to give those schools power to examine their own students for degrees, under conditions determined jointly by them and the Senate of the University, and this evidence had the "general approval" of the Executive Committee, who apparently paid but little attention to Professor Pearson's protests. We certainly did not understand that these were the views of those who originated the Association for promoting a Professorial University, and we cannot easily read them into the proposals adopted by the Association in June last. Professor Huxley, however, says that it is quite a mistake to suppose, as applied to the University, that "professorial" and "federated" are really opposed, and that what is required for London is a voluntary association for purposes of general government, with the

reservation of special interests so as to secure a "federation" of a kind sufficiently close to ensure unification for University purposes. It is evidently very annoying to Professor Huxley to find this federation scheme thrown over by Professor Pearson; but it must be remembered that Professor Pearson started the Association and denominated it one for promoting a *Professorial* University for London, and he did not, we gather, intend that any compromise with existing interests should block the way towards the attainment of his ideal.

### MR. GLADSTONE AND LIVERPOOL.

IT is always a source of pleasure to us when Mr. Gladstone leaves the party sphere of discussion and allows himself to take an excursion into other fields of reflection, as he did on Saturday last, when Liverpool enrolled him on the list of her freemen. The changes which have come to pass in his native town within his own memory form a congenial theme for any orator. It is not the least illustration of Mr. Gladstone's greatness that he can expatiate on all these changes—on the replacement of sandy beaches and wild flowers by dingy additions to the town and the replacement of a comparatively clear atmosphere by a pall of smoke—and yet conclude by finding material of hope and of ever-brightening prospects for a community whose social and sanitary affairs have often been the concern of moralists and sanitarians. Most men over eighty visiting the scenes of their boyhood where their ancestors had played a distinguished part would be apt to feel some moody sentiments and to moralise on the changes and chances of this mortal life; but there was no such note in Mr. Gladstone's speech, and, liberal and prosperous as Liverpool in the past had been, he anticipated, in spite of all changes, that she would be greater in the future than either her present self or any of her rivals. There was, indeed, one word of shame and grief over the drunkenness of the land, nowhere, perhaps, more to be lamented than at Liverpool, and we must believe that the use of such words by Mr. Gladstone in his present position was neither casual nor insignificant. It is gratifying to know that much high and satisfactory work is being done in Liverpool both by municipal authorities and by personal and religious effort to improve the people of that great city, which represents our contact with the new civilisation of the West. From a sanitary point of view it is clear that such work is being rewarded. We have only to look at the last report of the medical officer of health for the City and Port to see that an impression has been made and is yearly more and more being made on the diseases which have long testified so graphically to the degraded and cramped condition in which the majority of the people have lived in the second greatest city of the kingdom. It would be poor satisfaction, according to Mr. Gladstone's estimate, for Liverpool to go on adding dock to dock and street to street unless she can show corresponding improvement in the state of her poor. The first conditions of such improvement now exist. Her medical officer can lay his hand on every street, and on every house in every street, that supplies the diseases that imply poverty and misery so deep that they can only be reached by special measures of help and rescue. Liverpool still shares the unenviable distinction of being the most densely populated community in the United Kingdom. She still squeezes 99·3 people into an acre, while Glasgow only compresses 92·8 and London 56·5, and she still has 5·67 persons in a house, as compared with 6·1 persons sixty years ago. She is, however, demolishing houses unfit for human habitation at the rate of nearly 500 a year. The deaths from zymotic disease for last year were the lowest recorded. The deaths from fever last year, in its large sense of continued fever, were 131; whereas the average of the preceding ten years was 270. There is—and this is one of the most hopeful facts—a steady decrease of deaths below the

age of five years. Corresponding with this is the large decrease in deaths from diarrhoea—mostly an infantile disease. There is a great fall in the deaths from tuberculous disease. Every house from which fever cases or diarrhoea cases proceed unduly is marked and known to the medical officer and his staff. These are the first drops of a shower of benefactions that will fall on not only the poor of a great city, but on its municipal and its social leaders, when they come to perform the duty which Mr. Gladstone so eloquently enforced—namely, that of attending not only to the promotion of the increase of material wealth, but of all that elevates human nature and human life.

#### PREVENTION OF LEAD POISONING AMONGST GLASS POLISHERS.

LEAD POISONING amongst glass polishers due to the tin putty employed may, according to M. Guéroult, be entirely abolished by a new plan which has for the last eighteen months been adopted at the Baccarat Glass Works. The old tin putty that was used was a stannate of lead which was manufactured in special furnaces by oxidising three parts of lead with one part of tin. In the new material two parts of metastannic acid are added for each part of putty, the lead being reduced to about a third of the old proportion. Under the former system numbers of workmen suffered from lead paralysis, and many had to leave the works entirely. Since the introduction of the metastannic acid putty, however, not a single case of lead poisoning has occurred.

#### THE THIRSK RAILWAY ACCIDENT.

THE trial for manslaughter of James Holmes, the signalman whose forgetfulness produced the lamentable railway accident at Thirsk, has resulted in a verdict of guilty, the only verdict possible in the circumstances of the case; but the Court, taking a merciful view of the offence, has released its prisoner upon his binding himself to come up for judgment if called upon, thus in effect waiving punishment altogether. This result is one with which the public may, we think, be very well content, so far as it goes. That Holmes was in fault there can be no doubt; it is equally clear that his fault was a very grave one. But even grave faults do not of necessity call for punishment, and the present is eminently a case in which the exercise of clemency is to be approved. The case has, by reason of the magnitude of the calamity involved, been made the subject of much discussion, and the infliction of exemplary punishment could not heighten the effect which has already been produced. On the other hand, it is abundantly clear that the unhappy man himself, on whom the chief responsibility for this disaster rests, is only in a very limited sense chargeable with what has happened. He was at the time of the accident suffering from the effects of grief, anxiety and broken rest, and certainly not in a condition to do himself justice in the discharge of his work. It is easy after the event to perceive that he would have been wise to press his demand for exemption from duty on this particular night, a demand which it now appears would have been conceded had it been urged. But he did not appreciate how much below par he had fallen, and it can hardly be reckoned a shortcoming that he should be slow to acknowledge even to himself that he was unfit for work. When to these extenuating circumstances is added the fact that his behaviour since the calamity has been open to no reproach it will, we think, appear that this is one of those rare cases in which a crime has been committed by a man in no sense criminal. The exoneration of the signalman from so much blame involves, however, a careful consideration of the system under which the work of the signal-box is carried on. We do not now refer to the perennial subject of protracted hours of labour. The present does not seem to be a case of that sort, for although Holmes

appears to have suffered, as we have already said, from broken rest, his vigils were occasioned, not by official duty, but by domestic complications. Against such a contingency no conceivable system of distribution of work can possibly provide. But what does strike us is that no passenger traffic ought nowadays to be carried on save upon an efficient system of interlocking points. If the levers in this cabin had been so connected together that it would be impossible to move them in mistaken order, the signalman's lapse of memory would have been at once corrected when he came to manipulate the points, and no more serious consequences could have ensued than a little delay of the traffic. The Board of Trade has, by persistent work during the past ten years, done much to improve the rolling stock, and especially the brake equipment, on our various railways. We hope that it will now turn its attention seriously to this no less important point of the proper organisation of systems of interlocking the signal levers.

#### THE MEDICAL AID ASSOCIATION QUESTION AND THE PRESS.

JUDGING from the many notices of this subject in the press, it seems to be recognised as one of importance not only to the public, but to the profession. On the whole, the notices are in a tone of which the profession has no reason to complain. The *Weekly Budget* says: "Of all classes of unionists the doctors are least liable to have to encounter a lock-out." "The doctors" have never had reason to complain of being locked out, but of having been the least paid and the most tardily paid profession—a body of men who are supposed to be at the beck and call of everybody night and day for *nothing*, or for the meanest sums. The profession is the last one that is likely "to strike"; but that is only a strong reason why its relations to the public should be well considered.

#### THE PREVALENCE OF SMALL-POX.

THE small-pox epidemic at Warrington is, we trust, on the highway towards abatement. In the week ending Nov. 12th no less than seventy-six fresh attacks were notified, in the two next weeks the numbers were thirty-two and twenty-four respectively, and in the week ending the 3rd inst. the new cases were thirty in number. During the last three weeks an immense amount of revaccination has been carried out, some 8000 persons having submitted to the operation; and concurrently with this the number of fresh attacks has diminished until now it is hoped that there will be no need to provide a third small-pox hospital. Amongst measures of prevention which have been urged on the local authorities has been the closure of the elementary schools. Mr. Gornall, the health officer, however, at once set his face against this. Not only would school closure, in his opinion, have led the children to mingle more freely than ever with persons living in and coming from infected houses, but he was able to point out that whereas in pre-vaccination days there was a special excess of small-pox in young children, these have shown themselves in this epidemic to be a class which has been remarkably exempt from the disease. In short, young children still retain the protective influence of a comparatively recent vaccination, and with it they exhibit a corresponding immunity from small-pox. The Royal Commission on Vaccination have, as we noted last week, appointed Dr. Savill to inquire into the circumstances of this epidemic, and we shall therefore later on possess an authoritative account of the progress of the outbreak and be enabled to judge how far its apparent increase owing to aggregation of the sick in hospital and the apparent connexion of its abatement with a period of increased vaccination are borne out by the actual facts. Thus far it is estimated that the cost of the epidemic to the town has been not less than £5000, and at

the same time trade has been most seriously hindered. From St. Helens we hear of ten cases of small-pox; the disease has again broken out in the Dewsbury district, both Dewsbury borough and the towns of Heckmondwike, Batley and Soothill Nether being attacked. Amongst other localities where the disease has appeared or is still maintained are Brighouse, Lightcliffe, Stockport, Rotherham, Wakefield, Lancaster, Manchester, Oldham, Chadderton, Birkenhead, Ashton-under-Lyne, Keighley, Halifax, Bradford, Derby (where four attacks occurred last week), Brierfield, Hipperholme, Thrintoft and Brompton near Northallerton, Enderby near Leicester (where a navy from a lodging-house has been placed in a tent), Dronfield, Kinsley in the Hemsworth rural district, Liverpool and Manchester. In Manchester only two fresh attacks occurred last week; in Leicester there was one case; in Liverpool the new cases were eight and five respectively in the last two weeks. At Lightcliffe the disease, according to a resolution of indignant ratepayers, "rages in the district," and efforts are being made to arrange for the isolation of the sick in the Brighouse district, although the Lightcliffe people refused to join Brighouse in making hospital provision. In connexion with the prevalence in Islington it is stated that small-pox has broken out in Pentonville prison. Two fatal attacks occurred in London last week. The disease has also appeared north of the border. In Glasgow between thirty and forty small-pox patients are under treatment in the Belvidere Hospital; from Edinburgh only a single case is as yet recorded. The wide diffusion of the disease to which we have for some weeks past drawn attention cannot fail to be a source of considerable anxiety at this very ominous season of the year, and it remains to be seen how far our improved means for promptly hearing of first attacks, taken together with the increasing efforts on the part of the inhabitants to secure the earliest possible isolation of the patients suffering from the disease, will go towards counteracting the mischief that has been wrought by people who, vaccinated themselves, endeavour to persuade other persons not to secure for themselves or their children the same measure of protection.

#### HEREDITARY ATAXY.

In the last number of *Brain* Dr. Sanger Brown of Chicago has described a series of cases of extreme interest. The series comprises in all twenty-one cases spread over four generations. Of these twenty-one six have been under Dr. Sanger Brown's observation for several months and two have been examined and reported on by Dr. Norman Bridge. In summarising the results of his examination and investigation Dr. Brown found that, as we have said, the disease was traceable through several generations. He also found that it increased in extent and intensity in the later generations, tending in them to occur earlier in life and to advance more rapidly. It occurred most frequently between the ages of sixteen and thirty-five, but it began in one case as early as eleven and in another as late as forty-five. No obvious preference for sex was manifested, but it descended through females more frequently than through males. No marked influence of any exciting cause could be demonstrated, although in some cases a fall or an injury preceded the onset of symptoms. Any depressing condition also, such as lactation or pregnancy, seemed to produce a rapid advance in the symptoms. There was considerable incoördination of the voluntary muscles when the disease was well established. This was evident first in the legs, but later might extend to the arms, face, eyes, head and articulatory apparatus. Sometimes this tendency was first manifested in the arms, sometimes in the articulatory apparatus. The ataxy was often extreme before the power of walking was lost, but it was not increased by closing the eyes, and the

sense of posture was perfect. Although there might be weakness of the legs in the advanced condition there was no muscular atrophy, and in some patients there was permanent spastic contraction. In well-marked cases there were extensive choreiform movements, occurring in the hands, legs or head whenever an attempt was made to maintain the parts in a fixed position. These movements ceased during sleep. There was usually some ptosis and at times transient diplopia in the early stages, the result of weakness of the external rectus. There was no nystagmus, but optic atrophy was an early and constant symptom. The response of the pupil to light and during accommodation was sluggish. It was present, however, so long as the atrophy was not complete. The articulation was markedly disturbed, and in some instances there was a tendency for liquids to enter the larynx. In some cases only—in those in which spontaneous pains in the legs coexisted—the sphincters were slightly affected. The knee-jerk was invariably exaggerated; ankle clonus was frequent. The cutaneous reflexes were also exaggerated (this was especially the case in the early stages); they frequently declined considerably when the disease was far advanced. There was no talipes or other deformity, excepting rarely permanent spastic contractions of the legs in advanced cases. Such is the summary which Dr. Brown gives of his cases, and it will be evident that they form an extremely interesting group. They differ in many material points from ordinary cases of the hereditary ataxy described by Friedreich, notably in the condition of the reflexes; but whether the symptoms in those cases are to be ascribed to a similar underlying pathological condition it is impossible to say. In a critical note on the paper Dr. Ormerod directs attention to the cases recently described by Nonne (which closely resemble Dr. Brown's), in one of which a necropsy revealed no degeneration of tracts in the spinal cord, but a marked diminution in the size of the cerebrum, cerebellum, pons, medulla and cord, and an excess in the numbers of the fine nerve fibres in the spinal nerve roots. A case under Menzel closely resembling these is also referred to, in which at the necropsy this diminutive condition of the nerve centres was found to coexist with degeneration in the posterior columns and pyramidal tracts of the cord; and it is noteworthy that the same condition has been found post mortem in Friedreich's ataxy. Professor Bernhardt also criticises Dr. Sanger Brown's cases, and agrees with Dr. Ormerod, and indeed with Dr. Sanger Brown himself, in believing that in a strictly systematic sense the cases do not belong to Friedreich's type, although they would certainly be placed in a category of hereditary or generic ataxy. To every neurologist the cases are of the utmost interest, and Dr. Sanger Brown is to be congratulated on his good fortune in meeting with them as well as upon the care and thoroughness with which he has investigated their condition.

#### SEPARATED MILK.

THE grievance brought to the notice of the President of the Board of Agriculture and to the Parliamentary Secretary of the Local Government Board by a deputation from the Central Association of Dairy Farmers last week is an obvious one. It appears that a large quantity of "separated" milk comes to London for the purpose of being mixed with new milk, the mixture being sold as genuine at a lower price than actually genuine milk could be supplied for. Honest dairy-men therefore laboured under considerable disadvantage, and they asked the Board of Agriculture to help them by law or by regulation, so that such a mixture should be sold for what it really was. The reasonableness of this request must be admitted, and was admitted by Mr. Herbert Gardner and Sir Walter Foster; but the difficulties in the way of legislation upon this matter are not inconsiderable. Until a definite standard with regard to the quality of milk is decided upon it is not clear as to how this state of things is to be remedied. There are

poor milks and there are rich milks, the former being as genuine as the latter. Public analysts are therefore compelled to adopt a low standard or else run the risk of very occasionally prosecuting—in the event of the milk being genuine, although of wretched quality—an honest dealer. On the other hand, it is equally clear that rich milk may be diluted down to the poor standard and yet be regarded as genuine. This applies to the fat of milk as well as to the non-fatty matters. In view of the fact that the low limit adopted by some analysts is only approached in some few cases, as shown by the figures of an enormous number of analyses, it seems to us not unreasonable to suggest that the Act should only countenance the sale of milk of good average quality. It is well known that poor milk is in most instances yielded by ill-fed and ill-conditioned cows—and this is a point which should be considered. If, at any rate a cow does yield milk of poor quality under normal conditions, such milk should be mixed with the rich and healthy product of other cows.

#### THE DENTAL HOSPITAL OF LONDON.

THE annual dinner of this institution was held last week under the presidency of Sir Richard Quain. The large number of distinguished guests present and the keen interest shown by all in the welfare of the hospital and school, must have brought to the minds of many, perhaps more especially old students, the days not far distant when their quarters were in a small private house in the south-west corner of Soho-square, with but five or six chairs in the badly lighted stopping-room. The first move was to a large, specially constructed building in Leicester-square, which quickly had to be supplemented by the addition of a new wing; the later increase in staff, with afternoon admission of patients, and the establishment of a department for the supply of artificial dentures to the necessitous poor, will also be recalled to mind. It would, however, appear that the demand for dental operations and for scientific teaching necessitates the erection of a larger hospital. This is estimated to cost about £40,000, of which £3000 have already been promised by the staff and two or three friends interested in the hospital. If success in the past is a guarantee of success in the future, this sum should be quickly subscribed.

#### PROFESSIONAL OVERCROWDING.

NOWADAYS, and in every calling, we are liable to be constantly reminded that the ranks of workers are becoming inconveniently overcrowded. The statement has no doubt some foundation in fact, and it is one which conveys a very practical meaning to members of our own profession, which is at no time so overpaid that it can bear a lavish distribution of its emoluments. Fortunately the assertion admits of qualification. A comparison of medical practice in various large centres of industry, including the metropolis itself, has shown that the total number of resident practitioners has not grown in proportion to the increase of the general population. Overcrowding has in this case a relative rather than an absolute meaning. The number of workers is not disproportionate, yet work and incomes alike tend rather to restriction than to excess. We must therefore look to other causes than mere congestion within the profession itself to account for this fact. Among these we should probably include the development of specialism. Sufferers who would in a past generation have sought counsel of their nearest medical neighbour flock in crowds to some one or two who are supposed to hold the key to their constitutional secrets. The profession as a whole must lose in proportion, and often by no means justly. Another prime cause is to be found in the competition of hospitals. The abuse of charity evident for some time past in many such institutions has latterly undergone, it is true, considerable abatement under the exercise of

stricter methods of inspection, so that some relief of professional over-pressure may be looked for in this direction. Clubs and dispensaries again exert a similar but an even more deleterious influence. They are, as a rule, far too little subject to regulation as to the status of patients admitted to the charitable relief—for it is nothing else—which they afford. More than this, they are often administered, if not owned, by medical men themselves engaged in family practice, who for the sake of some supposed profit, either in means or in reputation, connive at impositions by well-to-do persons which are under any circumstances absolutely disgraceful. Such are some of the influences at work in every considerable centre of population, which, in spite of a correct statistical relation between the number of practitioners and of the local population, maintain a state which virtually tends to overcrowd and to starve out the former. We need hardly point out the fact that the true remedy for such conditions is to be found not among the regulations of licensing bodies or local authorities, but in the self-respecting decision of medical practitioners themselves.

#### IS SCARLET FEVER A BOVINE MALADY?

PRINCIPAL MCCALL of the Veterinary College, Glasgow, answers this question in the negative. In a recent address he analysed the evidence in the famous Hendon case of 1885, and in a more recent epidemic in Glasgow, due to the distribution of milk from two farms a few miles to the south of the city. In the latter case it was shown that the eruption on the cow's teats, to which the epidemic had been traced by some, had been present for twenty-four days, during which time the milk had been consumed by those on the farms and by the public in Glasgow without the production of scarlet fever, and as scarlet fever has a short incubative stage, it is clear that the cow's affection could not have been of that nature. Those who had become inoculated from the cow's teats also showed no signs of fever or eruption. Twenty-four days after the cow's teats were known to be affected a farmer's boy was seized with scarlet fever, which, however, was prevalent in two adjoining villages, and immediately afterwards the disease appeared in Glasgow in connexion with this particular milk-supply. Of course the milk-supply was stopped, and justly so; but, as Professor McCall points out, it is a serious matter to the farmer to cast to the dogs the milk of fifty-three cows. He suggests that dairy farmers should form a benefit society, with medical, veterinary and law officers, and that vendors of milk in the city should create a similar society.

#### PARALYSIS AFTER PNEUMONIA.

VARIOUS forms of paralysis have been described as occurring after a croupous pneumonia, but the complication is decidedly rare. Dr. Bouloche<sup>1</sup> has studied several such cases, which he divides into two groups, according as they occur early in the course of the primary disease or do not appear until the later stages.<sup>2</sup> Most of the former group are of a hemiplegic type; in rarer instances the paralysis is confined to a single extremity or region of the body. It occurred both in old and young people, appearing either after the physical signs and symptoms of pneumonia were fully developed, or completely masking the lung affection, so that the true state of affairs could only be discovered on post-mortem examination. This was particularly the case with old people in whom paralysis followed pneumonia, and was the more remarkable in that no local lesion could be discovered to account for the hemiplegia, as in seven out of seventeen cases which Dr. Bouloche found recorded in medical literature. The only pathological condition which could be detected in the brain after death in such cases was an atheromatous condition of the

<sup>1</sup> Thèse de Paris, 1892.

<sup>2</sup> Paralytiques précoces et paralytiques tardives.

vessels in the Sylvian fissure. The prognosis of this hemiplegic condition depends upon the age of the patient. In advanced life it is almost always fatal, but in young adults the outlook is much more favourable. The hemiplegia is often accompanied by aphasia, but as a rule it is transitory and recovery is rapid. In some of the fatal cases meningitis extending over the cerebrum was frequently met with, occasionally together, with softening of the cerebral substance from atheroma of the vessels. The second form of paralysis in connexion with pneumonia (paralysies pneumoniques tardives) does not appear until the convalescent period of the disease, and in the majority of instances not until the patient is almost well. One case, which occurred in a patient under the care of Professor Rendu, is recorded in detail. The symptoms closely resembled those of diphtheritic paralysis, paralysis of the palate and extremities, paresis of accommodation, loss of tendon reflexes, atrophy of muscles, reaction of degeneration, sensory disturbances; all these symptoms improved after three months and the patient finally recovered. As a rule, the paralytic symptoms appear about the tenth or twentieth day. Sensation is but slightly affected. The paresis affects the lower extremities more than the upper; sometimes the soft palate is also attacked, but the sphincters remain free. The pathological conditions which are the cause of this complication are uncertain, but the close analogy which they bear to diphtheritic paralysis would seem to indicate that a "toxic neuritis" is produced. The prognosis is almost always a favourable one. In a few cases after the appearance of the usual symptoms multiple sclerosis, meningo-myelitis, or a general weakness of the nervous system remained.

#### ENTERIC FEVER AT RUNCORN.

THE Runcorn Improvement Commissioners have thanked their health officer, Mr. F. McDougall, for his interesting report on enteric fever. With such action we have but to express concurrence, still we trust that something more than the thanks reported by the local press have followed the receipt of such a report. Mr. McDougall tells of widespread fever and of conditions which are an obvious cause of nuisance and disease, and he adds that these conditions, notably those attaching to the storage of huge quantities of filth and excreta near houses and schools, are due to a want of proper building by-laws. In a town like Runcorn a very strict limitation should be placed on the capacity of all filth receptacles, and the scavenging organised by the authority should be such as to prevent the need of anything but small receptacles for filth and refuse. There are now model by-laws dealing with all such matters, and authorities who have brought under their notice the fact that so fatal a disease as enteric fever is due to their failure to make proper by-laws incur a very grave responsibility unless they deal with the matter effectually and promptly.

#### ALCOHOL AND ACETIC ACID OBTAINED FROM PAPER.

It is quite within the bounds of possibility, as every chemist knows, to convert, by a series of simple chemical operations, an old linen shirt into sugar and alcohol. By merely immersing linen in cold, strong sulphuric acid, the celluline  $C_6H_{10}O_5$ , of which it is mainly composed gradually dissolves and, assimilating one molecule of water  $H_2O$ , resolves itself into glucose  $C_6H_{12}O_6$ . The glucose so formed may be recovered by neutralising the excess of acid with chalk, and from the product so obtained alcohol may be prepared by the ordinary process of fermentation. According to recent researches, acetic acid, too, can also be produced from similar materials—as, for example, paper pulp, Esparto grass &c., all of which contain celluline. The process, although apparently so simple, is somewhat different in detail. By digesting any

of the above substances, or, indeed, starch, sugar or other carbo-hydrates with alkali, such as caustic soda, a salt of the alkali, acetate of soda is formed. This can easily be recovered, and the product on distillation with sulphuric acid could be made to yield pure acetic acid, which it is well known is the acid of ordinary vinegar, in which it occurs to the extent of 3 to 4 per cent. Moreover, acetic acid  $C_2H_4O_2$ , being an oxidation product of alcohol  $C_2H_6O$ , it is possible by means of a reducing agent (a mixture evolving hydrogen) to convert it once more into alcohol. This conversion is only of theoretical interest, however, and of no practical value. Messrs. Cross and Bevan, who read a paper on this interesting action of alkali upon celluline bodies at a meeting of the Society of Chemical Industry last Monday, attached some importance to the process, as in all probability by its agency paper-makers might be in a position in the future to recover from their waste materials a product (acetate of soda) of value in certain industrial processes. Apart, however, from the possible practical value of these results, they are calculated to throw a new light upon the nature and constitution of that important cluster of bodies known as the carbo-hydrates.

#### THE CARDIAC GANGLIA IN ENDOCARDITIS.

DR. DMITRI KUZNETSOFF (St. Petersburg Military Medical Academy Dissertations, 1891-92, No. 70) has examined microscopically the nerve ganglia of the heart in twenty-three cases of acute and subacute endocarditis, comparing them with five control cases, and finds that the endothelial layer of the capsules of the ganglia is affected, the cells multiplying and swelling so as to form granulations. The changes in the nerve ganglion situated in the lower portion of the inner auricular septum are mainly due to the extension of the vascular granulation-forming process from the valves to the adipose tissue surrounding the ganglia. He has not found vacuolation of the ganglia, and he could not in general make out any connexion between changes in the muscular structure of the heart and in the ganglia.

#### DISTRIBUTION OF SENSORY DISTURBANCES.

THIS was the subject of a paper of much interest read before the Neurological Society of London by Dr. Henry Head, at its meeting on Nov. 17th. He set himself to show that the pain of visceral disease is distributed over definite regions, and is frequently associated with cutaneous tenderness. This tenderness reveals certain areas which correspond with those over which herpes zoster is distributed, and numerous graphic records of cases of herpes were shown, as well as diagrams in which the painful areas were indicated, bearing out this statement. It was also stated that each organ is definitely associated with a certain root area or with several areas, and when all the areas found to be tender in consequence of visceral disease are placed together on a chart of the body two gaps are seen, one on the arm and the other on the front of the leg or thigh. By tracing those tender areas to their origin in the cord, a means is found for indicating the segment of the cord from which the organ receives its sensory supply, and thus the course of the sympathetic fibres to the various organs can be mapped out. In this manner it is found that sensory sympathetic fibres arise from the first dorsal to the first lumbar roots inclusive; that no visceral fibres are given off from the second, third and fourth lumbar, and that again visceral fibres come off from the fifth lumbar and the first, second, third and fourth sacral. The fifth sacral and the coccygeal give no visceral fibres. Various conditions are referred to as altering the resistance of the nervous system, such as anæmia, pyrexia &c., so that localised pain or tenderness may become generalised. The sensory disturbances in hysteria were also referred to, and two varieties were distinguished—a cerebro-spinal and a psychical. The scope of the paper included a

discussion of several relative problems, for which there was not sufficient time. By common consent it was agreed that the subject was of such interest and the observations were so important that a profitable discussion of them in their various relations could only be undertaken when the members had had an opportunity of studying the views brought forward, and the evidence for them, when these were published. An adjourned meeting for the discussion is to be held, subsequently to which we hope to deal fully with the views which the paper embodies.

#### VILLAGE SANITATION.

MR. GEORGE DE'ATH of Buckingham is an ardent advocate of village sanitation; and as the result of the experience he has acquired both as to the sanitary circumstances of villages in his own county and as to the almost impossible task of securing for them proper sewerage, together with adequate water-supply, cleansing, control of buildings &c., he comes to the conclusion that a supervision of rural districts ought to be maintained by non-local medical inspectors connected with the central authority, that further powers of compulsion must be exercised and that the incidence of rating for sanitary purposes ought to be put on a more satisfactory footing. He also urges the necessity of means of adequate isolation of the sick and of institutions at certain central points where bacteriological and other similar work needed for purposes of diagnosis and of the adoption of successful preventive measures could be performed for the local health officers.

#### LARGE TUMOUR OF THE FRONTAL LOBE.

In a recent number of the *Medical News* (Philadelphia), Dr. Morrison gives a description of the case of a patient, first seen in 1886, when he was suffering from vague pains in the head, which were ascribed to syphilitic meningitis, and were relieved by iodide of potassium. Dr. Morrison lost sight of him and never saw him again until two days before his death in December, 1891. In the interval he had been in various hands, and had been in the Pennsylvania Hospital for a period of six weeks. From the somewhat fragmentary history it seems that in the summer of 1888 he had an epileptiform convulsion, and that the pains in the head returned with increased severity. They were worse on stooping. In August, 1889, he gave up his work, and about this time it was noticed that his speech was slower than formerly. Soon after leaving work his eyesight began to fail, so that he was unable to recognise persons or objects at some distance. When in the Pennsylvania Hospital he was in a condition of mental hebetude. The tongue was protruded straight and there was no paralysis. He had extensive hæmorrhagic retinitis in both eyes. There was no material change in his condition when he was seen by Dr. Morrison two days before death, except that he was feverish, with injected conjunctivæ and other symptoms of influenza. Next day he became comatose, and died that evening. At the necropsy the dura mater was found to be strongly adherent to the pia mater along each side of the longitudinal fissure. There was a large tumour in the left frontal region attached superficially to the dura mater, and apparently growing from it. This mass had occupied the greater part of the anterior fossa of the skull, and below it had invaded the left half of the cribriform plate of the ethmoid, so that there was a direct communication between the interior of the skull and the nasal cavity. The tumour extended backwards into the frontal lobe two and three-quarter inches. It was not adherent to the brain substance, but had apparently pressed the frontal convolutions backward, and when it had eroded the ethmoid it had apparently also destroyed some central tissue. After preservation in alcohol for five months the weight of the mass was five ounces, and one curious point about it is the

fact that there was a small exostosis on the inner aspect of the frontal bone, which formed a distinct indentation in the tumour. There was no evidence on the bone here of any external injury, but it may be that the irritation of the dura at one point by such an exostosis was a very important factor in the production of the growth. The tumour was a spindle-celled sarcoma, but the chief interest of the case lies in the absence of motor symptoms due to the growth—an absence which seems to confirm the current views as to the functions of the frontal lobes.

#### PROGRESS OF TYPHUS FEVER AT DUNDEE.

THE epidemic of typhus fever at Dundee shows some signs of abatement. In all twenty-eight cases have occurred in twenty-one houses. Of these twenty-one houses, six contain only one room, and thirteen only two. Only one five-roomed house was invaded. Pending fuller data, these facts show clearly the oft-established relationship between typhus fever and cubic space. Though half the cases were school attendants, the Dundee School Board have not agreed to the health officer's suggestion to close the public schools.

#### THE METROPOLITAN HOSPITAL SUNDAY FUND.

IN drawing the attention of our readers to the meeting of the Metropolitan Hospital Sunday Fund held at the Mansion House on Nov. 25th to consider the report of the Council, we noted that the date of the next annual collection of the fund was fixed for June 11th. We ought also to have stated that Archbishop Vaughan pointed out that, owing to the collection on behalf of schools belonging to the Roman Catholic denomination having been fixed for June 11th, it would be necessary for the Roman Catholic churches to make their Hospital Sunday collection on June 18th.

#### INFECTIOUS DISEASE AT LEEDS.

THERE are at present ninety cases of scarlet fever and forty-eight of small-pox under isolation at Leeds. Nine cases of the latter disease were removed during the week. It is said that there are a great many private sufferers from both diseases who have not been removed to hospital. Leeds at the present moment is in the unenviable position of being one of the very few large towns in England which has not adopted notification. The occurrences there will, it is hoped, cause an early removal of the stigma.

#### THE ORIGIN OF HÆMOGLOBIN.

WE look to comparative physiology and histology for much of our information on the origin of the blood-corpuscles, and quite recently considerable light has been shed on the subject by the researches carried on in both the phylogenetic and ontogenetic relations of these corpuscles. In the *Transactions of the Canadian Institute for 1891* Dr. A. B. Macallum<sup>1</sup> deals with the question of the origin of hæmoglobin of the fusiform corpuscles and of the hæmatoblasts in the blood of amphibia. Working with lake lizards (*Necturus lateralis*) and the larvæ of *Amblystoma punctatum* and examining the blood fresh, or fixed either in the fumes of osmic acid—1 per cent. solution for two hours—or by a saturated solution of corrosive sublimate or picric acid, or by Ehrlich's fluid (the only fixing reagents which he found serviceable), and staining with the various colour reagents usually recommended, he obtained most beautiful preparations, as a result of the study of which he concludes that the hæmoglobin of the blood-corpuscles is derived from the abundant nuclear chromatin of the hæmatoblasts. This chromatin, he considers, is an iron compound, the constant oxidation and reduction of which constitutes the chemical

<sup>1</sup> Studies on the Blood of Amphibia.

process underlying life. The fusiform cells of amphibian blood he maintains are derived from the blood-corpuscles—that they are in fact the remains of the broken up or destroyed red cells, the latter in this conversion losing the cell membrane and the greater portion of the discoplasm. The hæmatoblasts in amblystoma are probably the direct descendants of cells split off from the extreme ventral portions of the visceral mesoblast. Of course the most interesting part of the paper is that dealing with the origin of the hæmoglobin and with the iron in this compound. The importance of the use of freshly prepared ammonium sulphide in aiding in the solution of this question can from Dr. Macallum's evidence scarcely be over-estimated.

#### HEALTH OFFICERS AND NOTIFIED CASES.

THE function of the health officer with regard to cases notified to him is at all times a delicate one. He is *primâ facie* bound to accept the practitioner's certificate, even though he may know that this is based on incorrect diagnosis. At Megavissey, recently, a practitioner complained to the Local Government Board that the health officer had questioned his diagnosis in two instances of notification of diphtheria. The health officer has explained that he examined one case in his private capacity and the other at the request of the patient. The authority have accepted this explanation. We think it would have been better if the health officer had examined these patients in conjunction with the practitioner who certified. The case also illustrates the disadvantage of health officers being engaged in private practice.

#### SMALL-POX ISOLATION AND WORKHOUSE INFIRMARIES.

A CASE of small-pox has occurred at Keighley in the person of an inmate of the workhouse infirmary, the disease having been no doubt contracted from a tramp who three weeks ago was taken into the building suffering from small-pox and isolated in a room which communicates with the wards by a passage. At a special meeting of the guardians, and after consultation with the mayor, it was resolved to transfer the small-pox cases to the new model lodging house, which had already received two cases sent by the corporation. The proprietor of the lodging house, however, absolutely refused to receive any more cases, so that the danger of infection to other inmates of the workhouse infirmary remains as serious as before. It is a striking commentary on the ineffective state of sanitary administration and the absolute lack of isolation accommodation. This, too, in a town which rivals Leicester in its disregard of vaccination. An analogous question as to the use of the workhouse infirmary for the reception of cases of small-pox has arisen at Rotherham, where the medical officer has reported the likelihood of the disease spreading among the workhouse inmates. At the meeting of the guardians, when this report was received, it was stated that arrangements were in progress for the erection of an isolation hospital. In truth, the present prevalence of small-pox is doing much to demonstrate the weak points of sanitation in this country.

#### IS SCURVY A PARASITIC DISEASE?

DR. FREIRE<sup>1</sup> has come to the conclusion that scurvy is a disease probably of a parasitic nature. Having three cases under his charge (mother and two children) he took the opportunity of making the following experiments: After carefully sterilising the gums he drew off a drop of blood and inoculated, amongst other media, a peptone beef gelatine made with saturated solution of common salt; although

there was no growth in the ordinary media, in this one, at the end of about six days, there appeared a fine thread or film, almost like a flake of mucus, floating in the semi-fluid gelatine (semi-fluid because of the high temperature at which it was kept). At the end of fifteen days the gelatine was quite liquefied, and there were now numerous colonies of minute micrococci  $\frac{1}{1000}$  of a millimetre in diameter, each surrounded by a soft transparent material. This micrococcus was readily stained in fuchsin. Taking into account the fact that the hygienic conditions were bad in the case of the three patients, it can scarcely be maintained that the disease was distinctly infectious or contagious; but the fact that the organism was present in all three cases is interesting as suggesting the infective nature of the disease, and also as affording some evidence as to the cause of certain of the pathological conditions met with in scurvy, notably the hæmorrhages.

#### INFECTIOUS DISEASE AND NOTIFICATION AT LEITH.

MEASLES and scarlet fever are unusually rife at Leith. More than two hundred cases of the former disease are occurring weekly in the place and a score or so of the latter. A lively discussion as to the necessity for closing the schools has taken place in the Public Health Committee of the Council, and eventually a negative determination was arrived at. But a still more important question is shortly to be decided by the Town Council, being nothing less than the question of notification. At present a system of voluntary weekly notification is in force, but the Council will resolve at an early date whether the Act of 1889 shall be adopted or not. A sort of *plébiscite* of the medical profession has already been taken by an active journal in Leith. This has resulted in a well-nigh unanimous representation in favour of notification.

#### CONDITION OF THE BLOOD IN GASTRIC AFFECTIONS.

A CONSIDERABLE amount of uncertainty has hitherto existed in reference to the condition of the blood in connexion with gastric affections, especially in ulcer and malignant disease of the stomach, and authors differ greatly in their statements on the subject. Orterspey<sup>1</sup> has made some careful experiments in order to attempt to clear up these doubts, and the following are the results he has obtained: In nine cases of ulcer of the stomach the results were very uniform—diminution in the amount of hæmoglobin and in the number of red blood-corpuscles, these changes being particularly marked in those patients who had had hæmatemesis. These results of course correspond with the anæmic state so constantly met with in connexion with this disease, and all previous investigators have found the same condition. Out of twelve cases of cancer of the stomach, in one the blood was perfectly normal, in eight the number of red discs was diminished, in eleven there was a diminution in the amount of hæmoglobin present, in five there was an increase in the number of leucocytes, whilst in two, although the hæmoglobin was diminished, the red corpuscles were about normal in number. All these changes are neither characteristic of the cancerous cachexia generally nor of cancer of the stomach in particular, as they also occur to a similar degree in the course of many other affections. There is therefore no diagnostic difference in the blood to be noted in the two diseases, ulcer and carcinoma of the stomach. There is, perhaps, more value in the examination of the blood in doubtful cases, when there is uncertainty as to the case being one of malignant disease or chronic catarrh or a neurosis of the stomach, as the last two sometimes lead in extreme cases to the absence of hydrochloric acid in the gastric juice.

<sup>1</sup> Berlin. Klin. Wochenschrift.

## FOREIGN UNIVERSITY INTELLIGENCE.

*Gratz.*—Dr. J. Moeller of Innsbruck has been appointed to the chair of Pharmacology and Pharmacognosis.

*Kazan.*—Dr. L. Darkshevich has been appointed to the chair of Nervous Diseases.

*St. Petersburg (Military Medical Academy).*—Dr. Verigo has been recognised as *privat docent* in Physiology.

*Val-de-Grâce (Military Medical School).*—Dr. Vaillard has been appointed Professor of Epidemiology and Diseases of Armies, in succession to Dr. Kelsch.

## DEATHS OF EMINENT FOREIGN AND COLONIAL MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. M. P. Mansuroff, Emeritus Professor of Dermatology in the University of Moscow.—Dr. Alfredo Corradi, Professor of Therapeutics and *Materia Medica* in the University of Pavia.—Dr. L. Amabile, Honorary Professor in the University of Naples. (Obituary notices of the two last-named will be found in another column.)—Dr. Giacomo Giuseppe Alvisi, member of the Italian Senate.—Dr. Friedrich Herrman, formerly senior physician to the Obukhoff Hospital, St. Petersburg, in his eighty-second year.—Dr. Geo. Ross, Professor of Medicine in the McGill University, Montreal.—Dr. Berry, one of the Bath Physicians at St. Moritz.

ON Wednesday last the committee appointed by the Chamber of Shipping of the United Kingdom and the Shipping Federation, with the approval of the Board of Trade, met to consider the question of the quality &c. of the food supplied to the mercantile marine. At this meeting the preparation of a draft scale of victualling was completed and next week the evidence of practical men on the general subject will be taken.

THE ceremony of laying the foundation-stone of the Clarence wing of St. Mary's Hospital has been fixed for the 17th inst. The Prince of Wales, accompanied by the Duchess of Fife, will arrive at the hospital at half-past twelve, when his Royal Highness will be received by the Duke of York, as President of the hospital, and the Duke of Cambridge. The Duchess of Fife will receive purses in aid of the Clarence Memorial Fund.

THE new premises of the Royal Eye Hospital in Southwark will be opened on the 15th inst. by the Duke of York. He will be received by the Duke of Cambridge, Sir Joseph Lister, Admiral Sir Harry Keppel and other friends of the institution.

MR. R. E. SPRAGUE ORAM has been appointed Her Majesty's Chief Inspector of Factories in succession to Mr. Whymper. Mr. Oram acted in 1889 as travelling secretary to the House of Lords' Committee on Sweating.

THE Senatus of the University of Aberdeen have appointed Professor Matthew Hay, M.D., for a further period of four years as one of their representatives in the University Court.

MR. H. H. CLUTTON, M.A., M.B., F.R.C.S., has been appointed by the Senate of the University of Cambridge an additional Examiner in Surgery for the present term.

MR. G. A. WRIGHT, B.A., M.B. Oxon., F.R.C.S., has been appointed an Examiner in Surgery for the Second M.B. Examination of the University of Oxford.

## Pharmacology and Therapeutics.

## EFFECT OF BITTERS.

DR. P. TERRAY, after investigating the effects of bitters upon the stomach of the dog, comes to the following conclusions: Gentian is the most powerful stimulant to the automatic movements of the stomach, and next in order come ceratine, conduragine, taraxacum, sulphate of quinine, and, last of all, quassia. Absinthe in small doses diminishes the movements of the stomach, and in larger doses arrests them entirely. Calumbine and strychnine excite the stomach until a condition of tonic contraction is reached. Picrotoxine has no decided effect. Ceratine increases the peristaltic movements of the bowel in addition to those of the stomach. From these results it would appear that bitters can be used with advantage in cases of atony of the stomach with a moderate amount of dilatation, and that ceratine can be prescribed when purgative effects are desirable.

## ICHTHYOL IN GONORRHOEA.

Until recently ichthyol has been but little employed in gonorrhoea, but from a series of observations made by Dr. Jadassohn on some 200 cases occurring in the out-patient department of the Breslau Hospital and in private practice, and published by him in the *Deutsche Medicinische Wochenschrift* (Nos. 38 and 39), it would appear that in many instances it proves a very valuable local remedy. In anterior urethritis in the male subject injections gradually increasing from 1 to 5 per cent. in strength and in posterior urethritis from 1 to 10 per cent. may be given. In the female subject the cervical canal and the urethra will even bear applications of the undiluted substance, but there does not seem to be any advantage in employing this or a very strong solution. The addition of 10 per cent. of glycerine was made to the applications used for female subjects. A 1 per cent. solution exercised in most cases a very decided anti-gonorrhoeal action, the gonococci disappearing generally more quickly than with other methods of local treatment, such as injections of resorcin, corrosive sublimate and permanganate. In a certain number of cases, however, it, like other remedies, failed. Again, in some few cases the gonococci, after having apparently vanished, reappeared, but these were more exceptional than under other methods of treatment. A good many cases which had been unsuccessfully treated with nitrate of silver were cured with ichthyol, and some in which ichthyol failed were cured with nitrate of silver. Attempts to combine ichthyol with resorcin, boracic acid &c., were not very successful; but Dr. Jadassohn found that some cases both of anterior and posterior urethritis could be remarkably well treated by alternating injections of ichthyol and nitrate of silver.

## NEW DRUGS.

Dr. Domingos Freire (*Sur un Alcaloïde et deux Principes Résinoïdes Extraits de la Jurubêbe. Rio Janeiro: Imprimerie de Pinheiro & Co., 1890*) describes an alkaloid and two resinoid principles obtained from the jurubêba or *solanum paniculatum*. The alkaloid, the method of preparation of which he gives—jurubêbine—in the form of a hydrochlorate when injected in very minute quantities into a small bird produced marked tetaniform convulsions, preceded however by a semi-lethargic condition in which there was contracture of the extremities; these convulsions ended in death. Of the resinoid substances obtained jurubêbine has an extremely purgative action, whilst the second, jurubêbin, a resin soluble in potassium hydrate is non-active. Dr. Domingos Freire considers that the poisonous alkaloid is found especially in the leaves of the plant and that like strychnia it exaggerates or stimulates the excito-motor action of the cord. The purgative resin obtained from this same plant he looks upon as probably analogous to podophyllin.

## THE SALICYLATES IN PLEURISY.

The salicylic treatment of pleurisy, which was first recommended by Aufrecht nine or ten years ago, has recently found considerable favour amongst Swedish physicians, Professor Edgren having employed it in the Serafim Hospital in Stockholm, and Dr. Koster in the Sahlgren Hospital in Gothenberg with great success. In cases where the effusion is quite recent salicylate of soda given in divided doses of from forty-five to sixty grains per diem is stated to cause rapid absorption, so that aspiration is not required, or if practised a portion only of the fluid need be removed;

The pyrexia disappears simultaneously with the fluid. When other serous membranes, as the pericardium or the peritoneum, become affected the salicylate acts in an equally beneficial manner on them in causing the absorption of the effusion. In certain of Professor Edgren's cases, it is true, the drug failed to produce any marked effect either on the effusion or on the temperature, but it is not unlikely that in these cases the pleurisy was really secondary and of tubercular origin, though in other cases of undoubted tubercular pleurisy the salicylate was by no means without effect.

#### HYDRASTININ.

According to Dr. Faber hydrastinin, when given during labour, though it sets up uterine contractions, does not expedite the expulsion of the child, but rather retards it. The pains, which are of a character similar to those produced by ergot, are sometimes very protracted, lasting in one case for as much as a quarter of an hour. In metrorrhagia, whether due to endometritis, myoma, or tumours in the uterine appendages, hydrastinin has proved valuable, and is best administered hypodermically, the dose being about five centigrammes.

#### A NEW SUBSTITUTE FOR COCAINE.

The acetamide of eugenol—which is contained in oil of cloves—has recently been prepared; it occurs in crystalline form, and appears to enjoy the property of producing local anaesthesia in a very high degree. It may be used similarly to cocaine for this purpose, and, as it has no caustic action and is an energetic antiseptic, it may be found to be even superior to cocaine for minor operations on the mucous membranes.

#### THE ALKALOIDS OF COD-LIVER OIL.

According to M. Bouillot, the alkaloids of cod-liver oil, given in quantities of from 2 to 3½ grains during the twenty-four hours, have a distinct diuretic action, increasing not only the quantity of urine, but that of urea. As had previously been stated by MM. Gautier and Mourgues, who studied their effects on animals, M. Bouillot found that they cause a marked increase in intra-organic oxidation, the oxidation of the leucomaines being rendered nearly complete and the toxicity of these bodies being diminished. It therefore appears to him that the alkaloids of cod-liver oil are likely to be of considerable value in therapeutics.

#### PHARMACOLOGY OF BROMIDE OF ETHYL.

Dr. Ginsburg (St. Petersburg Military Medical Academy Dissertations, 1891-92, No. 111), writing on the pharmacology of bromide of ethyl, states among the results of his numerous experiments on dogs and rabbits that in small doses it increases the irritability of the heart muscle, but in large doses diminishes it; thus in the former case the excito-motor ganglia or accelerator nerves are stimulated, while in the latter the irritability of the heart muscle is lowered and the frequency of its contractions diminished. Bromide of ethyl also lowers the blood pressures, paralysing the peripheral vaso-motor nerves. With large doses the heart takes a share in lowering the blood pressure. The drug does not appear to have any effect on the pneumogastric or on the vasodilator nerves, either central or peripheral.

### A NOTE ON THE FORTHCOMING CONFERENCE ON CHOLERA IN ST. PETERSBURG.

THE following brief account of the nature and object of the conference on cholera to be held in St. Petersburg towards the end of December may be of interest. The purpose of the conference is to decide on the measures to be adopted to meet the fresh outbreak of the disease that is fully expected to occur next year, more particular attention being paid to the special measures demanded by varying local conditions. With this object a circular letter was addressed on Oct. 30th (Nov. 11th) by the Minister of the Interior to the Governor of each province (or "government") throughout the country, requesting him to select one or two physicians who had had a close personal experience of the epidemic during the past summer to act as members of the conference. The opening meeting will take place on Dec. 13th (25th), and it is expected that the conference will last for from five to seven days. The Ministry has undertaken to bear all the travelling expenses of

the members, who will receive a sum of two roubles each per diem for lodgings, and an additional daily payment of three roubles during the time they are in St. Petersburg. In order that the medical men selected may have every means for forming an opinion on the questions to be discussed, the Medical Department of the Ministry has enjoined its local representatives to furnish each member with all the information at their disposal, such as medical reports, bulletins on the course of the epidemic, charts, plans, results of examinations of water and of soil and the administrative and local arrangements made for meeting the epidemic.

The programme of the conference is already in print. It sets forth the points to be discussed in the following order: (a) Measures for improving the sanitary condition of inhabited localities: (1) The chief features of localities with water-supply of unsatisfactory quality and the possibility of providing them with harmless water; (2) the nature and means of cleansing cesspools; (3) organisation of the sanitary supervision. (b) Measures directed against the introduction of infection and the preliminary arrangements for meeting the forthcoming epidemic: (1) The means of determining the first case of cholera and the organisation for registering the cases and deaths; (2) the means for isolation and carriage of patients; (3) the various systems of supplying medical aid and their relative efficiency in combating the epidemic; (4) the rôle of sanitary overseers and the instruction of the inferior members of the service in dealing with the sick and in disinfection; (5) the methods of disinfection that have appeared most suitable and efficient; the disinfection of dejecta, houses, utensils &c.; the cost of disinfection and the possibility of substituting for it destruction (by burning); (6) the means of disposal of refuse and the methods of disinfecting in villages; (7) which is preferable, the removal of the sick to hospital or their isolation at home, where all precautionary measures can be taken?

A second form of considerable interest has been circulated among members of the conference. It contains in full detail the programme of the Government Report on the Epidemic of 1892, which it is hoped will be issued in the course of a few months. The main heads of the report will be the four following:—Preliminary information; the cholera epidemic; the measures for meeting it; and finally, observations bearing on the symptomatology, treatment, etiology and prophylaxis of cholera. The information will further be grouped under a large number of subdivisions, the enumeration of which is sufficient to cover nearly two sides of a foolscap sheet of paper. With the elaborate machinery at the disposal of the Russian Government for obtaining information and statistics from every part of the country the report will, it is expected, be full, thorough and accurate, and its publication will be looked forward to as an event of no little interest and importance.

## CHOLERA.

#### CURRENT NOTES, COMMENTS AND CRITICISM.

WHEN a full account has been rendered of the cholera epidemic of 1892 the results will be so lamentable as to appear little short of appalling. It is difficult at present to estimate the aggregate loss of life it has caused, and to realise all the sickness, misery and destitution it has entailed. The events and figures making up the history of the epidemic, which we have chronicled week by week, in reality fail to represent the facts adequately, much less to afford a true picture of what have been the sufferings of the various populations of the different countries invaded by the disease. Among no people, perhaps, have these been greater than among the Jews in Poland. During the three months that cholera was raging in the Governments of Lubin, Siedlec, and Radow, for example, the death-rate was terrible, and the destitution consequent thereupon calamitous. A correspondent, writing recently in the *Jewish Chronicle*, says that in the case of Lubin 90 per cent. of the victims were Jews who inhabit the unhealthiest quarter of the town. The epidemic has now passed away, but has left terrible traces behind it. Many thousand families are described as being without bread, without a roof, without clothes, and deprived of all means of subsistence. Apart from the effects of the disease, it is to be feared that the application of ill-considered measures for its repression,

and a totally inadequate provision for coping with it, have greatly added to and aggravated the sufferings of the unfortunate people. Death, quarantine, disinfection, stagnation of commerce and suspension of trade have placed the poor in a state of misery which defies description. As so commonly happens it is not exactly known when cholera first appeared in Lubin; but it reached its full intensity about the middle of August. The town has about 40,000 inhabitants. For several weeks the deaths from cholera reached nearly eighty per diem. On the lowest calculation 2500 deaths occurred in August and September, and the disease almost exclusively attacked one portion of the town and a certain class of its proportion. Of the total number of deaths about one-tenth only occurred in the upper town, and this would give for the 15,000 residents in the lower town the proportion of one death in six. At Miedzzyzec, a town of 8000 inhabitants, the mortality from cholera was 300, and at Miechow 350 died out of a population of 2000. The method of procedure adopted at Lublin on the occurrence of a death from cholera was for the police to proceed to the house in which the death occurred and turn all the people out, and place seals upon the doors. They were not allowed to remove any of their clothes or belongings for fear of spreading infection, and were at once transported to large wooden huts erected at some distance from the town without any other sort of provision having been made for them. The starvation, sickness and misery that followed may be readily imagined. A spirit of charity and solidarity, which has always been a distinguishing feature of the Jewish race, was soon manifested by some of the richer Jews, but their efforts and resources in aid of the poorest sufferers are exhausted, and with the presence of winter the prospect is a pitiable one.

There is, happily, but little to chronicle regarding cholera nearer home. According to official reports there were four deaths from that disease in Holland during the past week. A death from cholera is also reported at Brussels. Several cases of choleraic disease are still under treatment at the St. Jean Hospital at Bruges.

Although an occasional case is reported in Hungary and France, cholera—at any rate as an epidemic disease—has disappeared for the present. Several cases have recently occurred in the town and suburbs of Epernay. It is perhaps worthy of note that Epernay is on the line of communication between Paris, the Ardennes, Dinant and Namur. At Dinant it is alleged that there were some cases of cholera last summer, although the fact of their occurrence was skillfully concealed. At Calais some excitement was caused lately among the maritime population by the removal to hospital of five persons, all of one family, who were attacked with choleraic symptoms. In view of its possible return next spring in the province of Saratoff it has been decided by the authorities at St. Petersburg to supplement the staff of the sanitary service by a considerable increase in the number of officials.

According to the latest intelligence the disease has broken out again in a virulent form in several villages of the province of Poltava, and the Russian authorities are continuing to prosecute various measures in anticipation of a recrudescence of cholera in the spring. At the last meeting of the Medical Society Surgeon-Colonel J. B. Hamilton read a paper on the epidemic progress and causation of cholera mainly based upon observations and experience of that disease in India, which led to an interesting debate, an abstract of which is published in our reports of medical societies for this week.

We are glad to notice that at a recent meeting of the London Common Council the exertions of the Port Sanitary Committee and Dr. Collingridge in endeavouring to protect the Port of London against cholera were fully recognised. Dr. Collingridge in particular was indefatigable and rendered very valuable services to the public.

## CHOLERA IN FRANCE.

(FROM OUR SPECIAL CORRESPONDENT.)

### A VISIT TO HONFLEUR.

*The Water Drunk on English Ships.—The High Death-rate.—Cholera Patients and Rum.—Chaos in Sanitation.*

THERE is no regular water-supply at Honfleur. A number of springs exist within the town and some at a little distance from it. The public derive their water from these

springs, but some of the fountains were constructed so long ago that all record has been lost. There is the water, but even the town authorities are unable to say whence it comes. There are five principal springs, and the one that supplies the shipping with water is known as the Source St. Leonard. This spring is somewhere on the inland side of the old St. Leonard Church and the theatre. The church has a fine portal, built in the sixteenth century, but underneath the water has formed a small subterranean lake which renders the church so damp that the ornamental painting has been spoilt. It is supposed that the water comes from the hill Côte Vassal, which is about seventy metres high and is close at hand. Red flint, a little clay and iron and a large quantity of lime compose the soil of this hill. The rain falling on the surface of the hill dries very quickly and helps to form the St. Leonard spring, but no one knows where this spring is situated. The fountain, however, which gives the water is by the church, but on the other side, so that the water has to pass under the church before it reaches the fountain. This fountain is in the very centre and low-lying part of the town and is surrounded by public washing tanks. Here dirty linen is daily washed, and there is no saying to what extent the splashing of the dirty water may filter through the earth into the drinking water below. Apart from this, before reaching the fountain the water could be contaminated by filth from the numerous surrounding houses. Samples of the water have recently been sent to Paris for bacteriological examination. From this fountain near the St. Leonard Church, pipes convey a portion of the water to a little fountain on the quays near to the mooring station of the Newhaven boats, and it is from this secondary fountain that the sailors usually take their supply to fill the tanks on board the English ships. May not the bringing of such water into English ports be far more dangerous than the arrival of travellers from abroad?

There have been twenty cases of cholera at Honfleur, most of them occurring at the end of August and during the month of September, in the Hochas and St. Nichol quarters. In the latter district there is an important public fountain. The water comes through some very old pipes, partly made of wood and tarred over. These pipes are supposed to be from 200 to 300 metres long, but they are so ancient that nobody can tell in what direction they are laid or where the spring is that fills them with water. To find out it would be necessary to dig up several streets. On one occasion, for instance, a house near the port was flooded. The cellars were full of water and no one could imagine whence it came. At last it was noticed that a fountain some distance off, and near the chief post-office, did not run as plentifully as usual. An investigation was made, with the result that a broken pipe was discovered; and when this was mended the cellar was no longer flooded. The water had passed under two streets and two blocks of houses to reach this cellar. The higher districts of the town have no fountains. All the pumps or fountains or springs are in the low-lying portion of Honfleur—that is to say, precisely where the water is most exposed to the danger of contamination. Where there are pipes the water is not under pressure. The pipes often leak and, as there is no pressure from within, foul water can enter the leaking pipes from without.

If the water was derived from the subsoil of a perfectly clean, well-drained and healthy town there would be less fear of contamination; but, as already stated, Honfleur is an exceptionally unhealthy and dirty place. Fortunately there are only 9726 inhabitants; but in the last ten years the deaths were not far short of a third of the population. There were from 1882 to 1891 no less than 2901 deaths, of which 1456 were of persons under twenty years of age. The irregularity in the annual number of deaths suggests the frequent occurrence of epidemic disease. The deaths for each of the ten years mentioned were, in due order, as follows:—347, 301, 252, 275, 329, 283, 326, 334, 222 and 332. Allowing for fluctuations of the population, this gives a death-rate of 29 to 30 per 1000 per annum. When it is considered that the population is less than 10,000, that the town is swept by fresh sea breezes, is beautifully situated and has every facility for good sanitation, such a death-rate can scarcely be described as otherwise than preventable. A few elementary measures of hygiene would in all probability reduce the death-rate by one-half.

Not only is there no regular water-supply at Honfleur, but there is also no drainage system. A few sewers exist here and there, but no one knows exactly where they are or how many there may be. There is no plan of the drainage or of

the water-supply; in fact, the question seems to be entirely ignored. In most of the houses there are pails, and there is a contractor who undertakes to empty these pails once a month, if paid 12s. a year. But a very large number of the inhabitants object to pay the 12s. They simply carry their pails downstairs themselves and empty the contents into the port amidst the shipping. The water thus polluted is then used to wash the decks &c. of the ships. Of course the principal sewers also fall into the port, and still further help to corrupt the water in which the ships float while they are loading butter and poultry, fruit and eggs for the British market. There is no law compelling the householders to empty their pails or *tinettes*. They may or may not employ the contractor, just as they think fit; the pails may remain in the house and overflow with filth just as the people choose. The idea of enforcing cleanliness does not seem to have dawned upon the authorities. Even when the contractor does come to remove the contents of the pails or of such cesspools as exist he sometimes employs a tub cart which leaks, and thus befouls the streets through which it passes. In many houses there is neither closet, cesspool nor pail, but everything is simply emptied into the gutter in front of the door. This is often done in broad daylight in the principal streets, and before numbers of people. From the gutter this filth, in the course of time, finds its way to such sewers as exist, and at the sewer mouth mixes with the offal from butchers' shops. These sewer mouths are so badly constructed that they get choked up and occasion vile odours. When, as the result of a storm or some special rush of water, the sewer mouth is cleared, the filth travels slowly down to the port. The pneumatic system of emptying cesspools is not applied, nor is any attempt made to burn the foul gases that escape from the cesspools. By the side of these cesspools—and no serious measures are taken to prevent the cesspools from leaking—may often be found a spring of water. Apart from the public fountains, a great number of persons have springs in their own gardens and drink the water. There are, in fact, springs of water in all directions, every one of them more or less exposed to contamination, and everybody is allowed to drink what water he pleases without any regard to the danger incurred.

The western portion of the town faces a long beach, where an embankment could be easily constructed to hold the tide in check and a fine site could be thus created either for building purposes or for an esplanade and pleasure grounds. At present, however, this beach has been converted into a wilderness covered with the refuse of the town. Here is thrown the "soft core" and the "hard core" from the street sweeping. Here are to be found ankle-deep—sometimes knee-deep—such refuse as bottles, broken crockery, tins, dirty straw, dead animals, shrimp skins, fish bones and offal, cabbage stumps, household refuse of every description, and an enormous amount of apple refuse from which the juice has been extracted to make cider. To keep all this moist, to ensure its active fermentation, all along the remains of what used to be the city sea wall there are large numbers of drains or small sewers pouring forth slop-water, urine and fecal matter. The pure sea breezes that should give health and vigour to the inhabitants of Honfleur pass over this festering mass of decomposing organic matter before they reach the town. It is said that some orders have been issued forbidding the throwing of refuse on this beach. If so, the orders were given out only as a matter of form; they are in no wise observed. I have been the whole length of this beach; every obnoxious article mentioned I have seen; and while I was on the spot some carts with refuse came and unloaded on the beach in my presence.

The first case of cholera occurred on Aug. 27th. A man who had been to Havre was taken ill very suddenly and died as he was being conveyed to the hospital. Dr. Massard, the "doctor for epidemics," being fully aware of the insanitary condition of Honfleur, and fearing that the epidemic would spread very rapidly in such a town, adopted the most rigorous and extreme measures possible. He caused everything belonging to the victim to be at once burnt; his clothes even, and his furniture, were destroyed by fire; then he gave orders that the passenger boat from Havre should be thoroughly disinfected. It was forbidden to bring over fresh vegetables from Havre, and no dirty linen was allowed on shore from the Havre boats. Nevertheless, other cases occurred at Honfleur; eighteen patients were treated for cholera at the hospital and nine died. The deaths were very sudden, accompanied with all the symptoms of Asiatic

cholera, notably what Dr. Massard described as the blue or "toad skin." The patients for the most part came from poor quarters of the town; but there are other quarters of Honfleur, even more poor and more insanitary, where no cases of cholera occurred. Most of the patients were known to be drunkards, yet, much to his surprise, Dr. Massard noticed that when ill they manifested a strong repugnance for the rum that was prescribed. On the other hand, the patients who were not drunkards took the rum given to them without any difficulty. Apart from cholera, typhoid fever is now prevalent at Honfleur, and at all times there has been a great deal of fever of a malarial type, necessitating a large consumption of quinine.

In spite of all these facts it is said that Honfleur is too poor to attempt any sanitary improvements. The timber trade is gradually leaving the town, and many Scandinavian ships now go to Dieppe, Havre and Rouen. One large timber-sawing factory has been closed, and this means a decrease in the municipal receipts of £720 per annum out of a total of £5500. Yet in spite of this the Municipality has recently constructed a huge new dock, which in face of the decreasing trade was quite unnecessary. Had the financial liabilities incurred for this new dock been contracted for purposes of providing a good water-supply and good sewers the town would soon have acquired a better reputation, and this would have materially helped to bring the trade back. At about four miles' distance from the town an ample supply of pure water could be obtained and delivered at Honfleur under pressure. The cost of the works necessary is estimated at £20,000; but the Municipality does not seem to understand the importance of such an undertaking. In spite of the high death-rate an impression prevails that Honfleur is a very healthy place. Notwithstanding the efforts of a few local reformers—notably Dr. Rachet, who is a municipal councillor, and Dr. Massard, who as "doctor of epidemics" represents the central government—nothing will be done unless strong outside pressure is brought to bear. This might be achieved, on the one hand, by the French Minister of the Interior and, on the other hand, by the English shipping companies, who so largely contribute to maintain the trade of the port.

## LEPROSY IN BRITISH GUIANA.

THE experience of Dr. Barnes, as medical superintendent of the public leper asylums of British Guiana, does not lead him to regard leprosy as contagious—at least under ordinary conditions. In the "British Guiana Medical Annual and Hospital Reports," just published, he says:—"At the Public Lunatic Asylum there have been for many years several lepers living in a ward in association with other patients and no spread has occurred. Similarly, at the Trinidad and our own leper asylums no healthy person employed as nurse, doctor, or in any capacity has ever developed the disease. Further, upon taking charge of the leper asylums I found at Gorchum a dozen children, varying in age up to fifteen years, quite free from signs of the disease, although born of diseased parents and living with and as lepers. I may also mention particularly the case of a man employed for twelve years in washing the inmates' clothes at Mahaica. He is still quite healthy. The asylum at Molde, founded over 150 years ago, shows the same state of affairs. No doctor or nurse has ever developed leprosy. Doctors and trained nurses should enjoy perhaps some immunity, as they may be expected to be cleanly in their habits; but this factor scarcely exists among the employes at our own asylum, their ablutions being confined chiefly to a careless rinse with a few ounces of water."

Dr. Barnes is opposed to the compulsory segregation of lepers, thinking that the stamping out of the disease may be expected to be accomplished by the elevation of the people. As regards treatment he does not believe there is any specific; the chief thing is to make the leper take care of himself. If he leads a quiet, steady life, avoids burning or cutting himself, and cleanses any ulcer that may form, resting the hand or foot on which it is, he may look for a comparatively comfortable existence. In some cases of leprous fever, however, Dr. Barnes has seen salicylate of soda act like a charm. In operations on lepers he has found hemorrhage to be slight, contrary to the experience of some other writers. Dr. Beaven Rake's plan of

cutting through perforating ulcers he considers the best treatment for such cases. As to the question of heredity he says: "In spite of the habitual denial of hereditary taint amongst the creoles, I have been told by some of the old inmates of the asylums that almost all the creole inmates have or have had relatives who were leprous. This I intend to work out, as fully as possible, to verify or disprove the assertion. My own experience shows that the more I learn of the family history of the inmates the more hereditary taint is revealed. Amongst the general population of the colony hereditary influence is held with at least as great tenacity as is contagion. I know that it is frequently sufficient to frustrate projected marriages even amongst the educated classes. Of course, the occurrence of the disease amongst several members of a family might arise as well from contagion as from hereditary influence."

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Lanark County.*—Dr. James M'Lintock has submitted to this County Council just such a report as is wanted as the first of a series of annual reports. It takes up under a series of headings all the points which are needed in order to serve as a basis of future action. Whether statistics or physical conditions of the district are concerned; whether the different circumstances as to sewerage, water-supply and disposal of excreta are in question; or whether the more incidental considerations such as hospital accommodation, river pollution, inspection of trades, dairies &c. are involved: all these various matters are dealt with in so far as their bearing on public health is concerned. There is plenty of sanitary work to do in the county, and Dr. M'Lintock is fully conversant with both the existing state of affairs and with the lines on which work should be carried out in the future. His report deserves wide circulation throughout the county.

*Woolwich Urban District.*—This extra-metropolitan district had in 1891 a gross death-rate of 22.4 per 1000 and a zymotic rate of 2.8 per 1000, the latter rate being mainly the result of deaths from whooping-cough, measles and diarrhoea. In this connexion Dr. W. R. Smith urges that measles should be added to the list of notifiable diseases and that he should thus have an additional means of taking steps to prevent the attendance at elementary schools of children coming from houses in which that disease exists. He at the same time points out that the notification of erysipelas is without apparent benefit. No less than some 5000 cases of this affection were notified in London last year, and the Local Government Board hold that it is of such concern to lying-in women, to vaccinated infants and to persons requiring surgical operations that they cannot take steps to remove it from the Notification Act. House-to-house inspection is progressing in Woolwich, and some action is being taken as regards the housing of the working classes. But Dr. Smith states that the condition of the houses in Woolwich is one that causes him considerable and continuing anxiety, more particularly in view of the mortality returns from phthisis and allied disorders.

*Blackpool Urban District.*—Dr. A. J. Anderson gives the corrected death-rate for 1891 as 18.2 per 1000, and he at the same time points out that owing to the sudden influx of visitors of all classes the population, on which the rates are calculated, run risks quite in excess of that commonly attaching to places of a like number of inhabitants. The infant mortality remains very high—namely, 181.9 per 1000 births, although there was no summer diarrhoea due to excess of temperature. The heavy rate of deaths amongst infants is largely set down to neglect amongst mothers, who have to look after visitors rather than care for and suckle their babies. After discussing the working of the system of compulsory notification, Dr. Anderson reports on the opening of the new isolation hospital on July 7th. The old sanatorium received 11 patients in the first six months of the year; the new one received 51 in the second half of the year. The increase since July may have more than one explanation, but it is noteworthy in connexion with the provision of a proper instead of a very unsatisfactory hospital. House-to-house inspection has now been maintained for four

years, and much good has resulted. Details of the work are given, and it is clear that the accumulated results must be beneficial to the town and increase its prosperity.

*St. Helens Urban District.*—The annual rate of mortality was, last year, above the average, and this was mainly due to influenza; but the excess of deaths maintained in St. Helens and the failure to secure a more substantial abatement in its average are remarkable. Mr. M'Nicoll gives the rate for 1892 as 25.4 per 1000. Infant death is great in amount, and the mean zymotic rate is high. The latter is due to ignorance and carelessness, and to the breeding grounds of disease which are maintained in the borough by reason of its deep and filthy middenstends. The various causes of disease are discussed at some length, and then a description is given of the sanitary work of the year. Some really important work has been carried out, notably the construction of a new intercepting sewer; houses unfit for habitation have in some cases been dealt with, and a decision has been come to not to take a retrograde step which would involve relapse as regards refuse removal, merely on the score of expense. During the year eighty-nine patients were admitted into the isolation hospital, the largest number of admissions being cases of enteric fever. It is satisfactory to note that an assistant medical officer of health has been appointed, the holder of the new office being Dr. John Robertson of Edinburgh; and Mr. M'Nicoll testifies that his labours are already telling forcibly on the sanitary organisation of the town.

*Wem Rural District.*—Mr. Cecil A. Corke gives an account of the measures adopted in face of an epidemic of measles. He found that the mere exclusion of scholars from infected houses served no sufficient purpose, but when school-closure was resorted to the prevalence became controlled. The authorities of Sunday and other voluntary schools consented to act in concert with the elementary schools as to closing; but Mr. Corke considers that the power to close such schools should go hand in hand with that exercisable over the public elementary schools. The death-rate during the year was 16.9 per thousand; a new cemetery site has been decided on; care has been bestowed on water supplies, and nuisance inspection has been maintained. But the district needs some means of hospital isolation and the compulsory notification of infectious diseases ought to be adopted.

*Teignmouth Urban District.*—Dr. Cecil Piggott, after discussing the meteorology of 1891, explains that the corrected death-rate for the year was 17.7 per 1000 and that the zymotic rate was very low. The causes of death are considered in the report, and the subject of the etiology of influenza is entered into in some detail. The local medical profession have strongly pressed on the authority the need for an isolation hospital, and this attitude receives Dr. Piggott's support. Indeed, a place like Teignmouth, professing to be a health resort, has a duty in respect to the isolation of first cases of infectious diseases quite in excess of that of other sanitary districts which make no such profession. Evidently excellent work by way of systematic inspection is in progress, house drains seem to be effectually tested and remedies are applied where needed. The water-supply ought to be a constant one and surface wells need to be abolished. On the whole, the report tells of good work well sustained throughout the year.

*Isle of Wight Rural District.*—Dr. Joseph Groves once more gives a very complete report on the greater part of this island, a district to which many look with interest. Last year the general death-rate was 16.5 and the zymotic rate was 1.6 per 1000. In dealing with the infectious diseases each parish is separately considered, and credit is given to the notification system for supplying valuable information. No means of isolation have been provided, but since the issue of the report some preliminary measures have been taken which may result in action as to this important matter. By-laws and questions of scavenging have been considered at length, but decided action is still awaited. There is also need of a better provision of water, the more especially because in some well-known localities which are frequented by visitors shallow and polluted wells exist, and ill-kept rainwater is still resorted to. This subject is dealt with at considerable length by Dr. Groves, and the sanitary authority can certainly not complain that they have not received full information as to the places where action is needed. Much the same may be said as to defects of sewers and drainage. Indeed, we are forcibly struck with the fact that whilst detailed information has again and again been supplied to this authority as to the lines on which effective sanitary administration should proceed, so little is done to remedy defects that ought to be obvious to all. Difficulties must be admitted to exist,

especially as to water-supply; but the account of the sanitary state of the contributory places of this otherwise attractive rural area is by no means pleasant reading; and it ought to call forth much more energy than has yet been apparent on the part of the authority.

*Bradford Urban District.*—The vital statistics of this important borough are discussed at some length by Dr. Arnold Evans, who records the general death rate for 1891 as 22·0 and the zymotic rate as 2·3 per 1000 living, whilst the infant mortality was at the rate of 181 per 1000 registered births. Whooping-cough, scarlet fever, and diarrhoea were the largest contributors to the zymotic death-rate. Of scarlet fever 1163 cases were notified, this being a larger number than in any year since 1887. Of the 1163 cases, 780 or 67 per cent. were isolated in hospital. Of typhoid fever 157 cases were notified, a number which has remained fairly constant for some years past. But it is clear that notification is utilised to get rid of the conditions with which this disease is commonly associated, and hence diminution may ultimately be expected. The fatal attacks of this disease during the year were under the average. Perhaps one of the most interesting parts of the report is a description of a hospital for small-pox, in which all outgoing air passes through a furnace. Dr. Barry, of the Local Government Board, has visited the institution, and has made experiments as to the germ-destroying properties which it is said to ensure. An official report on this inquiry may be expected, and we trust that it will not be delayed since the matter is one of great importance to sanitary authorities generally. There is much in Dr. Evans's report that we must pass over. But we cannot conclude without saying that in style, matter, and utility it is an excellent document.

#### VITAL STATISTICS.

##### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6005 births and 3680 deaths were registered during the week ending Dec. 3rd. The annual rate of mortality in these towns, which had been 18·6 and 18·9 per 1000 in the preceding two weeks, declined again to 18·8 last week. In London the rate was 17·7 per 1000, while it averaged 19·6 in the thirty-two provincial towns. The lowest rates in these towns were 10·3 in Birkenhead, 13·0 in Halifax, 14·0 in Huddersfield and 15·2 in Bradford; the highest rates were 25·1 in Brighton, 25·7 in Salford, 27·5 in Hull and 28·7 in Bolton. The 3680 deaths included 429 which were referred to the principal zymotic diseases, against 392 and 424 in the preceding two weeks; of these, 150 resulted from measles, 70 from scarlet fever, 60 from diphtheria, 56 from whooping-cough, 45 from "fever" (principally enteric), 44 from diarrhoea and 4 from small-pox. No fatal case of any of these diseases occurred last week in Wolverhampton or in Derby; in the other towns they caused the lowest death-rates in Oldham, Huddersfield and Halifax, and the highest rates in Manchester, Bolton, Brighton and Salford. The greatest mortality from measles occurred in Manchester, Cardiff, Bolton, Croydon, Salford, Hull and Brighton; from scarlet fever in Salford, Cardiff, Sunderland, Bolton and Plymouth; from whooping-cough in Norwich, Manchester, Salford, Birmingham and Bolton; from "fever" in Swansea; and from diarrhoea in Plymouth and Burnley. The 60 deaths from diphtheria included 39 in London, 6 in Manchester, 2 in West Ham, 2 in Salford and 2 in Sheffield. Two fatal cases of small-pox were registered in London, one in Liverpool and one in Sheffield, but not one in any other of the thirty-three large towns; 19 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and one in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3882, against 4063, 4045 and 3945 on the preceding three Saturdays; 302 new cases were admitted during the week, against 404 and 303 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 340 and 353 in the preceding two weeks, declined again to 343 last week, and were 92 below the corrected average. The causes of 67, or 1·8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth,

Bristol, Bolton, Oldham, Sunderland, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Liverpool, Salford, and Huddersfield.

##### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the preceding three weeks from 20·6 to 23·7 per 1000, further rose to 24·2 during the week ending Dec. 3rd, and exceeded by 5·4 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·3 in Paisley and 17·1 in Dundee to 27·7 in Aberdeen and in Edinburgh, and 58·7 in Leith. The 673 deaths in these towns included 112 which were referred to measles, 16 to scarlet fever, 12 to whooping-cough, 9 to diarrhoea, 7 to "fever," 2 to diphtheria, and not one to small-pox. In all, 158 deaths resulted from these principal zymotic diseases, against 127 and 162 in the preceding two weeks. These 158 deaths were equal to an annual rate of 5·7 per 1000, which exceeded by 3·5 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had increased from 61 to 104 in the preceding three weeks, further rose to 112 last week, of which 39 occurred in Leith, 36 in Edinburgh, 18 in Aberdeen, and 16 in Glasgow. The deaths referred to scarlet fever, which had risen from 13 to 28 in the preceding four weeks, declined again last week to 16, and included 6 in Glasgow, 3 in Leith, and 3 in Greenock. The 12 fatal cases of whooping-cough showed a further increase upon recent weekly numbers, and included 11 in Glasgow. The deaths referred to different forms of "fever," which had been 11 and 4 in the preceding two weeks, rose again to 7 last week, of which 3 occurred in Leith and 2 in Dundee. The deaths from diseases of the respiratory organs, which had been 137 and 141 in the preceding two weeks, declined to 134 last week, and was 197 below the number in the corresponding week of last year, when influenza was prevalent. The causes of 86, or nearly 13 per cent., of the deaths in the eight towns last week were not certified.

##### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·9 and 22·8 per 1000 in the preceding two weeks, rose again to 23·3 during the week ending Dec. 3rd. During the past nine weeks of the current quarter the death-rate in the city averaged 23·1 per 1000, the rate for the same period being 17·8 in London and 22·6 in Edinburgh. The 156 deaths in Dublin during the week under notice exceeded by 3 the number in the preceding week, and included 6 which were referred to "fever," 2 to diarrhoea, one to scarlet fever, and not one either to small-pox, measles, diphtheria, or whooping-cough. In all, 9 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 1·7 in London and 7·9 in Edinburgh. The deaths referred to different forms of "fever," which had been 2 and 4 in the preceding two weeks, further rose to 6 last week. The 2 fatal cases of diarrhoea corresponded with the number in the preceding week. The death from scarlet fever was the first fatal case of this disease recorded during the past four weeks. The 156 deaths registered in Dublin last week included 44 of infants under one year of age and 33 of persons aged upwards of sixty years; the deaths of infants considerably exceeded those recorded in any recent week, while those of elderly persons showed a marked decline. Four inquest cases and 4 deaths from violence were registered; and 45, or more than a fourth, of the deaths occurred in public institutions. The causes of 30, or nearly 25 per cent., of the deaths in the city last week were not certified.

#### THE SERVICES.

##### MOVEMENTS OF MEDICAL STAFF.

SURGEON-COLONEL CHURCHILL has arrived from India and assumed Administrative Charge of Woolwich. Brigade-Surgeon-Lieutenant-Colonel Evatt has been posted to Woolwich for duty. Brigade-Surgeon-Lieutenant-Colonel McWalters and Surgeon-Captain Miles have arrived from India in the *Malabar* on completion of their tour of service. Surgeon-Lieutenant-Colonel Gabbett has taken over Charge

of the Women and Children's Hospital at Colchester. Surgeon-Captains Reilly and McDowell have embarked in the *Euphrates* for service in India. Surgeon-Captain O'Brien has been transferred to Armagh and Surgeon-Major Smythe to Cahir.

#### ARMY MEDICAL STAFF.

Surgeon-Lieutenant-Colonel Poole Robert Gabbett, from the Seconded List, to be Surgeon-Lieutenant-Colonel (dated Nov. 28th, 1892).

#### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Chas. Elliott Leopold Barton Hudson, Middlesex Yeomanry (Duke of Cambridge's Hussars), to be Surgeon-Lieutenant (dated Dec. 7th, 1892).

#### INDIAN MEDICAL SERVICE.

The undermentioned Medical Officers of the Indian Medical Service have been posted to General duty, Poona district:—Surgeon-Lieutenants F. E. Swinton, S. H. Burnett, and T. Jackson. The following appointments have been made:—23rd (2nd Battalion Rifle Regiment) Bombay Infantry, Surgeon-Lieutenant W. C. Sprague, to officiate in Medical Charge, vice Surgeon-Captain Wm. Jennings, transferred to the Civil Department for temporary employment. The services of Surgeon-Captain C. H. L. Palk, I.M.S., have been placed temporarily at the disposal of the Government of India. The services of Surgeon-Colonel J. Richardson, M.B., Officiating Surgeon-General and Sanitary Commissioner with the Government of India, have been placed at the disposal of the Government of the New Provinces and Oudh. Surgeon-Colonel J. G. Pilcher, Officiating Inspector-General of Civil Hospitals, North-West Provinces and Oudh, has been appointed to officiate as Inspector of Civil Hospitals, Bengal. The services of Surgeon-Captain W. Vost, M.B., I.M.S., Bengal, have been placed at the disposal of the P. W. Department, and the services of Surgeon-Captain P. W. O'Gorman, I.M.S., Bengal, have been placed temporarily at the disposal of the Government of Bengal. The services of temporary Uncovenanted Medical Officer H. A. McLeod have been placed at the disposal of the Chief Commissioner of Assam. The following appointments of the Army Medical Staff are announced:—Brigade-Surgeon-Lieutenant-Colonel R. P. Ferguson, Army Medical Staff, has been appointed to the Administrative Medical Staff of the Bengal Command, to be Principal Medical Officer, Allahabad District, vice Surgeon-Colonel F. W. Wade, transferred to the Home Establishment. Surgeon-Colonel C. H. Y. Godwin, having been appointed to the Administrative Medical Staff of the Bengal Command, to be Principal Medical Officer, Rawalpindi District, vice Surgeon-Colonel A. Allan, deceased. Brigade-Surgeon-Lieutenant-Colonel F. B. Scott, M.D., C.M.G., having been appointed—in anticipation of promotion—to the Administrative Medical Staff of the Bengal Command, to be Principal Medical Officer, Quetta District, vice Surgeon-Colonel W. Graves, transferred. Under instructions from the Horse Guards, Surgeon-Colonel F. W. Wade, Brigade-Surgeon-Lieutenant-Colonel A. F. Churchill, M.B., and Surgeon-Captain T. Rudd, M.D., have been directed to proceed to England in anticipation of promotion.

#### NAVAL MEDICAL SERVICE.

The following appointments have been made:—Fleet Surgeons: W. Graham to the Pembroke Dockyard and J. L. Sweetnam to the *Inflectible*; Staff Surgeons Horace X. Browne to the *Phabe* and Thomas M. Sibbald to the *Catypso*; Surgeon H. W. G. Green to the *Bellerophon*.

#### THE VOLUNTEER OFFICERS' DECORATION.

This decoration has been further conferred upon the undermentioned officers:—*Western District*: 1st Devonshire (Western Division, Royal Artillery), Surgeon-Lieutenant-Colonel John Steele Perkins and Veterinary Lieutenant James Heath; 1st Glamorganshire, Surgeon-Lieutenant-Colonel Charles Pegge; 1st Gloucestershire, Surgeon-Lieutenant-Colonel Francis P. Lansdowne; 2nd (Prince of Wales's) Volunteer Battalion, the Devonshire Regiment, Surgeon-Major (ranking as Lieutenant-Colonel) John Henry S. May, retired; 4th Volunteer Battalion, the Devonshire Regiment, Surgeon-Lieutenant-Colonel Joseph Harper; 2nd Volunteer Battalion, the Prince Albert's (Somersetshire Light Infantry), Surgeon-Lieutenant-Colonel Edward Liddon, M.D.; 3rd Volunteer Battalion, Surgeon-Lieutenant-Colonel Wm. Harford Glover Phelps, M.D., and Surgeon and Honorary Surgeon-Major Henry William Livett, retired; 1st (Brecknockshire) Volunteer Battalion, the South Wales Borderers, Surgeon and Honorary Surgeon-Major

Jas. Williams, retired; 1st (City of Bristol) Volunteer Battalion, the Gloucester Regiment, Surgeon-Major (ranking as Lieutenant-Colonel) George M. Stansfeld, retired; 1st Volunteer Battalion, the Duke of Cornwall's Light Infantry, Surgeon-Captain (Honorary Surgeon-Major) Richard Charles Mason Pooley; 1st (Pembrokeshire) Volunteer Battalion, the Welsh Regiment, Surgeon-Major George Griffith and Surgeon-Lieutenant-Colonel Edward P. Phillips, retired; 3rd Glamorgan, Lieutenant-Colonel James Griffith Hall.—*Home District*: 2nd Middlesex, Surgeon-Lieutenant-Colonel John Wickham Barnes and Surgeon-Lieutenant-Colonel Thos. Thyne, M.D. 3rd Middlesex, Surgeon-Major John Cook, M.D.—*Royal Engineers*: 1st London, Surgeon-Lieutenant Richd. Buswell; 1st Middlesex, Surgeon-Lieutenant-Colonel Matthew Baines, M.D.; 1st Surrey (South London), Surgeon-Captain Charles Swaby Smith; 2nd Volunteer Battalion, the Oxfordshire Light Infantry, Surgeon and Honorary Surgeon-Major Edwd. Law Hussey, retired; 1st Bucks, Brigade Surgeon-Lieutenant-Colonel William James Shone; 1st Volunteer Battalion, Princess Charlotte of Wales's (Royal Berkshire Regiment), Surgeon and Honorary Surgeon-Major James Ellison, M.D., retired; 2nd Volunteer Battalion, the Duke of Cambridge's Own (Middlesex Regiment), Surgeon and Honorary Surgeon-Major John Prince, retired; 1st Middlesex (Victoria and St. George's), Surgeon and Surgeon-Major (ranking as Lieutenant-Colonel) William Geo. Shepherd, M.D., retired; 4th Middlesex, Brigade-Surgeon-Lieutenant-Colonel Andw. Clark; 12th Middlesex (Civil Service), Surgeon and Honorary Surgeon-Major Henry Spencer Smith, retired; 13th Middlesex (Queen's Westminster), Surgeon and Honorary Surgeon-Major Robert Cross, retired; 3rd London, Surgeon and Honorary Surgeon-Major Charles Hy. Bennett, M.D., retired; 14th Middlesex (Inns of Court), Surgeon and Honorary Surgeon-Major Alfred Cooper, retired; 15th Middlesex (the Customs and Docks), Surgeon-Lieutenant-Colonel Frederick William Humphreys, Surgeon-Lieutenant-Colonel Robert Gordon Tatham and Surgeon-Major (ranking as Lieutenant-Colonel) Walter Dickson, M.D., retired; 19th Middlesex (St. Giles's and St. George's, Bloomsbury), Surgeon-Lieutenant-Colonel Henry Reynolds Myers and Acting Surgeon William Gill, retired.—*Volunteer Medical Staff Corps* (London Companies): Surgeon-Lieutenant-Colonel Commandant Arthur Treherm Norton, Surgeon-Lieutenant-Colonel William Henry Platt and Surgeon-Captain (Honorary Surgeon-Major) John Adam Watson.

#### RETIREMENTS IN THE MEDICAL STAFF.

There has not been a very active run of promotion of late in the army medical staff, and it is perfectly natural that any measures likely to retard it should be unpopular and that the Army List ought to be often scanned, especially towards the close of the year, to see what the prospects are in this respect. In the ensuing year there will be five retirements on account of age in the administrative ranks of the medical staff.

#### SOLDIERS AND TOBACCO.

Sir Evelyn Wood says, in a recent report on the Aldershot manoeuvres, that there was less smoking in the ranks on the line of march than in the previous year, with the resulting advantage that fewer men fell out. He appears to be in favour of regulating the quality as well as the quantity of tobacco smoked by the soldier. By far the larger number of soldiers in all armies smoke. During the Franco-German war one of the first things the German soldiers sought was tobacco. The loss of his pipe is keenly felt as a real deprivation by the military and civilian smoker alike, and there is no gift more valued by the inmate of a work-house or a lunatic asylum than tobacco. Without entering into the *pros* and *cons* of the tobacco controversy it cannot be doubted that the immoderate use of the strong kind of tobacco which soldiers affect is often very injurious to them, especially to very young soldiers. It renders them nervous and shaky, gives rise to palpitation, and is a factor in the production of the irritable or so-called "trotting heart," and tends to impair the appetite and digestion. It would be a great point gained if soldiers could be induced to smoke some of the milder kinds of tobacco, and we do not see why these should not be sold in canteens. The soldier unfortunately prefers the strongest, because it is cheaper, inasmuch as a small quantity produces an effect that would only result from the consumption of a much larger quantity of any of the milder kinds. On active service it would be a good plan for the Government to supply the soldier with tobacco of the latter sort either as a free issue or at a trifling charge.

## THE SOLDIERS' MESSING.

We are very glad to hear that means have been taken for spreading a practical knowledge of the new method of military cooking among the regiments and depôts quartered at various stations by sending the superintendent of the Army School of Cooking at Aldershot to inspect their cook-houses and appliances and to afford practical instruction in the Aldershot system, which is said to have given such general satisfaction at that camp.

## SICKNESS AMONG THE TROOPS IN NORTHERN INDIA.

We have already alluded to the prevalence of sickness among the troops at Peshawar and to the removal of one regiment, the Royal Welsh Fusiliers, to Nowshera, about twenty-eight miles distant. Cherat, the nearest hill station to Peshawar, is also occupied by half a regiment from that garrison. At this season and during the autumn months Peshawar is frequently—we may say usually—unhealthy from the prevalence of a bad form of malarious fever. Removal from the Peshawar valley is often the only reliable remedy; quinine and other drugs are of little or no avail as long as the affected men remain in the district. The Northumberland Fusiliers relieves the Royal Welsh Fusiliers at Peshawar, and the Royal Scots Fusiliers will be railed from that station to join the camp of exercise at Rawal Pindi.

## ROYAL VICTORIA HOSPITAL, NETLEY.

Lord Sandhurst, Under Secretary of State for War, accompanied by his private secretary, visited the Royal Victoria Hospital last week, and went over the buildings and grounds with the principal medical officer of the district.

## THE WOUNDS CAUSED BY SMALL-BORE BULLETS.

Our service contemporary, the *Army and Navy Gazette* of last week, published a communication from Veterinary-Captain Smith, the late professor of the Army Veterinary School, detailing the results of further experiments with the Lee-Metford bullet on the bones of the horse at ranges fixed at every hundred yards—from 100 to 1000 yards. These results are apparently mainly determined by differences in the strength and resistant powers of the substance and structural arrangement of the bone at the part struck. From 50 to 200 yards the effect is pulverising and destructive; but from 300 to 1000 yards the effect is different, according to the part of the bone hit—that is to say, whether it be the dense resistant substance of the shaft or the cancellous spongy structure of the ends of the bone. In the former case, the shaft of the bone is shattered and fissured in all directions with much loss of substance, and it makes but little difference as regards the destructive effect whether the bullet be fired at 50 or 1000 yards. In the latter case, the bullet may only give rise to a hole in the spongy cancellous structure of the extremities of the bone struck, which is sometimes perfectly clean, but frequently fissured, the fissures extending or not into the joint. If the extremity of the bone, as in the case of some of the bones of the extremities of a horse, consists more of compact than spongy structure, then the pulverising effect is produced and no clean hole is made.

## THE REMOVAL OF ST. GEORGE'S BARRACKS.

According to a contemporary St. George's Barracks, Trafalgar-square, are to disappear, and the Guards from these barracks are to have new quarters built for them at Millbank. We presume that the building now appropriated for recruiting purposes at St. George's Barracks and approached from the back of the square, will also disappear, and it is quite time that it did so, for the very inferior accommodation afforded for recruiting is not by any means of a creditable character. It seems to us that smart, airy and clean-looking rooms or offices, of a more attractive kind than the old buildings, are required for this purpose, and they should be in prominent positions and not hidden away in a sort of cul-de-sac or at the end of a back street.

## ROYAL MILITARY COLLEGE EXAMINATION.

The candidates for the competitive examination for Sandhurst have been exceptionally numerous on this occasion and gave full occupation to the medical officers responsible for their preliminary physical examination. The candidates are stated to have numbered about 800 altogether, and as the cadetships to be competed for only amount to about 120, the competition will be severe.

## PRACTICAL HINTS FOR LADY TRAVELLERS TO INDIA.

We have received copy of a small pamphlet published by

Mr. Stanford of Cockspur-street, on "How to Pack, How to Dress, and How to Keep Well on a Winter Tour in India." Its author is the Hon. Mrs. Neville Lyttleton, and it sets forth various details in these directions which are likely to prove useful to ladies embarking for India. Its price is one shilling, and if the information contains nothing particularly new, it is of a ready practical kind and supplies hints and suggestions in regard to various points that might otherwise fail to be remembered.

## Correspondence.

"Audi alteram partem."

## "ABDOMINAL SECTION IN CERTAIN CASES OF PELVIC PERITONITIS."

To the Editors of THE LANCET.

SIRS,—Although present at the adjourned discussion at the Obstetrical Society on Dr. Cullingworth's paper I was not prepared then to express an opinion on the many issues raised, but trust that the importance of the matters in dispute may be a sufficient excuse for trespassing on your valuable space in the form of a letter. Personally I think the title of the paper was unfortunate, grouping as it did several classes of pelvic disease, which, whether diagnosed before or after operation, ought to have been classified under their distinctive headings. Had Dr. Cullingworth instead confined his paper to the frequent connexion which exists between inflammatory disease of the uterine appendages and pelvic peritonitis, giving at the same time his views as to the value of abdominal section in those cases alone, a less discursive but much more valuable discussion would have been the result. At the present moment the treatment of the above class of diseases may with fairness be called the burning question of the day in gynecological circles; and the reduction to plain well-defined lines of their therapeutics would be conferring a real benefit upon the profession at large. Some of the speakers seemed to look upon appendageal disease as a comparatively trifling malady, and one which usually occasional rest, assisted by nature, would cure.

No doubt a large number of these cases do get well under non-operative treatment, but not such as those described in Dr. Cullingworth's paper, where the evidences of disease were unmistakable and the lives of the patients imperilled by the recurrent attacks of pelvic peritonitis. It is the so-styled conservative treatment of such cases which is directly responsible for incomplete operations and great mortality. Anyone who has had much experience of this kind of operative work must have been compelled at times to stay his hand by reason of the extent and intimacy of visceral adhesions; and yet, in the face of this, which is common experience, we are asked to believe that abdominal section is indicated rarely only as a *dernier ressort*. That these neglected cases kill is indisputable, although frequently the death certificate is differently worded. They are fertile producers of intestinal obstruction, of septicæmia and general peritonitis, and, short of these, are responsible for more invalidism in women than probably any other form of disease. Much in the course of the debate was made of Dr. Cullingworth's mortality, and Dr. Williams went so far as to say that the death-rate of the series—viz., 18 per cent.—was not higher than that throughout the country in this class of case, with a few exceptions. If so, it would be deterrent, but it is far from the truth, as was abundantly proved by Dr. Cullingworth himself when speaking of his latest cases and others. Out of my last fifty cases I have lost two patients; although in no case has an operation been done without a clear history of recurrent inflammation, objective signs of appendageal disease and, unless in cases urgently demanding operative relief, treatment for a sufficient period by rest. This seems to me the truly conservative treatment and that which is in accordance with the teachings of modern surgery, and Dr. Cullingworth is to be congratulated in having the courage to express so unequivocally his opinions.

I am, Sirs, yours faithfully,

Nottingham, Nov. 6th, 1892.

GEORGE ELDER, M.D. Glas.

## "DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—Having had the advantage of being a pupil of the late Sir James Syme in the Edinburgh Royal Infirmary, and having administered chloroform to some of his operation cases, I may perhaps be allowed to sound a forgotten or neglected note in the admirable rules for chloroformisation which he always laid down, and to which I have always strictly adhered, without ever meeting with a fatal though sometimes with an alarming case in thirty years' practice. The particular detail in the mode of administration to which I refer, and on which Sir James Syme was very emphatic, is that it should never be given on lint, and especially on folded lint. Now, it is a significant fact that amongst recent cases reported in THE LANCET of "deaths under chloroform," in at least two of them the chloroform was administered on folded lint. No further comment is needed.

I am, Sirs, your obedient servant,

WM. ROBINSON HILL, M.D. Edin.

Lymington, Hants, Dec. 5th, 1892.

To the Editors of THE LANCET.

SIRS,—Under the above heading in THE LANCET of Dec. 3rd you publish two letters, the second of which expresses Dr. Van Someren's classification of deaths under the use of chloroform. Curiously enough, the first letter by Dr. Rowland supplies details of a fatal case, showing that the accompanying circumstances were such as Dr. Van Someren advocates; the open method was adopted, and the heart was to all appearance healthy. From Dr. Rowland's account I conclude that death was due to one of two causes: either the reflexes were not abolished, and thus, although the patient was doubtless insensitive to pain, yet the effect of the skin incision was to arrest the heart through reflex irritation of the pneumogastric, the heart's action being already probably embarrassed by the upward pressure of the ascitic fluid; or the patient actually received a poisonous dose of the drug, and its lethal effect on the medulla resulted. That deaths occur with painful regularity under chloroform is apparent, notwithstanding recently expressed opinions of its perfect safety if the respiration solely be attended to. Every anaesthetist is aware that there are certain cases in which it is impossible to administer ether with due regard to the safety of the patient; but that there are numberless instances of chloroformisation in which ether, an undoubtedly generally safer anaesthetic, might have been used is equally true. With the present method of giving gas to start with ether is robbed of many of its defects; and I am of opinion that the annual death roll from anaesthetics would be materially diminished were ether, instead of chloroform, more frequently made use of.

I remain, Sirs, yours obediently,

Old Burlington-street, Dec. 2nd, 1892. PERCY EDGELOW.

## "DEATH AFTER VACCINATION."

To the Editors of THE LANCET.

SIRS,—*Appropos* of an annotation which appeared in THE LANCET of last week under the above title, will you allow me space to make a few comments? If the beneficent results of vaccination are to be obtained with the fewest mishaps, surely some further steps should be taken by the authorities to render such lamentable accidents as far as may be impossible. It is important to recognise that, however admirably vaccination may be performed in respect to selection of the lymph and technique of the operation, in a certain proportion of cases in the first eight days or so more or less unusually severe local inflammatory effects will occur, and "rashes" evolve—e.g., various phases of erythema multiforme and urticaria. Such complications, however, are usually manageable, transient and benign, and of no great importance, though naturally distasteful or alarming to the parents. It is after the vaccination has been pronounced successful and the child dismissed, no doubt with admirable advice and instructions for protecting and healing the sores, that real danger is to be apprehended from various infections. There is a certain proportion of mothers to whom it is nearly or quite useless to give instructions. The only safe course to prevent the occasional disastrous ill effects is to keep the children under observation until the sores have healed up under the

influence of proper treatment. Surely it is contrary to all modern teaching that children should be allowed to go about for weeks and even months with open sores, exposed to all sorts of possibilities of infection. A very simple trouble, and one which most commonly brings discredit on vaccination, is the auto-inoculation of pus producing the affection known as impetigo contagiosa. Formerly, I believe, it was the custom to see the vaccinated children later than the eighth day, and I strongly advocate that the vaccination should not be considered completed until the sores have satisfactorily healed.—I am, Sirs, yours faithfully,

T. COLCOTT FOX, M.B. Lond.

Harley-street, W., Dec. 6th, 1892.

## "THYMOL AS AN ANTHELMINTIC REMEDY."

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to confirm the general results of Dr. Sonsino in his communication under the above heading in THE LANCET of Nov. 19th, 1892? For about two years I have used thymol as the one efficient remedy for expelling anchylostoma from more than two hundred patients. Unlike other vermifuges it seems to have a special action upon this worm, but I have always found that it was necessary to administer the drug two, three or more times. My usual habit is to give it once a week until upon two occasions no worms have been found in the stools after its administration. During the intervals the patient is dosed with iron to try to counteract his great anaemia. I originally gave ninety grains of thymol in six wafers within six hours, but I have now reduced the amount to sixty grains in two doses, accompanied by brandy. Even with this modified quantity anemic patients are seriously collapsed for about four hours, the temperature falls about two degrees Fahrenheit, and the pulse and respirations become correspondingly less frequent. I only mention this to show that thymol must not be given in large doses without great care. Like Dr. Sonsino, I find that any coexisting ascarides or oxyurides are brought away by thymol, though not more satisfactorily than by the usual santonine and enemata. So far thymol has not yielded good results on the few taenia mediocanellata patients on whom I have tried it. It seems irrational to suppose that it could have any beneficial action on blood worms, such as filaria hominis. I have tried it, however, on several chronic cases of distoma haematobium, without any effect. To these I gave it in doses of four grains three times a day for several weeks.

I am, Sirs, yours faithfully,

Cairo, Nov. 26th, 1892.

F. M. SANDWICH, M.D.

## "COMPOUND FRACTURE OF THE INFERIOR MAXILLA TREATED BY WIRE SUTURE."

To the Editors of THE LANCET.

SIRS,—In justice to the late Mr. Hugh Owen Thomas of Liverpool, perhaps you will allow me to draw attention to the fact that about twenty years ago, in your columns, he described his method of treating compound fracture of the inferior maxilla by wire suture. In your last week's issue Mr. Carter of Leeds describes, as if original, a procedure almost identical even to detail with that of Mr. Thomas. The Thomas method has been described in some of the standard Surgeries, and two editions of the *brochure* descriptive of the operation have been published, the last by Mr. H. K. Lewis in 1881. I have performed the little operation in quite a large number of cases, and the ingenious way in which Mr. Thomas has shown us how to twist the ends of the wire may save Mr. Carter, as it has saved me, from the necessity of the guttapercha splint.

I am, Sirs, yours faithfully,

Liverpool, Dec. 6th, 1892.

ROBERT JONES.

## THE CONDITION OF THE COMPETITORS' FEET AFTER THE LONG DISTANCE MARCH.

To the Editors of THE LANCET.

SIRS,—As considerable interest has very naturally been taken in the great marching competition held at Kingston in November I shall be glad if you will allow me to present to

your readers a few facts which have come under my own personal observation with reference to the condition of the men's feet after the march. By the courtesy of the officers on duty at the barracks I was allowed to see all the competitors who were present at the time when I arrived. Unfortunately I was unable to reach Kingston on Sunday, Nov. 6th, before the afternoon and by that time most of the competitors who had completed the distance had left. I wish to express my best thanks for the permission to see the cases which was so readily granted.

The greatest sufferer in his feet, mainly from ill-fitting boots, was a sergeant of volunteers. His feet were red, swollen, painful and blistered. The largest blister was situated between the ball of the great toe and the arch of the foot. It corresponded exactly in position with, and was obviously caused by, the projecting edge of the lining of the sole of the boot. The lining leather was altogether too hard. When the finger was pushed against the projecting edge the "upper," which was saturated and softened owing to the dirty state of the roads, receded and left the finger resting upon this sharp chisel-shaped unyielding ridge; so sharp was this, that it caused pain in the finger-tip when the latter was pressed firmly upon or drawn along it. There was also a blister on the little toe just on the classical position for a corn, due mainly to the fact that the boot had been built on a badly-shaped last. On the back of the heels were sores, and rather deep ones, due to friction against the seam which corresponded in position to the top of the stiffening. The shape of the heel of the boot was moreover such as to allow too much up and down movement of the foot with each step.

It was an agreeable surprise to go from this bad case and find the line men, who came in second in the competition, without exception in a far better condition. After an examination of each foot of each man in the team there was really little on the whole worth noting. One man—and he only on one foot, the right—had a blood blister the size of a shilling on the inner and upper aspect of the ball of the great toe. This was caused most probably by friction against the end of a deep and stiff wrinkle which ran across the boot. Two men had tender callosities in the soles of their feet. A few of the men had little blisters at the tips of some of their smaller toes. One complained of aching ankles and a pain in the arch of his foot, due chiefly, no doubt, to the fact that he suffered in a slight degree from flat foot. Some of the men showed no traces of suffering in their feet.

It is not my intention now to criticise in detail the regulation boot which this team wore, but merely to mention a few decidedly good points which it possesses, and which give it superiority over the commoner boots in the market, and especially over the bad pair which the volunteer referred to wore. 1. The general form of the sole is good, being true to the normal outline of the foot, not kidney-shaped, as so many inferior boots are made nowadays, owing to the employment of badly shaped lasts. 2. The lining is soft, smooth, and remarkably free from anything like a projecting seam. 3. The method of lacing is one of the best. 4. The shape of the heel of the upper part of the boot, made as it is to the natural form of the heel of the foot, is one of the best features. The cut of this heel is peculiar, and peculiarly good, one would imagine, as it must greatly prevent up-and-down friction, which is such a fruitful cause of ulcers and lesser troubles at the back of the heel.

It would be going beyond my present purpose to refer to other points which would more properly form part of a treatise on boots in general. My reason for desiring to see the competitors' feet and boots after a severe test such as this notable march was that I had made boots a hobby. At one time I suffered rather severely myself from corns brought on by London boots and pavements, and I soon realised how much larger a proportion of the public suffered in the same way than I had previously supposed to be the case. Considering the severity of the pain often endured, notwithstanding high prices paid for boots by some of the best makers, it seemed to me that this subject deserved very careful study, and would require a long series of experiments before anything like a satisfactory solution of the difficulty could be arrived at. The relief of corns is a comparatively simple matter, but their complete prevention is a problem not yet solved. As the result of many experiments, I have had boots made for myself by which corns can be produced or prevented in my own case at will. In the earlier attempts, as might have been anticipated, there were many difficulties and discouragements encountered. I shall be very glad to show the boots to any member of the medical profession who

may be suffering from either corns or a tendency to flat-foot and wish to try an experiment; and I hope to have an early opportunity of showing them at one of our medical meetings.

I am, Sirs, yours faithfully,

London, Dec. 5th, 1892. ALFRED EDDOWES.

### "TREATMENT OF OPHTHALMIA AMONGST CHILDREN OF 'THE POOR.'"

To the Editors of THE LANCET.

SIRS,—Your annotation on this subject affords me an opportunity of entering a protest against the fashionable system of boxing up a crowd of cachectic children in a special isolation hospital to cure them of infectious ophthalmia. "It is impossible," you say, "to confine them for many weeks consecutively to the infirmary, and the managers naturally hesitate to incur the expense of a special medical attendant and a staff of nurses, and the still greater expense of building &c. .... When the treatment has been continued for a year or more the disease is practically abolished." Let us hope so. Infectious granular ophthalmia is, *par excellence*, the eye disease of Ireland. If it were the practice of Irish ophthalmologists to incarcerate hundreds of such cases in special isolation hospitals and to keep them there for "a year or more" under subjection to all the paraphernalia of green shades, darkened windows, compress bandages &c., thousands would not number the cases of blindness, or tens of thousands of pounds the cost of isolation hospitals. Let me advise English school managers and my brother ophthalmologists to try our method—to spend not one penny in the shutting up of a crowd of poor cachectic children in hospital, but to make arrangements to give them a run in the fields for a couple of months, combined with a little local treatment to the conjunctiva, a liberal farinaceous dietary and a suitable tonic treatment. If they will adopt this course I can promise them a cure—in the average case—not within "a year or more," but within a month and at a nominal cost. I subscribe to the theory of isolation as a protection against infection, but am of opinion that, in this disease at least, that hobby is being ridden to death.

I am, Sirs, yours truly,

ARCHIBALD HAMILTON JACOB, F.R.C.S.I.  
Dublin, Dec. 8th, 1892.

### "MEDICAL AID ASSOCIATIONS."

To the Editors of THE LANCET.

SIRS,—In view of the inquiry by a committee of the General Medical Council into the proceedings of Medical Aid Associations, may I appeal to all medical men who have had experience of these bodies either in the capacity of medical officer, locum tenens, or otherwise to communicate with me? The experience of former medical officers will be particularly valuable as being less liable to be biased by personal interests than that of present incumbents, and there seems no means of communicating with such except by this public appeal.

I am, Sirs, yours faithfully,

Birmingham, Dec. 8th, 1892. LESLIE PHILLIPS.

### "PERIODATES IN CHOLERA."

To the Editors of THE LANCET.

SIRS,—There is a paragraph in your "annotations" under this head (p. 1230) which is not in accordance with chemical and physiological laws, which I therefore desire to correct. The misstatement is that the action of the periodates "can only depend on the readiness with which they give up free iodine." Permit me to explain that, although many hundreds of observations have been made of the action of the periodates upon the living body in health and in disease, in no single instance has an examination of the body's fluids or any one of its various excretions ever yielded "free iodine."

I am, Sirs, yours faithfully,

London, Dec. 7th, 1892. RICHARD WEAVER, F.C.S.

SUCCESSFUL VACCINATION.—Mr. Frank L. C. Richardson, public vaccinator for the Rhayader district of the Rhayader Union, Radnorshire, has received a Government grant for successful vaccination for the second time in succession.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

*Workhouse Extension at Stockport.*

THE Local Government Board, through their inspector, have for some time been urging the Stockport guardians to build a new workhouse in supplement of the accommodation existing at their present establishment at Shaw Heath. At their last meeting the guardians had under consideration the Board's recommendation, but they decided to reject it and to extend their present workhouse instead, and thus to provide for present needs. The guardians appear to be labouring under the pleasant delusion that the pauper class are steadily becoming more temperate and that destitution is therefore certain to decrease—at any rate, in the Stockport Union. They therefore are about to inform the Local Government Board that in their opinion any considerable extension of workhouse accommodation is at the present juncture unnecessary.

*Small-pox Prevalence.*

Since my last letter fresh cases of small-pox have been reported in many of the towns hereabouts, in which it had been prevalent more or less for some weeks previously. At Warrington, Liverpool, Oldham, St. Helens, and also in this city itself, fresh cases have occurred from time to time; whilst a sharp outbreak has recently taken place at Lymm, a residential suburb of Manchester. Infection appears to have been imported in the first instance from Warrington, and the disease has since spread somewhat rapidly. Altogether about twenty-four cases have been reported up to the present date, and, as the village of Lymm is but a small one, considerable anxiety amongst the inhabitants has been the not unnatural result. According to the local papers the Lymm local authority are doing their best to erect a hospital for the accommodation of the small-pox patients who are now being nursed at home; but hitherto their efforts have been unsuccessful.

*Salford Royal Hospital: an Experiment.*

The annual meeting of the Board of Governors of this excellent charity was held on Nov. 24th, at the Royal Hospital in Chapel-street. The report stated that the abolition of the recommended system had been agreed upon by the governors, and that for the period of the ensuing twelve months, at any rate, they had decided to try the experiment of admitting to the benefits of the charity all persons, not in receipt of Poor-law relief, who were too poor to be able to afford to pay for medical attendance and medicine. During the past year the experiment of allowing some of the members of the nursing staff to attend private patients at their own homes had been tried with encouraging success, and in several instances applications had been refused in consequence of the limited number of nurses available for this purpose. Altogether the hospital and the dispensary which is attached to it appear to be in a flourishing condition, and it is certain that both departments of this excellent institution are doing an admirable and much-needed work in the County Borough of Salford.

*The Ladies' Health Society and their Work.*

From a recent report it appears that the female visitors who act under the joint direction of the Ladies' Health Society and the medical officer of health are still doing useful work in the slums of our city. In the course of last quarter the female health visitors, thirteen in number, paid nearly seven thousand sanitary visits to poor people and, in addition, made 650 special inquiries on behalf of the medical officer of health into cases of infectious disease or of death. According to the returns just issued the work of the health visitors appears to have increased enormously during the recent quarter as compared with previous ones. It is, however, explained in the report that this increase is actual only in part, and to a certain extent results from the adoption of a new system of bookkeeping in the Public Health Office, by which every sanitary visit is placed to the credit of the appropriate health visitor. In the pamphlet from which this information is taken there is a table which shows the amount of work done in the several districts of the city, and accompanying the table is a chart showing the relative position of the several districts and indicating by appropriate shading the areas which still require the attention of the Society. In addition to the work of the Ladies' Health Society here referred to there is another association which appears

to be working on similar lines, and which will eventually do good work in Manchester. This association is termed "The Ladies' Society for Visiting the Jewish Poor." It has been established for several years and has been usefully but quite unostentatiously employed amongst the Jewish residents of Red Bank, one of the worst and most neglected districts of the city. The female district visitor employed by the Jewish Society, in common with the health visitors of the before-mentioned Society, works under the supervision of the medical officer of health, and we learn that this excellent organisation will shortly provide a second district visitor for the benefit of the Jewish poor in the populous neighbourhood of Strangeways, which is almost exclusively occupied by members of that community and where the conditions of life sadly require the attention of the Society.

*Owens College.*

At the last meeting of the Council Mr. Thomas Jones, M.B. Lond., F.R.C.S. Eng., surgeon to the Manchester Royal Infirmary, was appointed to the Professorship of Surgery about to become vacant by the resignation of Professor A. W. Hare. At the same meeting the Council established a Professorship of Clinical Surgery in the College, and appointed to this professorship Mr. Walter Whitehead, F.R.C.S. Edin., F.R.S., surgeon to the Manchester Royal Infirmary. Both these appointments are subject to the approval of the court of governors.

December 6th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*South-west Lancashire Assizes.*

MR. JUSTICE GRANTHAM is presiding in the Crown Court at the Assizes, which opened on the 5th inst. The calendar is a heavy one, containing the names of nearly 120 cases. Among those of medical interest was that of William Henry Hale, described in the calendar as a physician, but the genuine character of whose American diploma is even doubtful; while it is an undoubted fact that he possesses no British qualifications to entitle him to practise in the United Kingdom. He was charged with obtaining money by false pretences from a number of persons who consulted him for deafness. He was to-day convicted and sentenced to eighteen months' hard labour. There is also the case of the man Duckworth, charged with the murder of a little girl at Blackburn. There is another charge of murder against a woman, she having left her child on a doorstep, taken its clothes away and so caused its death. Four men are charged with the manslaughter of a boy who dared them to throw him into the canal. They, taking him at his word, threw him in, and, though they did all they could to rescue him, he sank at once and was drowned. There are many other very serious offences.

*Advertising Quacks.*

The utter futility of the recent Act for the suppression of advertising quacks is shown by what has occurred in this city. Posters and handbills of a suggestive and even indecent character are industriously distributed, but they are so carefully worded as not to constitute a breach of the law. Unholy alliances between duly qualified and registered medical practitioners and these obscene quacks continue to exist, and it is greatly to be hoped that some means may be found of bringing them before the Medical Council. At the same time the public must take their full share of the blame for the continual existence of these gentry. There is a positive demand for quackery and an impatience with the rational bounds and etiquette of legitimate medical practice.

*A Year's Apprehensions for Drunkenness.*

The Head Constable's report gives a total of 10,088 persons (5613 males, 4475 females) as having been drunk when apprehended. Of these, 5404 were drunk and disorderly, 2998 drunk and incapable, 510 assaulting police constables, 184 other assaults and 992 other offences. Three-fifths of the whole number were natives of Liverpool, Ireland furnished 1609, Scotland 324, Wales 175, the Isle of Man 20 and foreign countries 265. These figures are eloquently in favour of foreigners, a large number of whom are employed in various capacities on board ships and steamers, and whose chief recommendation is their sobriety.

*A Year's Accidents.*

Another table of melancholy interest in the Head Constable's annual report is that of the number of accidents happening within the city and reported by the police. Of a total of 2127 there were 124 fatal cases. Running over by carts, cars &c. caused 400, injuries on board vessels in docks 334, falling into docks, canals &c., 404. Only 65 were caused by burning and 8 by firearms.

December 8th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

*Tynemouth Infirmary.*

THE annual meeting of the Tynemouth Victoria Jubilee Infirmary has been held. During the year there had been 118 in-patients, being an increase of twenty over the previous year. The financial statement was satisfactory, showing a balance in hand on the year's work. Alderman R. M. Tate, J.P., retired because, he said, he did not believe in a perpetual chairman.

*Westmoreland and Cumberland.*

The twenty-third annual report of the Westmoreland and Cumberland Hospital Sunday Fund has been issued, which shows that the total sum collected and remitted to the fund during the present year was £962, against £893 in the previous year. Of the £912 distributed by the committee the Cumberland Infirmary (Carlisle) got £493; Carlisle Dispensary, £47; Carlisle Fever Hospital, £121; Silloth Convalescent Institution, £111; and Workington Infirmary, £140.

*Cumberland Infirmary Nursing Scheme.*

The Cumberland Infirmary nursing scheme is now said to be fairly launched. The contracts for the building have been let for about £2000 and the amount of money in hand reaches £2500. More it is confidently expected will be provided by the public. The existing nursing staff will be removed into the new buildings as soon as they are ready, and it is hoped to add twenty more nurses, who will be for the most part employed in nursing the sick in various parts of the city of Carlisle.

*The late Dr. M. W. Taylor.*

The *Carlisle Journal* has a long appreciative notice of the late Dr. M. W. Taylor, who died at Earl's Court, London, last week. He was long in active practice in Penrith, Cumberland, where he played a conspicuous part in the formation and maintenance of the Cumberland and Westmoreland Archaeological Society, and to him is said to belong the credit of having been the first to point out the dangerous properties of milk as a means of transmitting scarlet fever. He also wrote a valuable paper on the Fungoid Origin of Diphtheria.

*The Outbreak of Small-pox in the Northallerton Union.*

On Wednesday, Nov. 30th, at the adjourned meeting of the Northallerton Rural Sanitary Authority, cases of small-pox were reported in the district, one of which proved fatal yesterday. The medical officer has urged the necessity of revaccination in all cases. So far as could be ascertained the disease had been brought into the district by cattle drovers or tramps. Owing to the spread of the disease in various parts of the country the Darlington Board of Guardians have rescinded a resolution adopted two years ago, not to prosecute parents for omitting to have their children vaccinated.

*The New Asylum at Sunderland.*

The Sunderland Town Council having applied to the Local Government Board for sanction to borrow over £20,000 for the purchase of a site for a new lunatic asylum at Ryhope and other objects, and improvements in the town, instructions have been given for Colonel Charles Henry Luard, R.E., to hold an inquiry at the Town Hall on Dec. 8th at 11 A.M.

*The Bowes Museum at Barnard Castle.*

There is a financial hitch in the carrying on of this very fine museum, and the trustees have applied to the Charity Commissioners for more means to keep up the museum and park. The commissioners have named £1000 as the maximum to be allowed for one year, and suggest local subscriptions and a charge for admission. The trustees reply that they have no power to charge for admission. The difficulty is, however, only temporary, as it is said that a substantial portion of the

legacy of the late Mr. John Bowes of £100,000 will soon be available.

*Scheme for Sick Nursing at Seaham Harbour.*

A large town's meeting has been held at Seaham Harbour to consider and promote a scheme for sick nursing which has been proposed by the Marchioness of Londonderry, who opened the proceedings. A committee was appointed to consider the matter in all its bearings, and also the question of the future use of the infirmary.

Newcastle-upon-Tyne, Dec. 7th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS)

*Public Health Affairs in Leith.*

OWING to the prevalence of scarlet fever and measles in Leith the attendance at the board schools has fallen off by a third, or even a half, in some of the schools. The School Board met to consider the question of attendance, and decided to close the schools if they obtained a certificate from the medical officer of health. By obtaining such a certificate it is understood that the education grant for the schools is obtained notwithstanding that they are closed. After this a special meeting of the Public Health Committee was held, and the application of the School Board considered, when it was decided that they would not take the responsibility of closing the schools, nor, as it appears, were they prepared to acknowledge that there was an epidemic in the burgh. Leith has not adopted the system of notification which has been so productive of benefit to the adjoining community of Edinburgh—in fact, the public health authorities seem to appreciate very imperfectly their important responsibilities to the community. There has been trouble about hospital accommodation for infectious diseases, there was much dissatisfaction at the time cholera was rife in Hamburg as to the precautions at Leith against its admission into this country, and now there is this epidemic of scarlet fever and measles, not to mention typhus fever and a death-rate of somewhere about 58 per 1000. It can hardly therefore be wondered at that there is a feeling of dissatisfaction and want of confidence in the actions of those responsible for the care of the public health.

*Edinburgh Hospital for Women and Children.*

The annual meeting of the subscribers to this hospital was held last week, Dr. Sibbold presiding. At the dispensary there had been 225 patients on the books, and the total visits to it were 1537. In the cottage hospital attached to it thirty-nine patients had been received in the course of the year, sixty-nine visits had been paid by the resident medical officer and sixty-six by students. The balance-sheet showed a deficiency of about £31, the total expenditure for the year being a little over £279.

*Royal Society of Edinburgh.*

The first ordinary meeting of this Society was held on Monday, Professor Sir Douglas MacLagan, M.D., in the chair. The chairman thanked the Fellows for doing him the honour of again electing him as their president and then proceeded to deliver a short introductory address. In it he referred to the meeting of the British Association which had been held in Edinburgh since they last met and to the important part which Scotsmen and Fellows of the Royal Society had taken in the establishing and working of the Association.

*The Medical Preliminary Examination.*

The Joint Board of Examiners, created by Ordinance No. 13 of the Universities Commissioners, met in Edinburgh for the first time in the end of last week. The representatives from Aberdeen, St. Andrews and Glasgow were present as well as those representing Edinburgh. The Board resolved:—  
1. Beginning with the examinations in 1893 the papers set for the Arts and Medical Preliminary Examinations shall be the same. 2. In judging the English paper the examiners shall fix a higher and a lower standard, the lower being sufficient for candidates in the Medical Preliminary Examination. 3. Every candidate for the Medical Preliminary Examination must pass on the higher standard in at least one of the required subjects, and may pass on the lower standard in the remaining subjects where there is a lower standard. 4. The standard for French and German in the Medical Preliminary Examination shall be that prescribed in the Arts Ordinance,

No. 11. 5. For the first Medical Preliminary Examination, to be held under this Board in the spring of 1893, no candidate shall be required to pass on the higher standard in any subject. 6. The ensuing spring Preliminary Examinations for Arts, Science and Medicine shall begin on Saturday, April 1st next. 7. For the Preliminary Examinations in April next each University shall accept the equivalents already announced in the calendar of that University.

#### *The Waste of Water in Edinburgh.*

The Works Committee of the Edinburgh and District Water Trust are taking further steps to check the waste of water in the city and district. Two large meters are to be placed on one of the main pipes. The engineers have been instructed to report on the construction of a pressure reducing tank to check waste during the night; they have also been instructed to bring up a monthly report of the night inspections and investigations for the prevention of waste.

#### *Health of Edinburgh.*

At the meeting of the Public Health Committee held on Dec. 6th the report was submitted on the health of the city for November. The total number of deaths was 495, making the death-rate 22.43 per 1000, as compared with 25.97 for the corresponding month of last year and 14.42 for November, 1890. The average death-rate for the month during the past five years was 18.04 per 1000. The death-rate in the three main divisions of the city was, in the New Town 17.38 per 1000, in the Old Town 31.56 per 1000 and in the Southern Division 13.08 per 1000. Of the deaths, 47.88 per cent. were of children under five years. Diseases of the chest caused 26.46 per cent. of the deaths and zymotic diseases 30.30 per cent. Of the zymotic diseases, 1 was from typhoid fever, 7 from diphtheria, 12 from scarlet fever, 126 from measles, and 3 from erysipelas. The birth-rate was 26.87 per 1000. The intimations of infectious diseases during the month numbered 2350; of these, 1 was typhus fever, 21 typhoid fever, 26 diphtheria, 1 small-pox, 244 scarlet fever, and 2057 measles.

#### *Health of Aberdeen.*

For last week the returns of zymotic cases were: Measles, 359; scarlet fever, 19; diphtheria, 4; erysipelas, 2; puerperal fever, 1; total cases, 385; being a decrease of 85 as compared with the previous week. The decrease is due to the decline of the measles epidemic.

#### *Aberdeen University Senatus.*

At a meeting of the Senatus of Aberdeen University held last Saturday it was reported that the Milne Medical Bursary had been conferred on Mr. Robert G. Henderson, M.A.; the Duthie Medical Scholarship on Mr. W. E. G. Duthie, M.A.; and the Gregor Medical Bursary on Mr. Andrew Thomson. Professor Matthew Hay was re-elected an assessor from the Senatus to the University Court. It was intimated that Mr. J. Scott Riddell, M.A., C.M., M.B., had been appointed assistant to the professor of surgery; Mr. Alex. Brown, M.A., B.Sc., to the professor of natural history; and Mr. John Marnoch, M.A., M.B., C.M., to the professor of institutes of medicine.

#### *Public Health of Glasgow.*

In the fortnight ending Nov. 26th, the death-rate was 22.3. There were four deaths from small-pox—a male, aged thirty-seven, vaccinated; a female, aged twenty-eight, vaccinated; a male, aged twenty-one, "hæmorrhagic," unvaccinated; a male, aged four weeks, "hæmorrhagic," unvaccinated. This number had not been equalled since the spring of 1884. Small-pox, however, is diminishing. Three weeks ago there were fifteen fresh cases, two weeks ago nine fresh cases, last week seven fresh cases. The authorities thus seem to be mastering the outbreak. Scarlet fever is decreasing, but measles is rapidly increasing.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Outbreak of Fever at the Hibernian Military School, Phoenix Park.*

SIR C. CAMERON, M.D., in his report to the Board of Works as to the outbreak of sickness among the boys in the Hibernian school, states that the fever is of a non-enteric character, of short duration, and probably in origin dietetic. As stated recently in these columns the health of the boys has been exceedingly good, the mean annual death-rate per 1000

during the last three decades having been 6.5, 4.5, and 3.75 respectively, and there has not been a single death from any of the principal zymotic diseases for the past ten years. Some months since the Board of Works made arrangements to apply the "oxygen process" to the school outfall in the coming year, while the supply of sterilisers used on the irrigation field has been increased. The cause of the outbreak will, however, be investigated by a committee, of whom Sir George Porter, Bart., will be chairman, when the dietary of the boys, the water-supply and other matters will be dealt with. It is rumoured that the water-supply of the school is insufficient, and that water has to be stored in tanks for the use of the inmates.

#### *Transactions of the Royal Academy of Medicine, Vol. X.*

In addition to the papers noticed in this column last week I may allude to some others in the sections of Surgery and Pathology. "Ballooning of the Rectum" is the title of a communication by Mr. Hamilton. Attention was drawn to this condition in THE LANCET of 1889 by Mr. Bryant, but Mr. Hamilton described the symptom in 1883. He has seen this condition under the most varied and dissimilar circumstances, but cannot fix its value as applied to the purpose of diagnosis or prognosis of disease of the intestine higher up. There are three papers on cerebral surgery: one of a case of traumatic epilepsy, aphasia and paralysis of six years' duration, treated by trephining, and in which recovery took place, by Mr. Heuston; trephining for cerebral cyst by Mr. Wheeler, and for uncomplicated word blindness by the same operator, in the last case with success; and trephining for meningitis, by Mr. McArdle. In the Section of Pathology Mr. Patteson describes two cases of adenoma of the breast observed in two children, aged thirteen and twelve years and nine months respectively; and Dr. E. H. Bennett has an excellent paper on the Rarer Forms of Fracture of the Carpal Extremity of the Radius, and gives some examples illustrating more particularly fracture of the radial-styloid and longitudinal fracture or fissure of the lower end of the bone. Dr. James Little has a short account of a case of painless cancer of the liver, the organ weighing 178 ounces; and Dr. A. W. Baker contributes a report on the Present Aspect of Dental Caries. Space will not admit of further references; but the present volume is not less valuable than its predecessors.

#### *County Weasford Infirmary.*

Mr. Gibbon, one of the governors, is plaintiff in an action against the management of the infirmary with a view to restraining the defendants from applying the interest on £1000—money left to the infirmary—towards increasing the salary of Mr. Hadden, the surgeon of the institution. The facts are as follows:—Mr. Hadden was elected about four years since, the advertisement of the vacancy stating that the salary would be £120 yearly, with residence; but it could only be, as a matter of fact, £94 per annum, the sum presented under the statute by the grand jury. It was chiefly in consequence of this that the governors devoted the interest of the £1000 bequest towards increasing the surgeon's salary. Whichever way the matter may be decided, the interests of the infirmary must necessarily suffer.

#### *Health of Ireland: September Quarter.*

The births registered during the quarter amounted to 25,340 and the deaths to 17,167, or 14.8 per 1000. The birth-rate was 0.5 under the average for the corresponding quarter of the past ten years, and the death-rate was 0.2 over the rate. There was a marked subsidence of the epidemic of measles in Dublin and Belfast. Scarlet fever proved very fatal in Castlereagh Union, and whooping-cough was prevalent in some unions in Connaught, but the general mortality from these diseases was below the average. Compared with the corresponding quarter of 1891, the returns of pauperism show a decrease of 279 in the average number of workhouse inmates on Saturdays during the quarter, and a decrease of 3384, or 5.5 per cent., in the average number of persons on out-door relief. The fever (typhoid) at present prevailing in Cork is of a mild type, and consequently the mortality is very low.

#### *Entries at the Belfast Medical School.*

During the present winter season 164 students are attending the Royal Hospital, being only three less than last year. At the Queen's College there are 220 in the medical faculty, being between thirty and forty students less than in 1891-92. This falling off is in the number of the first-year men

principally, but it must be recollected that last year's entries (to avoid the fifth year) were phenomenally large.

#### The Samaritan Hospital.

A meeting of the committee of this hospital was held on Dec. 6th for the purpose of appointing two honorary attending physicians, when Dr. Campbell (Demonstrator of Anatomy at Queen's College, Belfast) and Dr. St. Clair Boyd (Surgeon to the Western Hospital for Women and Children) were elected.

#### The Belfast Medical Students' Association.

A deputation from the above association, consisting of the secretary and ex-secretary, presented a memorial to the Belfast Board of Guardians on Tuesday last. It appears that in 1891, at the request of the Students' Association, the board granted the privilege to the students of entering the wards of the union infirmary for the purpose of receiving clinical instruction, of which the students availed themselves, but that, on the ground that the teaching staff was not sufficiently large, the Senate of the Royal University refused to accept the certificates of the medical officers. The memorial referred to the difficulty students had in gaining experience in certain diseases which would be obviated were they able to attend the infirmary, and they beg, as now an election is about to take place owing to two medical resignations, that the board of guardians will increase the number of their medical officers. The chairman said that what the students wanted was to have the staff increased and the infirmary thrown open in the same way as the Royal Hospital. If they had power to do this they would be most happy to meet their views, but he was afraid that it would be objected to, as they could not increase the staff without expense. One of the deputation said this could be met by the students' fees. Ultimately it was agreed that a subcommittee of the board should meet the Medical Students' Association and the President of Queen's College, Professor Redfern, and Professor Cuming, on Tuesday, Dec. 13th, to consider the subject.

The Cork Dispensary Committee have elected Mr. Callaghan medical officer in the room of Dr. Townsend, resigned.

December 6th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### Medical Students v. Town Councillors: Termination of the Dispute.

A FORTNIGHT ago I communicated the particulars of the conflict that had arisen between the dressers of the Hôpital St. Antoine and the section of the Municipal Council charged with the superintendence of the Paris hospitals. The matter was so warmly taken up by the entire mass of students that the competitive examinations for admission to "dresserdom" had to be deferred *sine die*, and the expediency of a general strike of dressers was even mooted. Fortunately, more moderate counsels have prevailed, and the reproach of having abandoned poor, innocent sufferers to their own resources has been spared the *jeunesse médicale* of this Faculty. The quarrel has ended, as most quarrels should—viz., in a compromise. Acting in accordance with a formal wish expressed by the Société Médicale des Hôpitaux and the Conseil de Surveillance de l'Assistance Publique, the director of the latter department and the Municipal Council have consented to let bygones be bygones, and the offending *externe*, M. Salmon, has accordingly been reinstated. Henceforth all such misunderstandings will be dealt with by a Commission of the Conseil de Surveillance mentioned above. The *examens d'internal et d'external* have been resumed as usual, and the sensitive and fiery Gaul, both municipal and medical, will, it is hoped, now that *l'honneur est satisfait*, "pursue the even tenour of his way."

### Approaching Removal of the Académie de Médecine.

The ordinary tourist, however well acquainted he may be with noteworthy buildings in Paris, would assuredly be puzzled to specify the situation of the dingy structure within whose portals the learned members of the Académie de Médecine periodically foregather. The reason is not far to seek. The building is quite unworthy of the society it shelters, its aspect being forbidding and mean, and the Rue des Saints-Pères exceedingly narrow at that point. Many attempts have been made by the Academy to secure more fitting quarters,

and I am happy to be able to announce that a move will be made at no distant date to the Rue Bonaparte, where, in exchange for a piece of land belonging to the Academy and 263,500 francs, the Municipal Council have, on behalf of the Assistance Publique, agreed to cede a building hitherto occupied by a branch of the Mont-de-Piété or pawnbroking office.

### A Sensible Measure.

The careful observer cannot fail to notice the ravages made amongst the working classes of Paris by the habitual abuse of such beverages as absinthe, vermouth, amer Picon, eau de mélisse, vulnéraire &c. During a visit I paid to Dr. Lancereaux's wards at the Hôtel Dieu, on Monday last, I saw two well-marked instances of paralysis of the extensors in women addicted for years to the excessive consumption of vermouth and eau de mélisse respectively. In the latter case the forearms as well as the legs were affected. In one man under Dr. Lancereaux's care the abuse of these liquors had so exaggerated the reflexes, that a slight tickling of the soles of the feet made him bound violently out of bed. Dr. Lancereaux, who has for many years paid special attention to alcoholism in all its forms, is never tired of agitating for the repeal of the taxes on such comparatively innocent beverages as beer, cider and perry. These he distinguishes from their noxious congeners by the name of *boissons hygiéniques*. He contends, and rightly contends, in my opinion, that the cheapening of these drinks would contribute powerfully to the diminution of alcoholism. This view appears to have gained some adherents in the Chamber of Deputies, for Parliament is now considering a proposal to abolish all duty on wine, beer, cider, perry and hydromel. No beer worth drinking can be procured here for less than threepence a glass, which, with at least a penny for the waiter, brings the cost up to double what it is in England. In the *cafés* on the boulevards a glass costs forty or fifty centimes. It is to be hoped that the Chamber will, if it adopts the proposed measure, supplement it by increasing the duty on beverages, the consumption of which, freely adulterated as they are, constitutes a danger to the community. I am persuaded that this would sensibly diminish the mortality from phthisis in this city. About 10,000 victims succumb annually to this scourge in Paris.

### Æsthetic Disinfection.

The gratuitous disinfection of clothing and bedding provided by the municipality is happily becoming more and more *à la mode* in Paris; but side by side with the public ovens there have sprung up private ones whose claims to patronage, as set forth in elaborate circulars, consists in the fact that the yellowing of the linen which occurs at the municipal establishments is by their process counteracted by further treatment. The Conseil d'Hygiène will soon take the question into consideration and it is intended to have the operations of these enterprising *industriels* carefully superintended by the medical inspectors attached to the Prefecture of Police. A code of regulations will also be issued, so as to render private disinfection a reality.

December 7th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### Cholera in Russian Poland.

YESTERDAY'S official report of the state of cholera in Russian Poland gave the numbers of cases and deaths in the various Governmental districts as follows: Radow 28 and 12, Siedlec 32 and 18, Lubin 8 and 6, Warsaw 4 and 7, Lomza 2 and 3, in three days.

### Remuneration of Medical Students who served in the Hamburg Epidemic.

During the recent cholera epidemic in Hamburg a misunderstanding arose as to the remuneration of the medical students who volunteered their services. The dean of the medical faculty here has now published the following: "The Cholera Commission of the Senate of Hamburg, in a letter addressed to the undersigned dean, expresses its thanks to all the students of medicine who assisted in combating the cholera epidemic, and at the same time intimates the wish to send the undermentioned fee to all those who worked in the Hamburg hospitals in the belief that their services were to be remunerated at the rate of 20 marks a day."

*The Charité.*

In the fiscal year 1889-90 the number of patients treated in the Berlin Charité was 21,457, in 1890-91 only 20,352. This decrease is attributed to the opening of the hospital in Urban. On the other hand, the number of women who have been delivered in the Charité has been almost constantly increasing since 1876. In that year it was 879 and in 1889-90 it was 1564.

*The Berlin Hospitals.*

At a meeting of the Central Committee of the Berlin Medical District Associations on the 25th ult., it was resolved to express to the municipal authorities of Berlin the wish that greater opportunity should be afforded by the municipal hospitals for the practical training of medical men, and that the medical service in the said hospitals may be so organised that there may be one physician and two assistant-physicians for every 100 or 120 patients.

*Myxœdema.*

The first trial made in Germany of the treatment of myxœdema by implanting the thyroid gland of an animal, or injecting the juice extracted from such glands, has been recently made by Professor Mendel, of Berlin, who reports a slight improvement in the condition of the patients.

*The Hofmann House.*

The Hofmann House, called after the late Professor Hofmann, which is to serve as the home of the German Chemical Society, is estimated to cost 1,200,000 marks. The Langenbeck House cost only 300,000 marks.

*"An Indian Oculist."*

An "Indian oculist" was expelled from Munich by the police last Thursday.  
December 4th.

## EGYPT.

(FROM OUR OWN CORRESPONDENT.)

*Visit of the Khedive.*

HIS HIGHNESS THE KHEDIVÉ, accompanied by his Greek physician and other members of his staff, paid an official visit to the School of Medicine on Nov. 24th and was much pleased with the signs of recent progress which were shown to him. The pathological museum has now been seriously taken in hand and has lately been enriched by a valuable collection of calculi, old instruments and surgical specimens gathered together by Duruy Bey, the professor of surgery. This medical school was started in 1837 by French enterprise, revived again temporarily under distinguished Germans, such as Griesinger, Bilharz and Pruner, and now is being successfully galvanised into life by English energy.

*Mecca Pilgrimage.*

The annual pilgrimage to Mecca passed off without any question of cholera being raised, and some 18,000 returning pilgrims passed through the observation encampment at Tor during July and August in very fair health. It is true that thirty-nine of them, mostly Turks, Persians and Tunisians, died in camp, but the quarantine statistics show that twenty-nine of these deaths occurred in old men between the reputed ages of sixty and ninety-five. The most common causes of death were general debility and chronic enteritis. The entire absence of cholera at Mecca in 1892, in spite of its presence there in the two preceding summers, is interesting when compared with the alternative march of cholera along the north of Europe. It would appear that cholera is never endemic in Mecca in spite of the utter neglect of sanitation, but requires always to be imported by pilgrims from India or Persia.

*The Nile Flood.*

The supply of water in the river during the summer months of this year was exceedingly low, and, as often happens, this was followed by a dangerous rise. It was not until September that anxiety was felt about the safety of the Nile banks; but for two months incessant vigilance had to be displayed. The chief danger was in the lateness of the flood and in the fact that the maximum rise was kept up for twenty-one days instead of for one day, as in 1887, when the last high Nile took place. To the credit of English engineers it ought to be noted that the floods of 1887 and 1892 are the only great floods on record in the history of Egypt when no breach of the banks has taken place and no disaster has occurred.

There are, roughly speaking, some 7000 millions of cubic metres of water stored in the irrigation basins of Upper Egypt in a high flood year, and this water has to be discharged again into the river, late enough to prevent any flooding in Lower Egypt, but early enough to ensure time for the crops to be sown and ripened before the hot weather can dry them up. If the basins are emptied at the slowest possible rate it means that 11,000,000 cubic metres of water are added every hour to the already overcharged river. In 1887 about 39,000 acres of crops were destroyed by the flood, and this damage is hardly worth mentioning in comparison to the disasters of 1878, when whole villages and miles of railway were swept away. In 1892 only 7700 acres of crops—mostly maize—have been destroyed. In order to successfully manage this year's flood a special credit of £12,000 was voted and spent chiefly on stone, sacks, timber, trees and rope &c. For the last month the river has been sinking rapidly and all danger is long over.

*Malarial Fevers.*

Dengue has not appeared this autumn, though it did so in an epidemic form after the high flood of 1887. Intermitting fever, usually rare and seldom before seen in Europeans without previous malarial taint, has occurred several times this autumn in consequence of the high Nile. The victims can be traced to dwelling-houses the floors of which are below the height of maximum river rise, as in many of the oldest parts of the town. The plasmodia of malaria have for the first time in Egypt been discovered in the blood of some of these patients by Dr. Kauffmann. Treatment with methylene blue has been tried in the cases of some natives, but it does not appear to be in any way superior to quinine for uncomplicated malaria, as occasionally seen in this country.

*Tænia Nana.*

Twenty worms of the tænia nana variety were recently found in the small intestine of a negro, who was admitted moribund into the native hospital. This is only the second time the worm has been found in Egypt since Bilharz first discovered it here in 1851.

*Port Said Hospitals.*

Dr. Robertson, after being eight years in charge of the native hospital at Port Said, has lately succumbed to a severe attack of neglected dysentery. His death, which is universally regretted by all who know him, is the first which has taken place among English doctors since they were admitted to the Government service in 1884. He has been succeeded by Mr. Frank Milton. The hospital has 100 beds and is nursed by seven French sisters of charity, and, besides gratis patients, admits those who pay at rates varying from four to eight francs a day. Many of the poorer patients are admitted from Turkish vessels, suffering from chronic dysentery and malaria. The second hospital at Port Said is an English one, due to the energy of Lady Strangford shortly before her death. The staff consists of an English doctor, three English nurses and a probationer. There are thirty-five beds, all for paying patients, and there has recently been added an infectious ward capable of holding eight beds.

November 23th.

## Obituary.

M. W. TAYLOR, M.D. EDIN., F.S.A.

THE announcement of the death of Dr. Taylor, which took place on the 24th ult., will be received with regret by all who had the privilege of his friendship. He was born in 1824 at Portobello, near Edinburgh, and was educated in that city and at Portsmouth. Having obtained his degree, which by special permission of the Senatus he gained at the age of twenty, he acted as class assistant to Professor A. J. Balfour, and distinguished himself by the proficiency he attained in botanical studies, in recognition of which he was elected a Fellow of the Botanical Society of Edinburgh. Towards the end of 1844 Dr. Taylor proceeded to Paris, and there studied under the most eminent surgeons of that city. Thereafter he visited various foreign capitals, and thus extended his knowledge of the methods pursued by physicians and surgeons abroad. In 1845 he repaired to Penrith, and, having acted for a few months as *locum tenens* to Dr. John Taylor, he subsequently succeeded to the practice on the

death of that gentleman. In 1858 he married Miss M. W. Rayner, daughter of a Liverpool merchant; and for nearly forty years carried on with great success his professional work in the above-mentioned city. As evidence of the esteem in which he was held by his fellow townsmen and in recognition of the value of his services, both public and professional, he was presented, on his retirement from practice, with a handsome service of plate. Dr. Taylor's contributions to medical literature were neither few nor unimportant. His investigations into the part played by milk in the dissemination of scarlet fever excited considerable interest at a time when that article of domestic consumption had been previously unsuspected as a source of infection. The fungoid origin of diphtheria also engaged his attention, and in a paper contributed to a local medical society fresh light was thrown on that important matter. Dr. Taylor, however, did not confine his interest to medical and pathological topics, but extended his sympathies to other subjects connected with the mental and physical well-being of his neighbours. He was the founder of the Penrith Literary and Scientific Society, and the formation of the free library, reading-room and museum was largely due to his exertions. Altogether the citizens of Penrith have reason to congratulate themselves that for so many years they numbered the deceased physician amongst them. The funeral, which took place on the 28th ult. in the grounds of Christchurch, was attended by all the more prominent residents of the town, many of the friends of the deceased coming from a distance to show their respect to his memory.

#### ALFONSO CORRADI.

THOSE of us who learned to admire and esteem Professor Corradi at the last International Congress of Hygiene and Demography and who looked forward to renewing our acquaintance with him at the International Congress of Medicine and Surgery in September next will hear with great regret that he died at Pavia on the 28th ult. in his sixtieth year.

Alfonso Corradi was a native of Bologna, where he was born on the 6th of March, 1833. He passed through a brilliant curriculum in general and professional education at the Local University, where he graduated with the highest honours in medicine and surgery in the years 1855 and 1856. He was yet a young man when he filled the post of assistant-surgeon at the Ospedale di Vita, after which, in 1859, he gained in public competition, over several very formidable rivals, the coveted professorship of general pathology in the University of Modena. In 1863, again by open competition, he was appointed to the chair of general pathology at Palermo, where he taught with great success till 1867, when he was transferred to Pavia as lecturer on general therapeutics, materia medica and experimental pharmacology—a post which he held till last year, at the close of which he was called by the unanimous vote of the medical faculty of the University of Bologna to the chair of the history of medicine in that seat of learning.

His powers as a clinical physician and private consultant were only second to his ability as an expositor, whether by tongue or by pen, from the professorial chair or at the editorial desk. As early as 1857 he started, in conjunction with Professor Brugnoli, the *Rivista Medica*, which soon rose to be the first of its class in Italy; but ephemeral work was far from exhausting his energies. Within eight years from that date he had published the first volume of his monumental treatise, entitled "Gli Annali delle Epidemie in Italia dalle prime Memorie sino al 1850" (Annals of the Epidemics in Italy from the Earliest Records to 1850), a treatise which ran to five octavo volumes, and was succeeded by another of more exclusively modern interest, "La Chirurgia in Italia dagli Ultimi Anni del Secolo fino al Presente" (Surgery in Italy from the Closing Years of Last Century to the Present Time), Bologna, 1871. Similar historical works are his "L'Ostetricia in Italia dalla Metà del Secolo fino al Presente" (Obstetrics in Italy from the Middle of the Present Century till the Year now Passing), in three quarto volumes, Bologna, 1872; his edition, with preface and copious annotations, of the "Lettere del Lancisi al Morgagni e parecchie altre ora per la prima volta pubblicate" (Letters from Lancisi to Morgagni and several others now for the first time published), Pavia, 1876; and his "Memorie per la Storia della Università di Pavia e degli Uomini più illustri che v' insegnarono" (Memoirs in Illustration of the

History of the University of Pavia and of the most distinguished Men who taught there), Pavia, 1874-8, 3 vols., 4to. It will be remembered also that in 1888, on the solemn celebration of the eighth centenary of the "Mother of Universities," Bologna, Professor Corradi's pen was once more in requisition, when he delighted the *savants* assembled there from all parts of the world with his graphic sketch of the origin, the development and the future outlook of his *alma mater*. Other works of his it would be impossible to give in full detail; but mention may be made of his French paper contributed to the *Union Médicale* of Paris, 1865; "Sur l'Étiologie et l'Histoire de la Pèlagre"; to his "Escursioni d'un Medico nel 'Decamerone'" (A Physician's Excursions into Boccaccio's "Decameron"), 1878; and to other lucubrations, only possible to a physician who was also a widely read man of letters, published in successive volumes of the "Atti dell' Istituto Lombardo." Professor Corradi's high qualities of head and heart were known and appreciated in every great medical school. In Germany and in Great Britain he was held in especial admiration and esteem, and his compatriots have noted with something like national pride the unique honours conferred on Italian medicine in the doctorates bestowed on him by the Universities of Cambridge and London.

#### LUIGI AMABILE.

"UNA vera perdita per la scienza" (a real loss to science) is the compendious note of our Italian contemporaries on the death of the Senator Luigi Amabile, Professor of Pathology in the University of Naples. A student and graduate in that school, he soon became connected with its teaching staff, first in the department of surgery and then in that of pathology: He was a bold and successful operator when laparotomy was yet in its infancy, while his treatise written in conjunction with Tommaso Virnicchi, and published at Naples in 1859, "Sulle Soluzioni di Continuo del Intestino e sul Loco Governo" (On Solutions of Continuity in the Intestines and in their Prevalent Seat), did much to promote sound and effective abdominal surgery. Besides his professorial duties, discharged with much energy and acceptance, he was an unwearied author and critic of papers read and discussed before the various medico-chirurgical societies of Naples and its provinces. His published memoirs and pamphlets on subjects of scientific and professional interest are very numerous, and several of these procured him the honorary fellowship of learned bodies, not only in Italy, but beyond the Alps. He represented more than once in the Italian Chamber the constituency of Avellino in the Liberal interest and was, in consideration of his statesmanlike intervention in hygienic and educational legislation, promoted to a seat in the Senate. To the last he retained his connexion with his *alma mater*, in which he held the post of Professore Ordinario e Direttore di Materia Patologica with equal usefulness and credit. Over and above his strictly professional work he distinguished himself in historical research, and, apart from his writings in medicine and surgery, established for himself an honourable reputation for his treatises on the philosopher and humanist Tommaso Campanella and on the "Inquisizione di Napoli." He died on the 24th ult.

#### THOMAS WATTS, M.R.C.S., L.S.A.

MR. THOMAS WATTS, who died on Nov. 29th, was for many years in practice in the country around Frampton-on-Severn, where he lived until he was compelled to retire on account of heart disease. Born in 1822, he received his preliminary education from Dr. Hales of Bath, entering King's College, London, in 1840. After leaving the College he worked with his father, on whose death in 1860 he succeeded to the practice.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the College, held on Thursday, the 8th inst., Mr. Bryant, the President, in the chair, the minutes of the ordinary Council meeting of Nov. 10th were read and confirmed.

The Council confirmed their resolution of the 10th ult.,

and removed a Member from the privileges &c. of Membership, and the Secretary is to request him to return his diploma.

On the recommendation of the Nomination Committee, Mr. Clement Lucas was appointed an Examiner in Anatomy for the second examination for the Membership. Mr. F. Treves was appointed a member of the Court of Examiners in Surgery.

It was also agreed that, as recommended by the Nomination Committee, in pursuance of a unanimous resolution of the Board of Examiners in Anatomy and Physiology for the Fellowship, the papers on anatomy and physiology be in future given on separate days instead of on the morning and afternoon of the same day as at present arranged.

Sir W. MacCormac was elected a member of the Court of Examiners in Dental Surgery in succession to Mr. Heath.

The best thanks of the Council were given to Mr. Heath for the delivery of the Bradshaw Lecture on "Diseases of the Nose."

The President stated that he had accepted, on behalf of the Council, a silver box which had once belonged to Edward Jenner, presented to the College by Mr. A. M. Sydney Turner, J.P., M.R.C.S., of Gloucester, and the best thanks of the Council were given to Mr. Turner for his present.

Mr. Heath was appointed a member of the Committee of Management, in the place of Mr. Hutchinson.

A letter was read from the President reporting the proceedings of the General Medical Council at their late session, and the best thanks of the Council were given to him for his services as the representative of the College.

It was agreed that the lectures during the coming year (1893) should be delivered at 5 P.M. instead of 4 P.M. as hitherto.

## Medical News.

**ACCIDENT TO A SURGEON AT LEEDS.**—Mr. Corrie of Nippet Cottage, Burmantofts, on Tuesday last, was conveyed to the Leeds Infirmary with a simple fracture of one of his legs consequent on a fall upon some ice-covered steps.

**THE annual meeting of the Manchester Hospital Sunday and Saturday Fund** was held on Monday. There had been received for the former £4305 17s. 6d., against £4852 0s. 11d. in 1891, showing a decrease of £544 3s. 5d. The amount contributed to the Hospital Saturday Fund was £3924 5s. 8d., against £3960 2s. 11d. last year, or a decrease of £35 19s. 3d.

**RUGBY SCHOOL RUNS.**—We understand that new regulations have been made respecting these runs, which it is stated are for exercise and not for competition. There will be two sets of "runs," one for big and another for small boys, any boy being able to obtain a medical certificate releasing him from these exercises if physically unfit. A responsible person will be in charge of the runs, and all those taking part in them will keep together until within two miles of the house.

**SCARBOROUGH FEVER HOSPITAL.**—At the instigation of the urban sanitary authority of Scarborough the erection of a temporary fever hospital has been commenced within a third of a mile from the Royal Artillery Barracks. The rural sanitary authority have protested against the erection of this building, their medical officer having stated that infection could make itself felt for over 1000 yards. At a meeting of the rural authority on Dec. 1st it was unanimously decided to intimate to the urban authority that it was desirable to stop the building of the hospital.

**INSTITUTE OF CERTIFICATED SANITARY INSPECTORS.**—The first annual meeting of the members of this Association was held on the 3rd inst. at the Sanitary Institute, and Mr. Wynter Blyth delivered the presidential address. The institute has for its objects the raising of the status of sanitary inspectors and the advancement of that branch of science which is concerned with the healthy internal arrangements and surroundings of households. Mr. Blyth said the new society was not established in a spirit of rivalry with any other association. It was unwise to trust to local authorities. The assistance of Dr. Newsholme would be of the highest value. They would have to obtain a charter of incorporation. Sir Thomas Crawford, Sir Douglas Galton and others addressed the meeting.

**PADDINGTON-GREEN CHILDREN'S HOSPITAL.**—In aid of the funds of this useful institution, which is greatly in need of help, a sale of fancy work was recently held at Lord Brassey's house in Park-lane. Owing to the large number of out-patients attending the hospital it has been found necessary to build a new wing. The interest of the occasion was enhanced by the opportunity afforded to visitors of inspecting his lordship's Indian museum.

**ROYAL BRITISH NURSES' ASSOCIATION.**—The fifth annual conversazione of this institution was held at Princes' Hall, Piccadilly, on Wednesday evening last, when Princess Christian pinned on the breasts of the new members the Association's bronze cross. The guests were received by Sir J. Crichton Browne, Mr. Pick, Miss Stuart of St. Bartholomew's Hospital and Miss Hogg of the Naval Nursing Hospital. Most of the metropolitan hospitals and many of those in the provinces were represented, the nurses being in uniform. Amusement was provided by Mr. Corney Grain and the performance of the "Bijou" Orchestra under Mr. J. Plougher.

**WESTERN INFIRMARY, GLASGOW.**—During the past year there have been treated in this infirmary 12,442 out-door patients and 3897 in-door. The average period of residence of the in-door patients was 34·37 days; the deaths numbered 312, or 8·03 per cent., but deducting 61, those who died within forty-eight hours after admission, the death-rate becomes 7·2 per cent. The total income (ordinary and extraordinary) for the year amounted to £26,157 6s. 10d.; after meeting all claims, both ordinary and extraordinary, the sum of £1461 9s. was carried to stock account. Each fully occupied bed cost £61 4s. 9½d.; the average cost per patient was £5 15s. 5½d. The Lady Hozier Convalescent Home at Lanark, a gift to this infirmary, containing about fifty beds, is almost ready for occupation, and the directors make an appeal for the £1300 to £1500 needed for its annual maintenance.

**AN INSANITARY BOARD SCHOOL.**—At the Southwark Police-court this week the clerk to the Lambeth vestry appeared to support a summons taken out against the clerk of the London School Board for disregarding notices requiring him to execute certain repairs in order to place the Johanna Board School in a sanitary condition. It appears that at the school in question a rain-water pipe connected with the drain was found to be discharging sewer air four feet below the open windows of the building. Dr. Verdon, the medical officer of health, had visited the school in the early part of 1891 and found the closets to be foul and ill-constructed. Cases of scarlet fever and diphtheria had arisen amongst the scholars, and he was convinced that the infection was due to the want of sanitary arrangements. Asked if the school could not be closed in order to afford time for effecting the proper repairs, the vestry clerk said that in that case the Government grant would be stopped. The magistrate, however, decided that after the expiration of seven days the work necessary must be proceeded with.

**VICTORIA INFIRMARY, GLASGOW.**—From the annual report of this institution, just published, we learn that last year 1081 patients received in-door treatment. Their average period of residence was 25·9 days; the deaths numbered 76, or 7·4 per cent.; but of these 23 cases were of such a nature that death took place within twenty-four hours, and deducting these the death-rate is reduced to 5·1 per cent. The average cost of each fully occupied bed was £60 11s. 1d., and the average cost per patient £4 9s. 3d. These sums would have been much smaller but for the large feu-duty which has to be paid for the site of the infirmary. The out-door patients numbered 9431. The new pavilion at present building will, it is expected, be ready for patients in a few months; this will raise the accommodation to 150 beds. The ordinary income during the year exceeded the ordinary expenditure by £20 7s. 1d.—"a somewhat unusual but most satisfactory experience." Over a fourth of the ordinary maintenance income was subscribed by working men. The interest of working men in this infirmary is kept up by the fact that they elect five of the board of governors from amongst their own number, and it is gratifying to find that the number of works and factories qualified (by the amount of their subscription) to take part in this election is yearly increasing. Taking into consideration all sources of income and all kinds of expenditure, this infirmary has paid its way and added £3416 to its capital account, which now amounts to nearly £16,000.

## Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ANDERSON, F. T., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the No. 4 Sanitary District of the Alton Union, vice Lazenby, resigned.

ANDERSON, W. H., M.B., C.M. Glasg., has been appointed Medical Officer for the No. 8 Sanitary District, Birkenhead.

BAILEY, S. H., M.B., M.S. Aberd., has been appointed Medical Officer for the Fifth Sanitary District of the Nottingham Union, vice Buckoll, resigned.

BODY, H. M., M.R.C.S., has been reappointed Medical Officer of Health for the Crediton Urban Sanitary District.

BURTON, DR., has been reappointed Medical Officer of Health for the Greenford Rural Sanitary District.

CALLAGHAN, THOS., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Cork Dispensary District, vice Townsend, resigned.

DERAVIN, E. A., M.B., B.Ch. Melb., has been appointed Assistant Medical Officer of the Bendigo Hospital, Victoria, Australia.

DERRY, B. G., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health for the Bodmin Urban Sanitary District.

DOLAMORE, W. H., L.R.C.P., M.R.C.S., L.D.S., has been appointed Second Dental Surgeon to the Westminster Hospital.

EDEN, W. A., L.S.A., has been appointed Assistant Medical Officer of the Infirmary, St. George's Union, vice Tompsett, resigned.

EVANS, WILLIAM, L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Health for the Anglesey Rural Sanitary Districts.

ELLIOTT, HARRY SCOTT, M.R.C.S., L.R.C.P., L.S.A. Lond., has been appointed Assistant House Physician to St. George's Hospital.

EWING, S. A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Resident Medical Officer of the Victorian Eye and Ear Hospital, Melbourne, vice Shuter, resigned.

FRASER, PETER, M.D., M.S., B.Sc. (Public Health) Edin., has been reappointed Medical Officer of Health for the Llangefni Urban Sanitary District.

FUSSELL, E. F., M.B. Aberd., M.R.C.P. Lond., has been reappointed Medical Officer of Health for East Sussex.

GARDNER, W. T., M.B. Lond., M.R.C.S., L.R.C.P., has been appointed Medical Officer of Health for Acton.

GAULT, DAVID, L.R.C.S., L.R.C.P. Edin., has been appointed an additional Public Vaccinator for the District of Pahiatua, New Zealand.

GILPIN, F., M.B. C.S., has been reappointed Medical Officer of Health to the Stratford-upon-Avon Town Council.

HEARD, C. DE WOLFE, M.B. Melb., L.R.C.P., L.R.C.S. Edin., has been appointed a Public Vaccinator for Macarthur, Victoria, Australia.

HOOPER, F. L., M.R.C.S., has been appointed a Public Vaccinator and Health Officer for Morningside Shire, Victoria, Australia.

HUMPHREYS, J., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Trawsfynydd Sanitary District of the Festiniog Union.

MALVIN, M., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Eastern Sanitary District of Scarborough.

MILLARD, E. J., M.B., Ch.M. Sydney, has been appointed Junior Resident Medical Officer of the Hospital for the Insane, Paramatta, New South Wales, vice Scott, resigned.

MIRBACH, RUDOLPH, M.D., Ch.D. Munich, has been appointed an additional Public Vaccinator for the District of Waipawa, New Zealand.

MITCHELL, H. ST. JOHN, L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator for Swan Hill, Victoria, Australia.

MORSE, EDWARD, L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer of Health for Torrington.

MULLALLY, W. T., M.D., M.Ch. Qu. Univ. Irel., L.M. K.Q.C.P. Irel., has been appointed Health Officer to the Council of the Shire of Ballarat, Victoria, Australia.

OLDMEADOW, L. J. H., M.B., C.M. Edin., has been appointed Assistant House Surgeon to the Northern Hospital, Liverpool.

PEEBLES, F. M., M.B. Melb., has been appointed Resident Medical Officer of the Bendigo Hospital, Victoria, Australia.

PULLIN, T. H. S., M.D. St. And., F.R.C.S. Edin., M.R.C.S., has been reappointed Medical Officer of Health to the Sidmouth Local Board.

RYAN, T. F., M.B. Melb., has been appointed Health Officer for Lawloit Shire, Victoria, Australia.

SHOWMAN, L. F., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator for Birchip, Victoria, Australia.

SHUTER, R. E., M.B., Ch.B. Melb., has been appointed Resident Medical Officer of the Melbourne Hospital, Victoria, Australia.

SMITHIES, J. J., L.F.P.S. Glasg., L.R.C.P. Edin., has been appointed Medical Officer for the Gisburn Sanitary District of the Clitheroe Union, vice Lazenby, resigned.

SOUTHBY, A. J., M.R.C.S., has been reappointed Medical Officer of Health to the Slough Local Board.

TENNANT, T. H., L.F.P.S. Glasg., has been appointed Government Medical Officer and Vaccinator for the District of Hillston, New South Wales.

URQUHART, C. T. D., M.B., C.M. Aberd., has been appointed Physician to the Hospital for Incurables District, Aberdeen.

WILLIAMS, G. R., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Fourth Sanitary District of the Henstead Union.

WALL, M. E., M.D. Munich, has been appointed a Public Vaccinator for Bannockburn, Victoria, Australia.

WILSON, J. F., M.D., M.Ch. Irel., has been appointed Medical Officer of Health for the Meriden, Rugby, Solihull, Southam and Warwick Unions, and the Kenilworth, Rugby and Warwick Urban Sanitary Districts.

WRIGHT, HENRY, L.R.C.P., J.M. Edin., has been reappointed Medical Officer of Health for the Gainsborough Rural Sanitary District.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BELGRAVE HOSPITAL FOR CHILDREN, 70, Gloucester-street, S.W.—House Surgeon. Board, lodging, fuel and light found.

BRIDGWATER INFIRMARY.—House Surgeon. Salary £80 per annum, with board and residence.

GENERAL HOSPITAL, Birmingham.—Assistant House Surgeon, for six months. Residence, board and washing provided.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's-inn-road, W.C.—House Surgeon. Rooms, coals and lights provided.

LEEDS PUBLIC DISPENSARY, New Briggate.—Junior Resident Medical Officer. Salary £85 per annum.

MANCHESTER SOUTHERN AND MATERNITY HOSPITAL.—Resident House Surgeon.

NEW HOSPITAL FOR WOMEN, 144, Euston-road.—Two Clinical Assistants for the Out-patient Department, for one year.

NEW HOSPITAL FOR WOMEN, 144, Euston-road.—Two qualified Medical Women as Assistant Physicians in the Out-patient Department, for two years.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill, Stoke-upon-Trent.—House Surgeon. £120 per annum, increasing by £10 a year at the discretion of the Committee, with furnished apartments, board and washing.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon, for six months. Board, lodging and washing provided, with prospect of an honorarium of £10 10s.

ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £150, with furnished apartments, fire, light and attendance.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—Senior House Surgeon. Salary, with board and residence, £75 per annum.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—Clinical Assistants for six months.

ROYAL UNIVERSITY OF IRELAND, Dublin.—Examiner in Ophthalmology and Otology.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Junior Assistant-House Surgeon. Salary £57 per annum, with board, lodging and washing. (Applications to Dr. Crochley Clapham, Hon. Sec. Medical Staff, the Grange, near Rotherham.)

STOCKPORT INFIRMARY.—House Surgeon. Salary £100 per annum, with board and apartments.

UNIVERSITY OF EDINBURGH.—Five Examiners.

VICTORIA HOSPITAL, Folkestone.—House Surgeon, unmarried. Salary £80 the first year, with an increase of £10 yearly for the following; two years, together with board and residence.

## Births, Marriages and Deaths.

### BIRTHS.

BIGGER.—On Dec. 4th, at Queen's-park-gardens, Streatham-common, the wife of Dr. W. Grimshaw Bigger, of a son.

BODILLY.—On Dec. 2nd, at Grove-road, South Woodford, Essex, the wife of Reginald Thomas Hacker Bodilly, L.R.C.P., M.R.C.S., of a son.

ROBERTS.—On Nov. 29th, at Melton-under-Wychwood, Oxon., the wife of Henry Roberts, M.R.C.S., of a daughter.

TAIT.—On Nov. 28th, at Highbury-park, the wife of Edward Sabine-Tait, M.D., of a son.

### MARRIAGES.

DOWNIE—OGILVIE.—On Dec. 6th, at Buckingham-terrace, Edinburgh, Kenneth Mackenzie Downie, M.D., Indian Medical Service (Bengal), to Margaret, youngest daughter of the late James Ogilvie, Esq.

GORDON—REED.—On Oct. 6th, at Clunes, Victoria, Australia, by the Rev. Elder Gray, B.A., Arthur H. Gordon, M.R.C.S. Eng., A.K.C. Lond., youngest son of the Rev. J. B. Gordon, formerly Prebendary of Doon, to Elizabeth Scott, widow of the late Arthur Reed, of Clunes.

LYNDON—CLEMENTS.—On Nov. 30th, at St. Peter's Church, Eaton-square, George Ernest Lyndon, M.R.C.P., L.R.C.S. Irel., of Pembroke-gardens, Bayswater, to Lady Selina Clements, fifth daughter of the late Hon. and Rev. Francis Clements and sister of the late Earl of Leirrim.

PEARCE-THOMAS—DAWSON.—On Nov. 30th, at St. Nicholas Church, Brighton, by the Rev. Canon Haddock, Vicar of Clapham, Bedfordshire, assisted by Rev. C. W. Bond, Vicar, W. Pearce-Thomas, M.B., C.M., Heckmondwike, Yorks, to Alice Mary, daughter of the late Rev. J. F. Dawson, The Woodlands, Bedford, and 1, Vernon-terrace, Brighton.

SMART—CADDY.—On Nov. 29th, at St. Luke's Church, Kew-gardens, William Herbert Smart, M.D., of Polesworth, Warwickshire, to Florence, elder daughter of Dr. Caddy, D.I.G., Royal Navy, of the Charterhouse, Lion-gate-gardens, Richmond.

WEBB—GOADBY.—On Dec. 1st, at Christchurch, Sandown, Isle of Wight, Sidney Roberts Webb, M.D., second son of Conrade E. Webb, of Hampstead, to Agnes Phoebe, second daughter of Major S. H. Goadby, of Sandown.

WREFOED—GUERRIER.—On Dec. 7th, at the Parish Church of St. Peter, Woking, John Wrefoed, L.R.C.P., M.R.C.S., third son of the late Samuel Wrefoed, of Exeter, to Emma Mary Joynton Guerrier, younger daughter of H. J. Guerrier, Esq., of Colville, Woking.

## DEATHS.

- HADAWAY.—On Dec. 6th, at Garlinge, Westgate-on-Sea, Dr. James Hadaway, formerly of 47 B, Welbeck-street, Cavendish-square, aged 78.
- ROWLANDS.—On Nov. 28th, at King-street, Carmarthen, James David Rowlands, M.B.C.S., eldest son of James Rowlands, F.R.C.S.
- SHONE.—On Dec. 3rd, at East Sheen, S.W., of pneumonia, Richard Lewis Shone, Surgeon, aged 60 years.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages and Deaths.*

## Medical Diary for the ensuing Week.

## Monday, December 12.

- KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays, at the same hour.
- ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; and on Tuesday, Wednesday, Friday, and Saturday at the same hour.
- ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M.; and each day at the same hour.
- CHELSEA HOSPITAL FOR WOMEN.—Operations, 2 P.M.; Thursday, 2.
- HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.; and on Thursday at the same hour.
- METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
- ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.
- CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
- UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M. Thursday, 9 A.M. Eye Department, 2.
- MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. A. Ernest Sanson: The Irregular Heart—a Clinical Study

## Tuesday, December 13.

- GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
- ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
- ST. MARK'S HOSPITAL.—Operations, 2 P.M.
- CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
- WESTMINSTER HOSPITAL.—Operations, 2 P.M.
- WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
- UNIVERSITY COLLEGE HOSPITAL.—Skin Department, 1.45; Saturday, 9.15.
- ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electrotherapeutics, same day, 2 P.M.
- ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Dr. Arthur H. N. Lewers: On some points in the Supra-vaginal Amputation of the Cervix Uteri for Cancer, with special reference to the methods adopted in cases where for two years and upwards the disease has not recurred.—Dr. A. Haig: The Effects of the Iodides on Arterial tension and the Excretion of Urates.

## Wednesday, December 14

- NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 10 A.M.
- MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.
- CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.
- ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
- LONDON HOSPITAL.—Operations, 2 P.M.; Thursday and Saturday, same hour.
- ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.
- SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
- GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
- UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M. Dental Department, 9.30. Eye Department, 2.
- ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
- CHILDREN'S HOSPITAL, GREAT ORM-ND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.
- HUNTERIAN SOCIETY (London Institution).—8.30 P.M. Pathological Evening. Dr. James Galloway: Protozoa as Causes of Disease (with Lantern Demonstration).—Dr. Arnold Chaplin: Specimens showing Induration of the Lungs.—Dr. Charleswood Turner, Mr. C. J. Symonds and Mr. J. Poland will also exhibit Specimens.

## Thursday, December 15.

- ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
- UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M. Ear and Throat Department, 9 A.M. Eye Department, 2.
- CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road).—5 P.M. Dr. Dundas Grant: Affections of the External Meatus.
- HARVEIAN SOCIETY.—8.30 P.M. Mr. Field: The Pathology and Treatment of Suppurative Diseases of the Ear. (Third Harveian Lecture.)
- NEUROLOGICAL SOCIETY OF LONDON (National Hospital for the Paralysed and Epileptic, Queen-sq.).—8.30 P.M. Dr. Batten (introduced by the President): Facial Hemiatrophy.—Dr. Buzzard: Case with Anomalous Nervous Symptoms.—Dr. Pitt: Muscular Atrophy, with Hypertrophy of Neck Muscles.—Dr. Ferrier: Syringomyelia. And other cases.

## Friday, December 16.

- ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
- UNIVERSITY COLLEGE HOSPITAL.—Eye Department, 2.
- LONDON SKIN HOSPITAL (40, Fitzroy-sq., W.).—3 P.M. Dr. E. J. Barry: Psoriasis and its Treatment.

## Saturday, December 17.

- UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

METEOROLOGICAL READINGS.

Notes, Short Comments & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET to be addressed "To the Publisher."

We cannot undertake to return MSS. not used.

COMMUNICATIONS relating to the EDITORIAL business of THE LANCET must in every case be addressed exclusively "To the Editors," and not to them otherwise than in their official capacity.

RECURRENCE OF MEASLES.

Mr. Leonard S. Barnes, M.R.C.S., L.R.C.P. (Whitwell, Herts.), writes:—

"A severe epidemic of undoubted measles broke out in August and September last in this and neighbouring villages. All the schools were closed. This November the epidemic has returned, and with a few exceptions all the children have had it again, but more severely than in the last epidemic, several children dying of broncho-pneumonia. In this village out of 183 children 171 have had measles, nearly the same proportion as last August. Also in this last epidemic a great many adults who had had it in younger days caught the infection again. The first epidemic was typical of morbilli in every symptom and in the incubation and appearance of rash. I should like an explanation if anyone would forward me one."

\*\* Although from time to time undoubted instances of recurrence of true measles are met with, even at a short interval, yet we are unaware of any widespread recurrence similar to that observed by Mr. Barnes. Is it possible that the first and milder cases were cases of röteln?—ED. L.

Mr. J. P. Long.—A list of the most recent literature on the subjects of pharmacology and therapeutics is given in our Students' Number, Sept. 3rd, 1892.

HÆMORRHAGE AFTER TOOTH EXTRACTION—ITS ARREST.

To the Editors of THE LANCET.

SIRS,—I have seen but two cases of serious hæmorrhage after tooth extraction. In both of these cases the plugging of the cavity with a piece of wool soaked in turpentine was at once rapid and effectual; and I think this treatment, which I owe to my teachers, is worthy of being more widely known. I am, Sirs, yours faithfully,

Aldersgate-street, E.C., December, 1892. R. MCINTOSH, M.B.

USE OF TITLES.

R. J. W.—The title mentioned—M.B.—implies the possession of a University degree in medicine, and many of our correspondent's friends will give him, in courtesy, the title of doctor; but he will do well not to assume it as a right. His titles appended to his name are its best ornament. The title of "Doctor" appertains to various faculties.

THE VIENNA MEDICAL SCHOOL.

We have been favoured by an occasional correspondent with a sketch or résumé of the advantages which may be derived by a newly qualified practitioner from a sojourn of a few months in either Berlin or Vienna, preferably the latter. A short abstract of the communication can only be given here. *In limine*, a knowledge of the German tongue, or at least a working acquaintance with it, is almost indispensable to one who is desirous of pursuing the study of one or other of the ancillary branches of medicine and surgery. In Vienna every subject is taught in classes. Before the student can attend any course he has to matriculate in the university, which means simply sending in a paper with various items of information in it concerning birth-place, religion &c. Then, having decided what courses he proposes to attend, he fills in more papers and, as a rule, prepays the fees for them at the university. A difference is usually made between qualified and unqualified men, the former being generally charged a higher fee for a course than the latter. An advantage may be obtained in Vienna, as compared with London, in that a student can attend private classes limited to four or five men, whom a *privat docent* will teach and to whom he will show cases (spoken of as "material"). These patients are paid so much per hour for submitting to examination. By means of this system a large number of cases may be seen in a short time. The subjects which can with most advantage be studied are diseases of the throat, of the ear and of the skin. Gynecology can also be fairly well studied in the Austrian capital. Bacteriology, however, is better learnt in Berlin than in Vienna. In some of the clinics, moreover, especially the smaller ones, exceptionally interesting cases are retained and come up periodically for examination by the students. Living in Vienna is not expensive; comfortable board and lodging may be had there at a cost of £2 2s. per week. In conclusion, it may be stated that if a student has only a short time at his disposal and wishes to get some experience in diagnosis in three or four special diseases, he will do well to spend that time in Vienna, and if on his arrival there he applies to the Secretary of the Anglo-American Medical Association, he will at once be supplied with, or put in the way of obtaining for himself, all the information he requires for his purpose.

Mr. J. G. Williamson, M.B.—Their name is legion. Among the leading ones are: *New York Medical Record*, *New York Medical Journal*, *Boston Medical and Surgical Journal*, *Medical News* (Philadelphia).

ENGLISH PRACTITIONERS ABROAD.

To the Editors of THE LANCET.

SIRS,—Sir Richard Quain, in his address at the General Medical Council, draws attention to the illiberal legislation respecting the practice of medicine by English medical men in France and Switzerland. As one who has run the gauntlet of heavy fines, permission to practise, retraction of permit, and, finally, the expense and loss of time in passing the Swiss examinations, I should like to point out yet another obstacle in the way of practice abroad, besides the examinations to be undergone. I refer to the taxation imposed on income. What the French scale is I am unable to say; but here, in Davos, the taxes on an income of 12,000 francs amount to 13.75 per cent. cantonal tax and about the same for local taxation. Roughly, that means paying six shillings out of every guinea. All incomes are treated alike, native and foreign. The scale begins at 1 or 2 per cent. on small incomes, but when 12,000 francs (about £377) are reached the taxation amounts to the sum I have stated. I am, Sirs, your obedient servant,

A. TUCKER WISE, M.D.  
(Diplôme Suisse Fédéral).

Davos Platz, Switzerland.

"INVESTIGATIONS INTO THE ETIOLOGY OF MEDITERRANEAN FEVER.

Surgeon-Captain M. Louis Hughes (Malta) adds the following note to the paper on this subject which appeared in our last issue:—"Since forwarding this paper three more fatal cases of this fever have come under my notice, in all of which I have been able to demonstrate the presence of this micro-organism, both by cultivations and in cover-glass preparations of fresh splenic substance."

PHOTOGRAPHS AND TESTIMONIALS.

To the Editors of THE LANCET.

SIRS,—Will you call attention through your columns to a decided grievance of qualified assistants who reply to advertisements? Some time ago I replied to one. With my reply I forwarded a copy of testimonials and enclosed a stamped and addressed envelope for their return. From that day to this I have not seen either my testimonials, envelope or stamps. Surely, in the name of honesty, when a stamped addressed envelope is enclosed it is only just to return testimonials. The same applies to photographs, which are frequently advertised for but, as far as my experience goes, never returned.

I am, Sirs, yours faithfully,

Dec. 7th, 1892.

AGGRAVATED (M.B.).

## METHOD OF MOUNTING SPUTUM.

MR. W. R. LAKE, F.R.C.S., submits to us a description of a method he has employed for preserving sputum containing tubercle bacilli, though, as he states, the method may have been already adopted with respect to other tissues. The following is the description of the process:—"The sputum to be preserved is put into a 5 per cent solution of corrosive sublimate, in which it can be kept for three weeks or more; but before using a specimen it should be transferred for some hours to normal saline solution, or the whole may be kept in a weak solution of corrosive sublimate in the normal saline solution. The next step consists in placing a small piece of the coagulated mucus on a cover glass after drying with filter paper and adding a few drops of a 1 in 2 solution of iodide of potassium, coloured slightly with iodine. As the secretion becomes coloured it softens; the excess of fluid is removed by filter paper and the sputum squeezed between two cover glasses in the usual way, dried and stained with Gabbet's stain. This method also enables one to keep a specimen to prove the efficacy of doubtful staining fluid."

Mr. G. S. Smith, B.Sc.Lond.—Our correspondent must be aware that there are many possible explanations for the discordant results, in view of the varying conditions of time and place as well as the differences in individual modes of thought and appreciation.

## NEW SOURCE OF LEAD POISONING.

To the Editors of THE LANCET.

SIRS,—I have lately had my attention drawn to a new source of lead poisoning. A considerable number of men are now employed by the manufacturers of storage or secondary cells (used for electric lighting and other purposes) in making, cleaning and recoting the plates. The usual form of plate is a lead plate coated with red lead, but latterly cells have been introduced for the purpose of driving and lighting vehicles of various kinds, where lightness is an object, to meet which requirement the plates are made by compressing in a mould a mixture of sulphuric acid and red lead. The superfluous material which escapes from the mould is wiped off by hand apparently in many cases. This could be easily avoided, but it seems difficult for the men to escape getting the material on their hands during some part of the process, and I am told that during the mixing of the red lead and sulphuric acid a great deal of finely powdered red lead flies about and is inhaled. Most if not all the men seem to do their work with their hands unprotected, and one man came to me with his hands still showing traces of the red lead which he had been using.

The precautions which suggest themselves are extremely simple: the wearing of a thick leather or indiarubber glove in coating and making the plates and a respirator during the mixing process, as well as the enforcement of the usual rules as to cleanliness in eating and the use of sulphuric acid drinks, if the poisoning take place in that way and not by absorption through the skin. I believe many observers do not consider the latter method of introduction a likely one. As the manufacture of such batteries is of recent origin it is extremely likely that the employers do not think of the risk they are putting the men to, and the men being poorly educated (as the work is quite simple) and not following a trade with traditions, as in the case of painters and plumbers, may not have even heard of lead poisoning. I have seen three such cases during the last few weeks at the Westminster Hospital, all coming from the same employers; and I understand from one of them that out of thirteen men employed by his firm in making plates, four of them have suffered from lead poisoning in six months. During the last eighteen months I have seen two or three others from various works, so the carelessness is not peculiar to one firm.

I think that the matter is sufficiently serious to have attention called to it, seeing that plumbism is such a very unpleasant affection in its immediate consequences as well as serious in its remoter results, and at the same time easily avoided, if only those who are chiefly concerned will take the trouble to enforce precautions which are so simple in themselves.

I am, Sirs, yours truly,  
Lower Seymour-street, W., Nov. 28th, 1892. W. A. WILLS, M.D.

## MEDICAL ADVERTISING IN BANGALORE.

WE insert with much regret an advertisement in an Indian newspaper, the *Bangalore Spectator*, by a medical man, whose prizes might have been expected to raise him above either the disposition or the need to resort to such unprofessional methods of making his merits known.

"C. G. R. Naylor, M.R.C.S. Eng., L.R.C.S. and P. Edin., late resident surgeon, Royal Maternity Hospital, Edinburgh; twice prizeman in midwifery and diseases of women and children; general medical practitioner and accoucheur. Open to engagement or consultation. Address, 'Charlton Hall,' No. 1, Magrath-road, near Daily Post Press."

M.R.C.S. Eng.—Our correspondent will find both subjects fully treated in Ziemssen's System of Therapeutics, of which an English translation was published a few years ago (Smith, Elder and Co.). The most recent manual on Medical Electricity is that by Stevenson and Jones (H. K. Lewis).

## THE "TELEPHONE EAR."

WE hardly needed Mr. Rudyard Kipling's vivid sketch of the life passed at the end of a telephone by the American millionaire in summer quarters to bring before us that latest outcome of a too keenly competitive civilisation, the "telephone ear." That particular neurosis, which seems, in the *New World* at least, to be earning a place in classification with the "lawn tennis leg," had already been foreseen and described by Professor Lannois of the Lyons Medical School. For ears which are not especially sound he considers the telephone to be quite contra-indicated, as even in a comparatively robust organ its continuous use is followed by symptoms more or less grave—cephalalgia, vertigo, hyperesthesia, insomnia and sometimes psychical disturbances of a character which might become chronic. He counsels a sparing use of the instrument in the case of those whose ears are sound and an absolute abstention from it in those whose organs are already impaired from causes hereditary or induced. His memoir, which was read and discussed in a confirmatory sense at the Congress of Aural Surgeons held in Paris in 1880, will be found in the "*Comptes Rendus et Mémoires*," p. 265, for the same year.

W. B.—We believe our correspondent could not do better than consult Dr. Thresh of Chelmsford, the county health officer.

## A FINGER GUARD.

To the Editors of THE LANCET.

SIRS,—May I draw attention, through the medium of your columns, to a new form of finger guard which has been made for me by Messrs. Maw, Son and Thompson? It is made of the thinnest possible rubber and rolled up, so that it can be applied to the finger in a moment. I have used these guards for the last six months in my outpatient clinic at the Lock Hospital with great comfort. The rubber is so thin that the slightest induration can be appreciated, and I need hardly insist on the importance of diagnosing an infecting sore at the earliest possible moment. The fingers are most easily cleansed and sterilised after each examination without corroding the surgeon's skin or risking the infection of the next patient. To those surgeons who have to examine a number of cases in a limited time, the old-fashioned precautions—bits of lint &c.—are impossible, and if no precautions be taken infection is merely a matter of time. I can strongly recommend these guards to all surgeons and gynaecologists.

I am, Sirs, yours faithfully,

Hertford-street, W., Nov. 1892.

ARTHUR H. WARD.

## HISTOLOGICAL RESPIRATION TEST.

IN an article in the *Boletín Médico de Puebla* on a new method for determining whether a child has breathed, Dr. Moreno points out that the epithelium of the alveoli of the lungs before birth is of a cubical character, but that after respiration has taken place it is flattened out into the ordinary tessellated variety. In order to determine whether this change has or has not occurred he injects a solution of nitrate of silver of the strength of 1 in 800 into the bronchus, which is then tied, and the whole lung suspended in the same silver solution for some hours. It is then dried, washed with distilled water and hardened in spirit, during which, being exposed to the action of light, the inter-epithelial cement reduces the silver salt and becomes blackened, so that the outline of the cells can be made out. Sections are then made and a solution of chloride of sodium employed to wash away any excess of silver. The sections are mounted in glycerine and examined.

Dr. R. McLeod (Upper Norwood).—The paper was duly received and is marked for publication.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

## During the week marked copies of the following newspapers

have been received:—*The Morning, Natal Witness, Cork Examiner, Leith Express, Dundee Advertiser, Coventry Herald, Medical Monthly, Times of India, Health, English Mechanic, Keighley News, Public Opinion, Flintshire Observer, Scientific American, Optician, Leeds Mercury, Scottish Leader, News of the World, Court Circular, Liverpool Daily Post, Sunday Times, Indian Engineering, Horncastle News, Irish Times, Blackburn Standard, Yarmouth Independent, Leicester Daily Post, Liverpool Mercury, Ipswich Journal, Western Morning News, Freeman's Journal, Trowbridge Chronicle, Medical Record (New York), Shield's Daily Gazette, Birmingham Daily Post, West Middlesex Standard, Surrey Advertiser, Hertfordshire Mercury, Mining Journal, Bristol Mercury, Insurance Record, Local Government Chronicle, City Press, Yorkshire Post, Reading Mercury, Weekly Free Press and Aberdeen Herald, Guy's Hospital Gazette, Local Government Journal, Builder, Architect.*

Lectures

ON THE

PHYSIOLOGY AND PATHOLOGY OF  
BLOOD DESTRUCTION.

Delivered in the Examination Hall, Victoria Embankment,  
on Nov. 22nd & 29th, 1892,

By WILLIAM HUNTER, M.D. EDIN.,  
M.R.C.P. LOND. &c.,

ASSISTANT PHYSICIAN TO THE LONDON FEVER HOSPITAL; LATE  
SANITARY RESEARCH SCHOLAR, GROCERS' COMPANY.

LECTURE II. — (Concluded.)

GASTRO-INTESTINAL CAPILLARIES AS A SEAT OF  
HÆMOLYSIS.

THE spleen being thus apparently the chief seat of hæmolytic change, one naturally inquires where this change takes place after its removal. As regards blood pigment, the place of the spleen is then taken, I find, partly by red bone marrow, partly by the capillaries of the liver (Experiments 64, dog, and 89, rabbit), the amount of pigment within the capillaries of the liver being greater than ever observed under any other circumstances. Pigment alone has, however, as we have seen, but a limited significance in this relation, and this is again found to hold good. For my observations show that, after removal of the spleen, it is not the capillaries of the liver, but those lying at the other end of the portal area—namely, within the gastro-intestinal mucosa—that constitute the chief seats of hæmolytic change. The evidence I can adduce in support of this view is naturally much less conclusive than it was in the case of the spleen, on account of the widespread area over which these capillaries extend.

This evidence is of the following nature. When destruction was moderate in amount the blood of the mesenteric veins showed no changes, while that of the splenic vein showed, it might be, extremely marked changes (Experiments 78, 80, 86 and 87). If the degree of destruction were greater, slight changes were found, but much less pronounced in character than those in the splenic vein (Experiment 82). In short, when the spleen was present it was exceptional to find changes in the blood issuing from the gastro-intestinal tract, even when a considerable hæmolytic change had been experimentally induced. After removal of the spleen, on the other hand, this was the rule even with a considerably less hæmolytic change.

Not only were changes more frequently met with, they were more various and extensive in their character. While in the normal animal they comprised at most the presence of an excess of albuminous granules, in the spleenless animal they included not only a much larger number of both granules and spherules, but also—what formerly had never been found—large pigment cells enclosing red corpuscles and red corpuscles in process of active disintegration, oozing out of their stroma and breaking up into coloured spherical bodies. Such changes had previously been entirely confined to the blood of the spleen and the splenic vein (Experiments 62, 64 and 77). They comprised, moreover, a still more significant change, one to which I have as yet made no reference—namely, a very large increase in the number of leucocytes, fourfold or fivefold increase (Experiment 64, dog)—a change never observed to the same degree even in the splenic vein, to which it formerly was mainly confined (Experiment 121, dog). Obviously therefore some of the changes mainly confined to the spleen in the normal animal were after its removal carried out within the much wider area of the gastro-intestinal capillary tract. Surprising as this result at first seemed, it ceased to be so in the light of the facts afterwards ascertained. For with regard both to its extent and the mass and activity of the cells, both epithelial and lymphoid, lying in closest relation to it, the capillary area of the gastro-intestinal mucosa may fitly be regarded as an organ second in size and functional activity to none in the body, not even excepting the liver. Difficult as I felt it to be then to explain why the destructive action of a drug like toluylendiamine should apparently be more marked in this area than in another, I nevertheless concluded that such was

No. 3616.

the case. My difficulty was cleared up when, as will presently be seen, I found that it was activity of cells more than any other factor that determined the occurrence of hæmolytic change even after the injection of a destructive agent like toluylendiamine.

I conclude, then, that second only in importance to the spleen, the gastro-intestinal capillary area is the most important seat of hæmolytic change. I place it second to the spleen for the reason that when the spleen is present, the changes in the blood coming from this area are altogether less marked than those found in the splenic vein. I place it before the capillary area of the liver; partly because the chief changes after removal of the spleen are presented by the blood issuing from the gastro-intestinal area, and are of the same character as those previously found in the splenic vein; and partly because as regards their mass, their character and their activity, the cells lying in relation to the capillary area resemble more closely those within the spleen, than do those in relation to the liver capillaries.

RÔLE OF THE LIVER IN HÆMOLYSIS.

To sum up the results of my observations with regard to the chief seats of hæmolytic change. In their order of importance, the seats are: (1) The spleen; (2) the gastro-intestinal capillary area; (3) the capillaries of the liver; and lastly (4) the red bone marrow. All of these have two features in common of capital importance—namely, comparative slowness of the circulation and a large mass of active cells lying in close relation with the blood. With the exception of the bone marrow—and I regard it of little importance in comparison with the others—all the other seats are in connexion with the portal circulation and pour their blood into it. In all cases therefore the products of hæmolytic change, whatever be their nature, have to pass through the liver before they reach the general circulation. It is then that the chief rôle of the liver in relation to hæmolytic change becomes in my opinion manifest. A certain amount of hæmolytic change may take place in its capillary area as the result of the activity of the mass of leucocytes contained within it, and to a certain extent also it may be the activity of the liver cells adjacent to it. Still the chief function of the liver is not in inducing hæmolytic change, but getting rid by excretion or otherwise of the products of hæmolytic change. Amongst the most abundant of these is hæmoglobin. Set free within the spleen and in the gastro-intestinal capillary area (as we shall presently see by the activity of the cells lying in these areas), it is carried to the liver, passed through the endothelial cells of the walls of the capillaries and taken up by the liver cells. It is here broken up, the usual products of this destruction being the bile pigments and a small trace of iron daily excreted in the bile (Young, Kunkel, Hoppe-Seyler, Baserin and Novi). Sometimes in addition to these, but, in my opinion, not necessarily constantly, a trace of blood pigment remains behind in the liver cell. The morphological products of destruction—the granules and spherules &c.—are likewise arrested in passing through the liver, and prevented from passing into the general circulation, not, however, through the agency of the liver cells, but through that of the leucocytes within the capillaries. I conclude from the frequency with which I have found elements of this kind and pigment cells in the capillaries of the liver and in the portal area, while none were to be found in the general circulation during life or in the systemic veins after death, that the power thus possessed by the leucocytes and endothelial cells of the liver is a very considerable and an important one.

The description I have given of the seats, and by anticipation also of the nature, of hæmolytic change thus in many respects from the conceptions regarding this process with which we started. And in no respect more so perhaps than with regard to the rôle of the liver in hæmolytic change. Hitherto the first place has been tacitly assigned it in this relation. The rôle of the spleen (and other organs) has been called in question either on the ground that no diminution was discoverable in the number of red corpuscles issuing from it, or that no free hæmoglobin could be detected in the blood of the splenic vein (Schäfer). But as regards the liver, if any organ were specially concerned in hæmolytic change more than another, that organ was admittedly the liver, and the destruction was, moreover, effected in some way or other through the agency of the liver cells.

One of the results of this investigation has been, in my estimation, the overthrow of the liver from this position of supremacy and its relegation to another, doubtless still very

important, but nevertheless somewhat humbler sphere of action—namely, that of an excretory organ. And instead of hæmolytic action occurring in the blood generally, and not in any particular organ, we have shown that it is confined almost exclusively to the *portal* as distinguished from the *general* circulation; and moreover, that its two chief seats within this area are first the spleen and secondly the gastro-intestinal capillary area. Lastly, instead of it being an occasional process, consisting in a slow change in the blood, evidenced in the case of the red corpuscles by their gradual loss of elasticity and loss of function, we have seen that hæmolytic action is a daily process involving a daily liberation of a certain amount of hæmoglobin into the plasma of the blood, and its conversion into bile pigments through the agency of the liver cells.

### III. NATURE OF HÆMOLYSIS.

In ascribing such an importance to the activity of cells lying in close relation to the blood, I am anticipating somewhat, for no evidence in support of this has as yet been adduced.

The next object of my investigation was to ascertain why hæmolytic action should be confined to the *portal* as distinguished from the *general* circulation, and why, in particular, the removal of the spleen should so materially affect the action of a destructive agent injected directly into the general blood. In arriving at a solution of this problem I encountered at the outset considerable difficulties, which I vainly at first endeavoured to overcome. The destructive action of the poison, as I satisfied myself time after time, was so obviously intensified within the spleen—sometimes, indeed, confined to that organ—that my first surmise was that the poison had accumulated in the spleen in greater quantity than elsewhere. I therefore sought for a method by which I could detect the presence of toluylendiamine even in the smallest quantity. I thought at one time I had found such a method in the use of benzoyl-chloride—an agent which, as I found, formed a bulky compound with toluylendiamine. On being put to the proof, however, the method failed me. It became then clear to me that the only method by which I could hope to attain my end must be a colorimetric one. After a time such a one I found—a reversal of that usually employed for the detection of nitrites in drinking-water. Phenylendiamine gives with nitrites after adding a drop of dilute hydrochloric acid a deep characteristic colour reaction. If phenylendiamine could be thus used to detect the presence of nitrites it was clear that the process might be reversed and that nitrites could be used to detect the presence of phenylendiamine, or also, as I now found, of toluylendiamine.

After a number of trials and failures I succeeded in working out a method based on this principle for the detection and estimation of toluylendiamine even in minute traces in the blood and other tissues. The delicacy of the colour reaction was such that I found I could estimate the substance even to a hundredth of a milligramme. Thus, out of 10 milligrammes of the substance added to the entire blood of an animal received into 50 cc. of a 10 per cent. NaCl solution I found on estimation 9.95 milligrammes—viz., 9.75 in the plasma, and 0.2 milligrammes in the corpuscles (Experiment 132).

I made use then of this method in another series of experiments both on rabbits and dogs, in which the amount of toluylendiamine in the various tissues and excretions was estimated at intervals of time after its injection, varying from one hour up to eighteen.

The results were as follows. In the first place I found not the slightest support to the view that the drug accumulates in the spleen in greater amount than elsewhere; on the contrary, even three hours after injection of half a gramme of toluylendiamine the amount found in the spleen was too small to be estimable—less even than in blood, liver or kidneys (Experiment 126). I found, however, what to me was even more instructive than this, absence of toluylendiamine from the spleen—namely,

(1) That even within the short space of one hour after its injection the total amount of the substance present in the blood rarely exceeded one milligramme and was generally less, even after injection of quantities of half a gramme (Experiments 119 and 125, dog, 126, 128 and 135, rabbit).

(2) That the organs containing most of the substance were those concerned in excretion—namely, the liver and kidneys;

(3) Lastly, and most important of all, that in passing through the body almost the whole of the toluylendiamine was broken up, only an eighteenth or twentieth part of it being accounted for in the urine and bile excreted subsequently to its injection (Experiments 121, dog, and 135, rabbit).

For this last result I was quite unprepared. For toluylendiamine is a remarkably stable body, and it had never occurred to me as possible, still less probable, that it could be thus broken up. The fact however that it is so supplies, I think, the key that is wanting to the explanation of the remarkable effect of removal of the spleen on its action.

### DIRECT AND INDIRECT ACTION OF POISONS ON THE BLOOD.

I desire now to make clear that whatever action toluylendiamine exercises on the blood cannot possibly be a direct one. Its destructive action is not like that of glycerine or distilled water—which destroy at once the red corpuscles with which they are brought into contact. Their injection into the blood is followed almost immediately by hæmoglobinuria; the degree of destruction is directly proportional to the quantity injected, and is greatest at the time of injection. Their action on the blood corpuscles within the circulation is precisely the same as it is on them outside the body, and ceases when they pass out of the blood.

Very different is the case with toluylendiamine. It does not destroy the blood directly; in rabbits its injection is not followed either immediately or remotely by hæmoglobinuria; its destructive action is not proportional to the quantity injected, for we have seen that it may be great with a small dose (when the spleen is present) and absent altogether with a large dose (when the spleen is absent); nor does it reach its greatest intensity at the time of injection, but not till several hours later—at a time when, as I have shown, less than a milligramme, if even so much, is present in the blood. Lastly, its action on the corpuscles of the blood is not the same as its action on them outside the body. For while within the body, as we have seen, it gives rise to well-marked changes in the plasma and corpuscles—formation of granules, spherules, stromata and *Schatten*—at a time, too, when hardly a milligramme is to be found in the whole blood—outside the body I have found that its addition to normal saline solution in proportions so great as  $\frac{1}{4}$ ,  $\frac{1}{2}$  and 1 per cent. greatly increases the preserving power of the latter on red corpuscles. In all these respects, then, the destructive action of toluylendiamine presents a striking contrast to that of such agents as glycerine or distilled water. It is apparently as indirect as that of the latter is direct.

And in this respect, although to a less marked degree, a similar contrast is presented by the actions of toluylendiamine and pyrogallic acid. As I have already described, after the injection of pyrogallic acid into the blood large numbers of red corpuscles are injured so directly by contact with the substance that within fifteen minutes they are to be found enclosed within the cells of the spleen. No such direct poisonous action on the red corpuscles was ever observed with toluylendiamine. The destructive action of pyrogallic acid on the blood is thus, to a considerable extent at least, a direct one.

Interesting confirmation of the distinction I have thus drawn between the action of different poisons on the blood was afforded me by experiments, in which I excised the spleen and then injected pyrogallic acid. The result showed that the action of poisons that act directly on the blood is little or not at all affected by removal of the spleen.

*Experiment 78.*—Normal rabbit; 0.5 gramme of pyrogallic acid per kilo injected intravenously. The following day *Schatten* found in the blood. Two days later the animal looking ill; number of red corpuscles fallen to 3,410,000 per cubic millimetre. From this time gradual recovery.

*Experiment 79.*—Rabbit; spleen excised; 0.55 gramme of pyrogallic acid per kilo injected intravenously. Following two days numerous *Schatten* in blood, and on the third day the number of red corpuscles had fallen to 1,360,000 per cubic millimetre. From this time onward the recovery was rapid.

In this case the removal of the spleen was absolutely without effect on the destructive action of pyrogallic acid. When smaller doses were given, some slight difference was observable in the direction of a lessened effect after removal of the spleen, but this was in no sense so marked as we saw to be the case with toluylendiamine (Experiments 75 and 76). The removal of the spleen slightly lessened the destructive action, but it failed to do what was so striking in the case of toluylendiamine—abolish it altogether. This result need not occasion any surprise. On the contrary, had it been otherwise—had the removal of the spleen influenced to any material extent the action of a substance so undoubtedly injurious to the blood as pyrogallic acid, one might have felt disposed to think that some fallacy underlay the observations

already recorded regarding its effect on the action of toluylendiamine.

As it is, the result serves, in my opinion, to establish two things: first, the difference between the action of substances that act directly on the blood and those that act indirectly; and secondly, the importance of the spleen in determining the action of the latter. The importance of this latter conclusion becomes evident when it is stated that according to my observations hæmolytic action in health is of this indirect nature.

Since, then, the action of toluylendiamine differs in so many respects from that of agents acting directly on the blood, since, in particular, unlike the latter, its destructive action can be lessened or abolished altogether by the removal of a richly cellular organ, the spleen, I conclude that it is the activity of cells more than anything else that in its case determines the occurrence of hæmolytic action. This conclusion is, of course, only applicable in its entirety, so far as toluylendiamine is concerned, to the particular animal on which the observations have been made. Its importance, however, is much more wide-reaching, and rests on the circumstance that it is, I think, capable of extension to all other animals and to the particular poisons that in their case, like toluylendiamine in rabbits, act indirectly on the blood. For inasmuch as I have shown that the cells are the final arbiters whether or not a substance of this kind shall occasion hæmolytic action, the conclusion is obviously one of wider applicability than usual. The issue is left with the cell—a factor common to all animals alike; and in this particular case, not with cells generally but with the cells of spleen and of the gastro-intestinal capillary area.

#### HÆMOLYSIS IN HEALTH.

I think it is possible, in the light of the foregoing observations, to form a somewhat clearer conception of the process of hæmolytic action in health than has hitherto been possible. We have seen, in the case of a body so stable as toluylendiamine, how much its hæmolytic action is dependent on the activity of a particular group of cells. I think it is permissible to conclude that the same thing will apply—if possible even more—to the comparatively harmless products formed in health likely at all to affect the blood injuriously. Under no circumstances, I conceive, are the ordinary products of metabolism of such a character or in such amount as to exert a direct injurious action on the blood. So far as they act in this way their action is an indirect one, and as such will specially depend on the activity of the cells of the spleen and the gastro-intestinal capillary area. We possess as yet no data for estimating the amount of hæmolytic action in health. I conclude that it is considerable, although there is no reason to consider it great. It varies very considerably not only in different classes of animals, but also in different animals of the same class and even in the same individual at different times. It has a certain relation to the general bodily activity, being greatest in youth and early adult life and becoming less as age advances. This relationship, however, is not so much in virtue of bodily vigour *per se* as of the activity of one of the processes usually associated with bodily vigour—namely, digestion. I conclude that if it were not for the changes in the blood associated with digestion the daily hæmolytic action would be almost *une quantité négligable*, instead of being, as I conceive it is, considerable in its amount and still more in its importance. The change which would then occur would be of the nature of a slow decay and would be evidenced in the case of the red corpuscle by its death without disintegration and by the presence of large heaps of blood pigment in the spleen and liver capillaries. This, however, as we have seen, is not the case; and the difference is mainly to be ascribed to what takes place during digestion. The activity of the cells lying in closest relation to the blood, especially those of the gastro-intestinal capillary area and spleen, affects in the first instance the plasma, and secondarily such of the red corpuscles as are already weakened, and brings about their disintegration. We have seen what the fate of the hæmoglobin under such circumstances is—namely, that it is liable to be carried to the liver and be there broken up into bile pigments, leaving, it may be, not a trace of blood pigment behind.

I conclude, however, that all the hæmoglobin thus set free need not thus be disposed of. To what extent the presence of a certain amount of iron may be necessary for the liver cell to carry out its various functions it is, of course, impossible to say. So far as my observations go I am disposed to think that once it has passed into the liver cell the iron of the hæmoglobin molecule is less available for subsequent use than it is when stored up either in spleen or bone

marrow—use, that is to say, for purposes of blood formation. It is this consideration that leads me to think that a considerable part of the hæmoglobin set free during digestion is in all probability utilised at once for purposes of blood formation, without being converted either into bile pigment or blood pigment. For it will not have escaped your attention that the areas which I have described as the seats of hæmolytic action—the gastro-intestinal capillary area, the spleen and the bone marrow—are precisely the areas in which blood formation is supposed to go on. That both processes should go on in one and the same place involves no contradiction. It is, on the contrary, what one would expect if, as I believe is the case, the blood is a tissue, and, like other tissues, is under the control of one particular set of cells. The same law holds good for it as for other tissues. It is the wear and tear on the blacksmith's muscle that leads to its great development; so also I conclude, in the case of the blood in health,—blood formation and blood destruction go hand in hand, take place in the same areas and are affected by the same conditions. It might be interesting to speculate why this reconstruction should be constantly taking place. This would, however, lead too far from my present purpose, which is to direct attention to the important fact that such is the case.

As to the extent to which hæmolytic action occurs in health, it is not necessary to consider it great in order to prove it important. For like many other normal processes, it derives its chief importance from the variations that occur in disease. I conclude the amount of hæmolytic action which daily occurs is strictly determined by the degree of activity of the leucocytes of the blood and the mass of lymphoid cells in the spleen and gastro-intestinal tract.

#### *Influence of Digestion.*

As far as the activity of these cells is influenced by the character and amount of the food taken, precisely to the same extent is hæmolytic action affected. It is greatest, therefore, I conclude during full digestion, and is reduced to a minimum during starvation. As evidence of this I note amongst other facts the following: 1. During full digestion I find changes in the plasma and red corpuscles within the spleen identical in character with those produced by the action of destructive agents and far in excess of anything ever found in the starving animal. 2. For the reasons fully stated in my first lecture the increased formation of bile pigments during active digestion is evidence of an acute hæmolytic action at this period. 3. The large increase in the number of leucocytes within the blood during digestion as noted by Pohl, and especially within the portal blood as noted by myself, taken along with the corresponding increased formation and excretion of uric acid at this period as noted by Horbaczewski, appear to me to be facts of special interest in this relation—the former indicating the increased activity of leucocytes at this period and the latter the increased disintegration that is occurring both in them and in the cells of the spleen. 4. The increased tendency to coagulation at this period, specially marked in the portal blood first described by Wooldridge and since confirmed by Wright, is important as indicating at once the activity and instability of all the elements of the blood at this period—viz., of plasma, leucocytes and red corpuscles. 5. Lastly, as marking the special activity of the spleen during this period, I would note the great enlargement which according to observations I have made on animals takes place in the spleen during digestion. Still more markedly is this the case under the influence of hæmolytic agents injected directly into the blood. The action of such agents on the spleen in causing enlargement is, I have found, both immediate and striking. The spleen within less than half a minute after their injection becomes enlarged several fold and engorged with dark venous blood, where previously it had been small, comparatively poor in blood and of a bright red colour. The action is a direct one on the tissue of the spleen itself. Great variations in size may occur for a time under the influence of such substances—the spleen contracting up and again expanding at very frequent intervals. With very large doses the usual effect may be reversed, and instead of expansion we have sharp contraction, lasting it may be for several hours. Such a contraction I have found sometimes take place immediately after death; a fact of some importance, since it indicates that the activity of the spleen during life cannot necessarily be gauged by its size after death.

#### *Action of Cholagogues.*

Within the limits of health, next to digestion the greatest

hæmolytic takes place, I conclude, under the action of chologogue agents, such as mercury, podophyllin, iridin, euonymin &c., action of which has been so carefully studied by Professor Rutherford. The action of these "hepatic stimulants" is chiefly evidenced by an increased excretion of bile and increased formation of bile pigments. They are hence spoken of as stimulants of bile secretion, and credited accordingly with a special stimulating action on the liver. The foregoing observations show how such an increased formation of bile pigments must necessarily have been preceded by an increased destruction of blood. On the view hitherto prevalent that the liver has as much to do with this destruction of blood as with the subsequent excretion of bile and bile pigments, it was natural to ascribe the action of such substances to their special action on the liver. Since, however, according to my observations the destruction of blood occurs chiefly outside the liver, and is effected mainly by the activity of cells of the spleen and gastro-intestinal mucosa, I conclude that the chief and certainly the initial action of chologogue agents is not on the liver, as hitherto supposed, but on the cells outside the liver, by whose activity the preceding hæmolytic is determined. In the case of chologogues, as in that of hæmolytic generally, the chief function performed by the liver is to excrete the products already formed. This view by no means excludes the one that these substances also influence the activity of the liver cells; on the contrary, such is doubtless the case. What I conclude, however, from the observations now recorded is that such an action on the liver cell does not account for everything; but that, to be effective at all, these agents must have first acted on the blood through the lymphoid cells of the spleen and gastro-intestinal mucosa.

#### HÆMOLYSIS IN DISEASE.

In disease, as in health, hæmolytic is also of this indirect nature. It is not induced by substances having a direct injurious action on the blood. The exceptions to this rule are such affections as paroxysmal hæmoglobinuria and the hæmoglobinuria of burns and scalds and similar diseases, where the destruction is, as I have elsewhere shown, induced outside the area of the portal circulation, by influences—e.g., exposure to cold or great heat—acting, it may be, over only a limited area. Malaria also exemplifies a disease in which hæmolytic is induced more or less directly,—in its case, by the parasitic action of the plasmodia of malaria on the red corpuscles.

The type of increased hæmolytic of most importance and interest in disease, however, is not that attended by hæmoglobinuria, but that marked by progressive deterioration of the blood and profound anemia unaccompanied by any such direct evidence of destruction as hæmoglobinuria. Such a disease I have elsewhere, by a lengthy series of observations, shown pernicious anemia to be. The excessive hæmolytic which occurs in it, evidenced amongst other things by the large accumulation of pigment in the liver, exemplifies, as I have inferred, the action of a poison or poisons of a specific nature produced by agencies acting within the gastro-intestinal area. In respect of its character and its evidences—the changes presented by liver and spleen, the absence of hæmoglobinuria and nevertheless the presence of blood pigment and of iron in the urine, the occasional occurrence of jaundice—the hæmolytic of this disease is typically that induced by substances acting indirectly on the blood. So also, I conclude, is the excessive hæmolytic which marks the whole series of toxæmic conditions of which jaundice is a more or less prominent feature, especially of the worst form of all, that condition termed acute yellow atrophy of the liver.

**PUBLIC LAVATORIES AT REDCAR.**—The question as to whether the erection of public lavatories was advisable seems to have created considerable dissension in the minds of the town councillors of Redcar. It would have been thought that on such a subject unanimity was inevitable. Common sense however prevailed, and in the end a committee was appointed to choose a site and provide an estimate of the expense of the undertaking.

**GUEST HOSPITAL.**—By the statement of the honorary secretary, read at the annual meeting of the subscribers to this charity, which was held on the 12th inst., a satisfactory record was offered. One item of the report was specially cheering—viz., that the contributions of workmen had reached a higher level than they had ever attained previously. More funds, however, were required to provide additional accommodation for private patients.

## AN ANALYSIS OF TEN THOUSAND CASES OF DISEASE OR DISTURBANCE OF THE EYES, SEEN IN PRIVATE PRACTICE:

WITH NOTES AND COMMENTS.

By R. BRUDENELL CARTER, F.R.C.S. ENG.,  
OPHTHALMIC SURGEON TO ST. GEORGE'S HOSPITAL.

(Continued from p. 391.)

#### AFFECTIONS OF THE CORNEA.

THE total number of affections of the cornea amounted to 492, of which 227 were in males and 265 in females. The cases were as follows:—

	Males.	Females.	Total.
Superficial keratitis . . . . .	38	53	91
Interstitial keratitis . . . . .	31	61	92
Superficial ulceration . . . . .	56	52	108
Deep ulceration . . . . .	60	68	128
Abrasions or slight injuries . . . . .	20	9	29
Severe wounds . . . . .	7	1	8
Conicity . . . . .	5	15	20
Staphylocoma after sloughing . . . . .	4	5	9
Cicatrices after operation . . . . .	0	1	1
Pemphigus . . . . .	2	0	2
Congenital malformation . . . . .	1	0	1
Kerato-iritis (rheumatic) . . . . .	0	1	1
Kerato-iritis (in leprosy) . . . . .	2	0	2
Lead deposit . . . . .	1	1	2
	227	265	492

The chief facts brought into prominence by the foregoing table are the greater liability of the female sex to suffer from keratitis, both superficial and interstitial, as well as from conicity; and the greater liability of the male sex—as might be expected from the conditions of their lives—to wounds and injuries, both trivial and severe. It is also remarkable, as illustrating one of the differences between hospital and private practice, in that no cases of the severe "vascular keratitis" with which we are so familiar in the former are included. I have purposely omitted the figures relating to the form of keratitis which is associated with the so-called "serous" iritis of modern German writers—the "aquo-capsulitis" of fifty years ago,—because it seemed more convenient to regard the affection of the cornea as secondary to, or a complication of, the affection of the iris and uveal tract. I have placed these cases under "iritis," but the tissues involved are really so numerous that the disease almost deserves a separate place in classification.

**Superficial keratitis.**—In the 38 males who were the subjects of superficial keratitis the right eye alone was affected in 13, the left eye alone in 14, and both eyes in 11. In the 53 females the right eye alone was affected in 13, the left eye alone in 24, and both eyes in 16. In 5 males and 4 females the eyes were of myopic formation, and in 2 males and 3 females they were hypermetropic. Wherever such errors of refraction were found to exist they were carefully corrected by glasses at an early period after recovery and before the patients were allowed to resume work. As a rule, the cases were not severe when seen at an early stage and if they had not been irritated by improper local applications. The treatment usually consisted in the instillation of a solution containing atropine and cocaine, perhaps a grain of the former and four of the latter to an ounce of water, three or four times a day, followed after a few days by a very weak ointment of the yellow oxide of mercury. If only one eye were affected, or if one were much worse than its fellow, it was closed by a vertical strip of gelatole plaster, so applied as to fasten down the cilia of the upper lid to the cheek and to arrest all friction movement. The general health was carefully considered, the diet regulated, the patients kept in a dimly lighted room when in-doors, but encouraged to be out as much as possible, with the protection of dark spectacles or even of opaque pads. Great care was taken to avoid everything which could either excite or aggravate photophobia, because the nervous conditions on which this depends, and the spasm of the orbicularis muscle which it excites, are alike very unfavourable to recovery. As soon as photophobia is at all confirmed my experience is that it maintains a morbid condition in spite of remedies and that it requires the prompt attention of the surgeon. I am accustomed in such cases to divide the orbicularis muscle at the outer canthus, using an anæsthetic if necessary, and making a clean cut through all the tissues, conjunctiva, skin and muscle, from the outer

canthus quite up to the margin of the orbit. The incision is best made by a sharp curved bistoury, the point of which should be carried within the conjunctival sac, made to transfix all the tissues, and then to divide them in a horizontal line continuous with that of the palpebral fissure. The cut will bleed freely for a minute, but the bleeding soon stops, and the patient should be put to bed in a dark room. The relief afforded to the eye by the removal of spasmodic lid pressure will be immediate and the photophobia, as a rule, will speedily disappear. If any one medicine be of greater value than another, for the purpose of diminishing corneal irritability, it is arsenic, and this I have always given in the absence of any other special indication, or when any such indication had been fulfilled. If the keratitis were still obstinate, in spite of muscular section and treatment, I have had recourse, with great advantage, to peritomy, or the removal of the circum-corneal annulus of the conjunctiva and subconjunctival tissue. The results of this operation are often long in declaring themselves, but they are of the most satisfactory description when obtained.

As illustrations of some of the more severe and obstinate cases I may quote the following:—

Miss C—, aged twenty, was brought to me in the month of April, suffering from chronic superficial inflammation of both cornea, which had existed for seventeen months with but little alteration. There was much photophobia, but there were no serious changes in the corneal tissue, the epithelium being chiefly affected. She brought with her a bundle of prescriptions, from which I made out an account of the treatment to which she had been subjected. This included a lotion with quinine and alum, the insufflation of dry calomel, a zinc lotion, a borax lotion, atropine drops, syrup of iodide of iron internally, a belladonna lotion with ointment of peroxide of mercury, quinine and anodynes internally, blisters, alum lotion, opium lotion, atropine drops with bromide of potassium internally, drops of iodide of potassium, tincture of serpentaria and chloral hydrate, and lastly iodine paint. I divided both her orbicularis muscles and put her upon arsenic, with a very weak ointment of yellow oxide of mercury as a local application, and in three or four weeks she was quite well.

Miss L—, aged twenty-seven, was seen in the month of January, after she had suffered from keratitis of the left eye for fifteen months. The lids were swollen, there was intense photophobia, and the skin of the cheek was much irritated by the overflow of tears. She had been continuously under medical care and had never derived benefit. I gave her boric-acid ointment for the cheek and for a chink or crack which the photophobia had produced at the outer canthus, and a 10 per cent. solution of cocaine as a local application to the eye. There was no improvement, and the eye was then closed and arsenic administered, but with no better results. At last, but not until March, I prevailed upon her to submit to what she called an operation, and performed peritomy, at the same time dividing the orbicularis. All active symptoms rapidly disappeared and the cornea ultimately regained its transparency, which was the more important inasmuch as the other eye, which escaped inflammation, was the subject of laminar cataract.

Miss M—, a lady of middle age, was the subject of very obstinate superficial keratitis with very general opacity. When somewhat better she went to Yorkshire, and there, having a relapse, she came under the care of Mr. Teale, who, finding that she made no satisfactory progress, performed peritomy. The operation at once arrested the further progress of the disease, and the cornea almost entirely recovered its transparency in the course of a few months.

Miss H—, aged fourteen, was attacked by keratitis, at first of one eye only, and was seen by a practitioner who gave her a sulphate of zinc lotion. This at once greatly aggravated the disease and the other eye soon afterwards suffered. The child ultimately made a complete recovery; but the irritant stirred up mischief which at one time threatened to be very serious, and a malady which would have been trivial if treated at first in a soothing manner was converted into one which interrupted the education of the patient for at least six months.

Among cases of an unusual character I may mention one in which keratitis existed over a symmetrical annulus of each cornea, leaving the centre free; and another in a medical man, whose right cornea became inflamed after the removal of a Meibomian tumour from his upper lid. I did not see him during the acute period, but the inflammation had left an indelible mark in the shape of a central nebula, and the eye was astigmatic, a condition which the patient

assured me had been produced by the disease, and which he attributed to a modification of the corneal curvature during its course. He stated quite positively that he had normal vision of the affected eye until it became inflamed, and as it was the right one he was likely to know.

Another case worth mentioning was one in which a gentleman had suffered from keratitis for six weeks, under the care of an eminent ophthalmic surgeon, to whom a second was in course of time added in consultation, because the general practitioner in attendance discovered what he believed to be a foreign body imbedded in the cornea. The original consultant differed from this opinion, and the second consultant agreed with it, with the result that I was invited to confer with them. A very careful examination by focal illumination and other methods showed a sort of double black speck with a connecting line, like a dumb-bell, with one end larger than the other, which seemed to lie obliquely in the corneal tissue below the pupil, and in an approximately horizontal position, the larger end nearer the surface. There was no trace of corneal wound, but much general disturbance of the surface epithelium—disturbance which was said to be diminishing and the sight to be improving. I formed the opinion that the dark object was a mass of pigmented cell proliferation and not a foreign body in the ordinary sense, and therefore opposed a suggested exploratory puncture. The dark object ultimately underwent absorption and the case terminated in recovery.

*Interstitial keratitis.*—In the 31 males who suffered from interstitial keratitis the right eye alone was affected in 2, the left eye alone in 5, and both in the remaining 24. In the 61 females the right eye alone was affected in 8, the left eye alone in 12, and both in the remaining 41. The figures, as far as they have any significance, may be taken to illustrate the distinctly constitutional character of the affection, the greater liability of the female sex, and the greater liability of the left eye. In 5 males and 6 females the eyes were recorded to have been myopic; in 6 males and 10 females they were hypermetropic, but it is of course possible that the nature of the disease may in some instances have stood in the way of any accurate measurement of the refraction. That this was so is rendered probable by the percentages, which on the 92 cases in both sexes would give 12 per cent. of myopes and 17 per cent. of hypermetropes, as against a general average of 31.5 per cent. of the former and 23.23 per cent. of the latter.

In many of the cases the evidences of inherited syphilis were unquestionable, but in several, and those not the least severe, such evidences were wholly wanting. In none of the latter, moreover, have I had any reason to suspect the implantation of syphilis by vaccination—an occurrence to which I believe I traced interstitial keratitis many years ago in a child whose parents were unquestionably free from taint. But the cases in which syphilis was clearly present and those in which it might be assumed to be absent were so precisely alike in the general character of the eye affection that I have regarded the latter as being identical with the former, and have believed with regard to all of them that the specific poison must have found entrance by some unusual channel. The principles of treatment have been always the same—namely, to sustain the general health as much as possible; to administer mercury internally, in small doses and for a long period; to use none but the most soothing local applications; and, when only one eye was affected, to give the most complete attainable rest to the other. The worst cases which I have seen, and those in which some permanent injury has been inflicted upon the cornea, have been those in which, at some early period, applications of an irritating character have been employed, such as solutions of zinc sulphate or of silver nitrate; and the mischief done in this way is often irremediable. In any protracted case severe photophobia is a common symptom and is one which is liable to recur from time to time. It should on each occasion be met at the very commencement by confinement to a dimly lighted but well-ventilated room; but this confinement should never be permitted to interfere with bodily exercise, which may be accomplished, even in the dark, by dumb-bells or similar contrivances, or by skipping. A first return to daylight, as the photophobia subsides, may often be facilitated by the use of spectacles filled with glass of a peacock-blue tint, which, when tested by the spectroscope, is found wholly to exclude the red rays of the spectrum. In every specially bad case I have been accustomed to perform iridectomy, always with great benefit; and I have seen many instances in which I have done this to one eye only, it being the

more severely affected of the two, with the result that it has made by far the best and most complete recovery. The following may be taken as examples of the more severe forms of the affection:—

Miss W—, seen once in consultation when nine years of age, with photophobia and corneal irritation of the right eye. This soon subsided, but two years later she was brought to me again with very severe interstitial keratitis of the right eye and a commencement of similar trouble in the left. The right eye was at once iridectomised and both ultimately recovered; but the right cornea regained its transparency much more completely than the left, and the right is now the working eye for most purposes.

Mr. W—, seen at ten years of age, with very severe double interstitial keratitis, to which drops containing nitrate of silver had been applied. Both eyes were iridectomised soon afterwards and both recovered, but with some permanent residual haze. Four or five years after the operations there was myopia = 5 D., with corrected vision =  $\frac{1}{2}$ .

Miss B—, very severe case, affecting the left eye only. Iridectomy, followed a few weeks later by peritomy. Ultimate complete recovery.

Miss D—, aged twenty-four. Tall and well-grown young lady, of perfectly healthy general aspect, but with history of paternal syphilis. Both eyes had been severely affected in childhood and both ears. She was deaf, and the corneae were so hazy that she was unable to read. There were clear patches among the haze, and I made two very small iridectomies, in the hope of improving vision, but with very little success. In such cases, even when an artificial pupil can be made behind a comparatively clear portion of cornea, the result is usually disappointing, although the operation is worth trying. Even if the rays which enter through the artificial pupil form a defined image upon the retina, that image is generally damped and rendered indistinct by the diffused light which falls upon it through the corneal haze.

Mr. Y—, aged sixty. Case similar to the preceding. On account of the cloudiness of his corneae an artificial pupil had been made in one eye by the late Sir William Bowman and in the other by the late Mr. Critchett, but his sight had remained exceedingly defective. He came to me on account of progressive cataract and I removed his lenses, but the state of the corneae remained as an insurmountable impediment to good vision.

Miss P—, aged seventeen. Severe case affecting the right eye only, and already beginning to improve, as far as the acuteness of the inflammation was concerned, but with the cornea densely clouded. Peritomy was performed and was followed, after the lapse of a few weeks, by steady and continuous improvement.

Mr. H—, aged twenty-two. Specific paternal history. Both eyes were severely affected, and both had been injured by irritating applications. I saw him in consultation with a provincial ophthalmic surgeon, and he has steadily improved under a treatment by closed lids and the internal administration of mercury.

*Superficial ulceration.*—The cases of superficial ulceration of the cornea were 108 in number—56 in males and 52 in females. In 13 males and in 13 females the right eye only was affected; in 23 males and 9 females the left eye only; and both eyes in 20 males and in 30 females—figures which can scarcely be regarded as other than accidental. The great majority of the cases were phlyctenulae, or ulcerating corneal pimples, occurring in delicate children, and readily yielding to constitutional treatment combined with ointment of yellow oxide of mercury as a local application. There were some, however, of a totally different and very remarkable type, which seemed to point to some underlying neurosis, some definite failure or perversion of the nervous influence by which the nutrition of the parts concerned is normally controlled; and the changes thereon consequent have extended to other tissues of the eye, so as to destroy or materially to impair the sight.

Mr. D—, a gentleman between forty and fifty years of age, was brought to me on account of corneal ulceration. He was somewhat prone to liver derangement, had a flushed face and congested conjunctivae, and his forehead presented numerous pimples of acne. Both corneae were scarred by small nebulae, the surfaces of which were more or less flattened, and near the upper portion of the right cornea there were two small clear ulcers, looking almost as if little bits of corneal tissue had been gouged out, and each with a vessel running to it from the conjunctiva. Under the influence of mercurial alteratives and salines, with yellow ointment to

the eyes, he soon improved, but the improvement was not of long duration. When he ceased to be under treatment fresh ulcers appeared, and after a while he became the subject of an insidious iritis, which formed small adhesions in each eye. Then his lenses became opaque and were extracted—the right without complication, the left, some months afterwards, with a small loss of vitreous, but with good healing and fair vision. He had scarcely recovered from the second extraction when his right cornea again became the seat of ulceration, and the consequent nebulae and facets so much impaired his sight as to leave him unable to read small print. At the same time very delicate deep films appeared in both eyes, apparently from cell proliferation on the posterior capsule, and these films, when torn by needles, did not retract, but fell together again, leaving matters much as before. The patient can see his way about and can read large print, but his eyes are only of very moderate usefulness, and the persistence of one morbid change after another is not of good omen for his future.

A still more distressing case was that of a young lady of twenty, who came to me asking me to remove her left eye, which, she said, had never possessed useful sight and had become a source of constant pain and trouble. I found great congestion and hypertrophy of the conjunctiva and retro-tarsal folds, and the upper part of the cornea, down to below the level of the pupil, was thickened, vascular, superficially ulcerated and very painful. The lower part was of normal aspect and so, as far as could be seen, was the iris. The patient was very thin, somewhat anæmic, and the subject of extremely obstinate constipation, but seemed otherwise healthy, and was possessed of great energy and decision of character. After trying for a month without success to improve the condition of the eye by treatment I consented to sacrifice it, being very much influenced by the consideration that it had never been useful. For the sake of appearances I performed Mules's operation, on May 5th, with entire success. There was rather more swelling of the lids than usual, but the healing was complete and the stump left nothing to be desired, nor has it ever since given the slightest trouble. An artificial eye was worn with perfect movement and all seemed to be satisfactory, and so remained for some months. In the following October, however, the right cornea was attacked in the same way that the left had been in the original affection. The patient improved under treatment, relapsed, improved again, and again relapsed, vision not being affected except by the state of the cornea, which varied from time to time. During many months these fluctuations continued, the patient being all the time under my observation or under that of Mr. Teale of Leeds. At last, after a consultation with him, I scraped away all the diseased corneal tissue, irrigated the surface with boro-glyceride solution, covered it with iodoform, and closed the lids with pad, plaster and bandage, which remained undisturbed for a fortnight. At the end of that time the eye seemed well, the scraped portion of cornea being covered by a firm cicatrix and the rest being clear and bright, with good vision. As a measure of precaution the coverings were reapplied for another fortnight, and then the eye was used. All went well for a few weeks, when the cicatrix yielded and the disease broke out afresh. I proposed to renew the scraping, but a day or two intervened before this could be done, and by that time the mischief had spread over the whole of the corneal surface. In the hope of saving at least a portion of the margin, behind which an artificial pupil might eventually be made, I repeated the scraping and disinfection, and pared and united the edges of the lids. There was no reaction, and all pain soon disappeared. After the lapse of some months, the eye being quite comfortable, I thought of reopening the lids, but on examination it appeared that perception of light had wholly disappeared. The patient was unconscious even of bright sunlight directed upon the surface of the upper lid by a lens, and this state seemed to show that disease must have invaded the retina as well as the cornea. She had become active and helpful as a blind person, and was unwilling to submit to any further treatment. Neither Mr. Teale nor myself could recall any precisely similar case; but I have since heard of an almost identical one from Mr. Bickerton of Liverpool. It seems impossible to explain so remarkable a succession of morbid changes in any other way than by the hypothesis of profound neurotic disturbance.

*Deep ulceration.*—The cases of deep ulceration of the cornea numbered 126—60 in males and 66 in females. As might be expected, the cases in which both eyes were thus

affected were comparatively rare, and included only 1 male and 10 females. It may be presumed that the difference would be due to the greater number of traumatic cases in the male sex. The right eye was affected in 30 males and 31 females, the left in 29 males and 25 females. Putting aside cases arising from injury (and a comparatively slight injury to the cornea is often followed by deep ulceration in the aged), the most noteworthy have depended upon conditions implying exhaustion, and have reminded me of the dogs which were either starved or fed upon isinglass and water by Majendie, and whose corneæ sloughed in the centre. One such instance was furnished by an Indian chaplain who had been reduced almost to a skeleton by chronic dysentery; another by a lady who had suffered from "bleeding piles," and had recently been operated upon for their relief. The ulcers of inanition are of two distinct kinds: the one central, which is the more common, the other peripheral, cutting out a deep groove around the corneal margin and threatening, so to speak, to trephine it. The central ulcer usually presents a grey and irregular sloughing surface; the peripheral ulcer is often so transparent that it might easily escape detection by a hasty observer.

A sloughing ulcer which occupies the central portion of the cornea must leave behind, in the best result, a dense central opacity which will cover the pupil and take away the power of sight; and experience shows that any such ulcer which is rebellious to treatment will nevertheless heal spontaneously as soon as it has perforated. The effect of perforation is to diminish tension, and the same thing may be done by iridectomy. For any central sloughing ulcer, which deepens or extends in spite of treatment, it has therefore been my practice to perform iridectomy promptly, selecting for the purpose the locality in which the artificial pupil, which must in any case be needed to restore vision, seems likely to be most useful. The older the patient, apart from extreme decrepitude, the more desirable will it usually be to lose no time; but the measures which may be taken previously, and which may sometimes supersede the necessity of an operation, are to increase and support the strength by suitable diet and medicines, and to apply solutions of eserine to the eye, at the same time maintaining closure of the lids by plaster. In some cases I have found it useful to scrape and irrigate the ulcer as a preliminary to lid closure, but this chiefly in comparatively young subjects. Eserine appears to exert a decidedly controlling influence over the migration of white corpuscles, and through this influence to arrest the spreading of an ulcer. When, as usually happens, there is much pain, the eserine may be combined with cocaine, without any diminution of its special effect. The peripheral ulcer does not leave a cicatrix which interferes with vision, and it may generally be cured by bodily rest, with generous diet and closure of the lids, aided, when healing commences, by the occasional application of a morsel of yellow ointment.

*Abrasions or slight injuries* of the cornea were 29 in number—20 in males and 9 in females. In two males both eyes were affected, the cases being both due to gunpowder explosions. In 13 males and 5 females the right eye suffered; in 5 males and 4 females the left. Many of the cases were due to the lodgment of foreign bodies, the presence of which had often escaped observation, even although the patients had been under medical care. I have notes of two cases in which a foreign body had remained undetected in the cornea for three weeks, one in which it had so remained for six weeks, one for seven weeks, and one for three months. Among curiosities of practice I may mention the case of a young lady who burnt the cornea of her left eye with hot curling tongs, and that of a gentleman who came to me one morning saying that he had been struck by something on the eye while shooting in Scotland on the previous day, and that he had not only lost the sight of the injured eye, but that its altered appearance showed it to have sustained grievous injury. He had travelled all night in order to seek advice. He had been struck by a flake of burning cigarette paper, which was instantly quenched by the moisture of his eye, and adhered closely to its surface, covering most of his cornea and some of the conjunctiva with a black patch. I peeled off the bit of paper with forceps and had the satisfaction of finding the eye unhurt. A few drops of cocaine solution removed all discomfort, and the patient returned the same night to his grouse moor.

*Severe wounds* of the cornea numbered 8—7 in men and 1 in a woman. In six of the men the right cornea was wounded; in one man and in the woman the left. The cases were only dis-

tinguished from other severe injuries by the limitation of the external wound to the cornea, and will be more appropriately mentioned when such injuries come under consideration. An exception may be made in the case of a lad of fourteen, who pierced his right eye with a sharp steel pen containing ink. The pen passed rather deeply between the layers of the cornea without penetrating into the anterior chamber, and left an ink-stained triangle conspicuous against a blue iris. Sharp inflammatory reaction seemed impending; but the local application of atropine and cocaine, with cold moist compresses, complete functional rest, a dimly lighted room and a saline purgative, brought about a better state of things, and the boy recovered without any impairment of sight. The ink stain was visible for some time, but underwent gradual absorption.

*Conicity* of the cornea occurred in 20 cases—5 males and 15 females. In the males the right eye alone was affected in two; both eyes in the other three. In the females the right eye alone was affected in one, the left eye alone in two, and both eyes were affected in the remaining twelve.

Some of my contemporaries will possibly remember that forty-five or more years ago a surgeon (whose name I am glad to have forgotten) advocated what he called the "emetopurgative" treatment of conical cornea. This treatment consisted in administering to the hapless patient an emetic and a purgative every morning for a twelvemonth. One can only feel surprise at its having failed to cure, together with conical cornea, every other ill to which human flesh is heir. But it was actually practised, and, if my memory does not deceive me, a controversy of a somewhat acrimonious character was occasioned by the respective claims of two practitioners to the honour of having devised it. It is at least certain that during its prevalence—and in the absence, it must be remembered, of the exact methods of testing vision which have been employed in more recent times—persons were found who maintained that they had derived benefit from it. I mention it only because one of my male cases of conical cornea occurred in the person of a decrepit-looking and emaciated elderly gentleman, who asked me if I had ever heard of the plan in question, and who went on to say that he had survived its adoption. It had done no good to his eyes, and had, he declared, completely shattered his constitution.

Knowing, as we now do, that conicity is a consequence of central atrophy of the cornea, the thinned portion being projected forwards under the influence of intra-ocular pressure and of the action of the recti muscles, I think it is usually vain to treat it, as I have seen done, as if it were progressive myopia, requiring the strict enforcement of functional rest. The remedy, complete disuse of the eyes, would for many persons be worse than the disease. My own experience convinces me that it is desirable to operate for the cure of conicity in all ordinary cases—certainly in all in which the affection is progressive and in which the condition of the general health is not such as to place any difficulty in the way. After trial of various methods in hospital as well as in private practice I have finally settled upon the following plan. The eye being first completely cocaineised and the pupil brought fully under atropine, I set one of Bowman's corneal trephines to such a depth that it will not be likely to go through the membrane, and with it cut out a circle of tissue over the apex of the cone, of a size corresponding to the amount of projection. The circle of corneal tissue marked out by the incision is then peeled off by forceps, and the exposed surface touched with a very fine point of nitrate of silver. The touch should be a contact and no more, and solution of chloride of sodium should be applied immediately, or otherwise the effect of the caustic will be liable to spread beyond the borders of the wound and to invade the surrounding epithelium. The lids should then be closed with plaster and the patient kept very quiet in a dimly lighted room until all irritation has subsided. Atropine should be applied daily; the result will be a circular cicatrix on the apex of the cone, densely opaque and of a white or somewhat buff colour, which will effectually resist any further extension of the conicity, and will not permit any light to pass through it to the pupil. When this cicatrix is firmly established and all irritation has ceased, the pupil should be fully dilated and the fundus of the eye examined ophthalmoscopically by the direct method, in order to determine through what region of the cornea below the horizontal meridian and beyond the cicatrix the best curvature is maintained and the retinal vessels are visible with the weakest lens and with the smallest

amount of distortion. Behind the spot thus selected an artificial pupil is made by the method which I have described as "optical iridectomy," the essentials of such a pupil being that it shall be small, of V-shape, and that its base shall be at the pupillary margin and its apex towards the periphery of the iris. I need not republish here the technique of this operation; but I would not counsel anyone to undertake it until after a reasonable amount of dexterity in ophthalmic surgery and a fairly complete knowledge of the behaviour of the iris during evacuation of the aqueous humour have been gained as the result of practice. The operation is one which requires both skill and knack; but the visual results which it affords are worth all the care required in performing it. Finally, when the eye has forgotten the iridectomy, the cicatrix may be tattooed with India ink, and thus completely concealed from ordinary observation. To what extent the artificial pupil is noticeable will depend of course mainly upon the colour of the iris.

It seems to me to be of great importance that the order of procedure above set forth should be strictly adhered to. I have seen one case in which an eye was entirely lost in the hands of a surgeon who began his treatment by an iridectomy, and then, while the iris was still irritable, cauterised the corneal surface. Intense iritis was the result, and the eye was rendered permanently useless as an organ of vision.

*Pemphigus*.—Only two cases presented themselves of the peculiar gradual drying up of the cornea associated with complete conjunctival atrophy, which has been described in former years as "xeroma," and which has lately been regarded (I am not quite sure whether correctly) as a form of ocular pemphigus. Both patients were males, apparently in good health. Both were transferred to hospital, and there is nothing to record about them except that in one I tried the effect of dissecting off the atrophied conjunctiva and of replacing it by that of a rabbit. The graft united well and the progress of the corneal disease was stayed, but only for a time. As soon as the fresh conjunctiva came under the dominion of the patient's nutritive conditions it degenerated and shared the fate of his own which had preceded it. I could not claim more than that the advent of complete blindness had been delayed for a few weeks. The second case was only noteworthy as having afforded to the council of the Ophthalmological Society an opportunity of casting theegis of their protection over the practice of meeting homœopaths in consultation, and as having therefore compelled me, as a matter of ordinary self-respect, to withdraw from the membership of a body by which such a course was at least tacitly sanctioned.

*Lead deposit*.—I may pass over the single example of corneal malformation and the three instances in which keratitis was associated with rickets or with leprosy as being rare conditions of only small interest in daily practice, in order to mention the two examples of lead deposit on the cornea. Most text-books contain a word of warning against the use of lead lotions for the eyes, but they are nevertheless still occasionally prescribed. For simple conjunctivitis a solution of acetate of lead is probably quite as good as any other astringent, but it is apt to leave a scale of opaque carbonate upon any spot where the cornea has lost its epithelium. The late Mr. Dixon was accustomed to describe how an old lady, who had been cured of ocular catarrh by a lotion of acetate of lead, put the remainder of the medicament away in a cupboard, and brought it out as a precious treasure whenever there happened to be a bad eye in the family or among her neighbours. The bottle soon contained a considerable sediment of carbonate of lead, and this was carefully shaken up prior to application. In hospital practice it is not at all uncommon to see lead deposits upon the cornea, but private patients have generally been preserved from them. In one of my cases the lead had been on the cornea for about two years, and formed a dense white central patch, the surface of which was covered by little cracks, and which from time to time set up violent irritation by acting as a foreign body. The sufferer was a middle-aged man of very quiet temperament, and he had borne this long period of misery. About once a month his eye would be actively bad for a week, and then it would quiet down again, and be only uncomfortable. The patch so covered the centre of the cornea as to block out vision. After a thorough application of cocaine I scraped away the whole of the lead, the epithelium was soon reproduced and both vision and comfort were restored. In this instance, fortunately, the lead was external to the true corneal tissue, just beneath the epithelium, and it

had done no permanent injury. When it is deposited in an ulcer of any depth its removal is much more difficult and less favourable results must be looked for. The cicatrix will probably be at least partially opaque and the curvature of the cornea will be impaired. It is all the more necessary that such risks should not be incurred; and, as all the benefits to be obtained from a lead solution may be obtained equally from the salts of zinc or of silver, there is no excuse for subjecting a patient to risk of permanent injury in the course of endeavours to relieve a comparatively trivial affection.

(To be continued.)

## TREATMENT OF THE NOSE AND THROAT AS A SOURCE OF MIDDLE-EAR DISEASE:

PRECAUTIONARY SUGGESTIONS.

BY THOMAS BARR, M.D. GLAS.

THE extraordinary interest developed of late years in diseases of the nose and throat has led to the greatly extended use of remedies applied to those regions. Nasal irrigations, by means of the douche, syringe or simple sniffing, are not only much more frequently prescribed by medical men, but it is now no uncommon thing for patients to resort to them without medical advice or guidance. Cauterisation of the interior of the nose, by the galvanic cautery, chromic acid or other corrosive substance, has become almost the routine practice of the numerous rhinologists who now devote themselves to this region; while operations upon the nose and naso-pharynx more or less severe have become of striking frequency. That, on the whole, good to humanity has resulted from this great activity cannot be doubted. Unfortunately, however, it often happens, from the imperfection of human agency, that with improved and increased methods of treatment there is involved the danger of doing mischief. The middle ear, from its intimate connexion with the nasal channels, being in fact an offshoot from these, is specially exposed to danger from energetic nasal treatment. It may therefore be useful at the present time to draw attention to this source of danger to the middle ear, and to the precautions calculated to avert such danger.

### NASAL IRRIGATIONS.

I shall consider first the risks attending the use of irrigations to the nose, such as Weber's douche, the syringe and simple sniffing. Since the case reported by Roosa of New York in 1869 of acute otitis media, followed by pyæmia, caused by Weber's nasal douche, many instances of acute purulent inflammation of the middle ear arising in this way have been placed upon record. Attention has also been drawn to this source of danger by Knapp, Elsberg, von Tröltzsch, Politzer, Weber-Liel, Berthold, Guye and others. My own experience has taught me that the entrance of liquid into the middle ear through the Eustachian tube during the use of the nasal douche or syringe, is a very common occurrence. This accident is fortunately, however, by no means always followed by inflammatory mischief. Patients, especially children, frequently mention that they experience pain in the ear during the act of syringing, although no real mischief results. On the other hand, serious mischief to the ear may ensue. Purulent disease with all its possible consequences, or simple catarrh with temporary or permanent injury to the hearing, may without doubt be a consequence. While many of the cases of purulent middle-ear disease excited in this way have been mild and short in duration instances are, in my experience, not very uncommon in which the disease has assumed a persistent and even serious character. I can recall several cases which illustrate this. A young lady who had daily for nearly a year used an alkalo-saline solution, by means of the syphon nasal douche, suddenly while in the act of using the douche became conscious of the liquid passing up into the middle ear. Intense pain in that ear was immediately experienced, followed by suppuration, perforation of the membrane and, ultimately, by caries and necrosis of the mastoid. I operated on the mastoid, and, after many months of great distress and anxiety, the purulent disease was brought to an end, leaving behind, however, a permanently damaged tympanum. More recently a gentleman, after the

employment of the posterior nasal syringe by a medical man, was seized with a purulent disease of the middle ear. He was confident that it followed immediately after and was caused by the injection of the liquid. The purulent disease proved extremely obstinate, involving months of treatment before the secreting process was brought to an end, leaving, however, a permanent perforation. Still more recently a patient, whose ears had hitherto been in a sound condition, was under treatment for an affection of the nasal passages. This treatment included the use of Weber's nasal douche. Purulent disease was excited in both middle ears, which, from the manner of its onset, was clearly due to the entrance of the liquid into the middle ears. The suppuration assumed a most persistent character, and the perforations increased so as to involve a large part of each membrane. Serious deafness ensued, and ultimately, after the use of many different methods of treatment, the secreting process was brought to an end, leaving behind large perforations.

What are the conditions which favour the entrance of liquid into the middle ear during the use of the syringe or douche? Structural peculiarities in the nasal passages and Eustachian tube, existing naturally or induced by disease, are probably the most important factors. In children, for example, owing to the smallness of the naso-pharyngeal space, the width and shortness of the Eustachian tubes, their limited control over the muscles of deglutition, there is more likelihood of liquid injected into the nasal passages finding its way into the middle ear. Likewise in adults, whose Eustachian tubes have been rendered abnormally patent by atrophy of the mucous membrane, or where the muscular mechanism of the Eustachian tube has been impaired, the resistance to the passage of air or liquid is much diminished. In those conditions liquids injected into the nasal passages or drawn in by the patients, however carefully, are apt to find their way into the tympanic cavity. In one of the cases just referred to there was marked imperfection in the due and firm closure of the Eustachian tubes. Of these structural peculiarities, however, the partial or complete impermeability of one or other nasal passage or of the cavity of the naso-pharynx is the most fruitful source of accident. Such impermeability is common, and may be due to deflection, exostosis, or enchondrosis of the septum, to hypertrophic or other swelling of the turbinated bodies, or to post-nasal growths. When one of the nasal passages is thus closed and liquid is injected into the opposite nasal passage by a syringe, the nozzle of which fits tightly into the orifice of the nose, a passage of liquid into the middle ear will be an almost certain result.<sup>1</sup> The employment of strong force, either from too great height of fall in the case of Weber's douche or from excessive pressure upon the piston in ordinary syringing, is always improper, but is especially mischievous when there exists any of those forms of obstruction. It is to be carefully noted that in any case, even when no structural peculiarity exists and when the syringe is used with every caution, *the performance of the act of swallowing during the passage of the fluid through the nasal passages greatly favours the entrance of the liquid into the middle ear.* Another danger is that the liquid still remaining in the crevices of the naso-pharynx, shortly after the injection, is often impelled into the middle ear if the patient blows the nose vehemently or sneezes.<sup>2</sup>

I have said that liquid frequently finds its way into the middle ear without any injurious effects. What are the circumstances which determine injury when liquid finds its way into the middle ear? A middle ear predisposed to inflammation, either through hereditary tendency, a past attack or a present chronic disease, is of course much more apt to be injured by the entrance of the liquid. The force by which the liquid is propelled into the ear must to some extent determine the effect. The character of the fluid, however, especially in regard to temperature, strength and purity, is a still more important factor. A proper degree of warmth is essential to safety: we know that cold liquids injected into the ear through the external auditory canal are apt to prove injurious; they must prove at least equally injurious when forced through the Eustachian tube. The habit of drawing or sniffing cold water into the nasal passages, indulged in by some persons with the idea of curing or preventing cold in the head, is probably responsible for a number of middle-ear inflammations. This method of irrigating the nose is no doubt

often mischievous, especially where the Eustachian tubes are abnormally permeable.<sup>3</sup> Irritating solutions finding their way into the middle ear must of course be more likely to excite inflammation than those of a mild character. The rôle played by mucus, pus or blood forced from the naso-pharynx into the middle ear is not easily determined, although when accompanied by pathogenic organisms, such as those peculiar to ozæna, diphtheria, scarlet fever and certain forms of nasal catarrh, they must prove most important sources of mischief. When a combination of all these conditions and causes exists in the one case the danger to the middle ear must be great, if not unavoidable, and it is probable that such a combination not unfrequently exists.

#### THE GALVANIC CAUTERY AND CORROSIVE SUBSTANCES.

Let us now consider to what extent the galvanic cautery and corrosive substances—such as chromic acid—are responsible for the production of mischief in the middle ear. Exciting as they do more or less inflammation in the tissues of the nose, it would not be surprising if extension to the middle ear sometimes took place. I believe, however, that such mischief, when it does occur, is frequently due to the neglect of certain precautions after the cauterisation. These applications being usually made in the doctor's house, exposure to the air—travelling, it may be, to a distant part—tends to increase the irritation and leads to its extension from, say, the inferior turbinated body, to the Eustachian tube immediately behind. The following case illustrating this came lately under my observation. The left nasal passage of a lady was cauterised with the galvanic cautery in London. On the day following she travelled to Glasgow, feeling as if she had a severe cold in the head with violent sneezing. On the day after her arrival in Glasgow she was seized with severe pain and throbbing in the ear corresponding with the side which had been cauterised. When I saw her a week afterwards she suffered from acute otitis media on the left side, with implication of the mastoid, which, in the region behind the ear and in the posterior wall of the auditory canal, was bulging and painful; neither discharge nor perforation had taken place, but the hearing power was almost abolished in that ear. After leeching the mastoid and incising the posterior wall of the external auditory canal, with only temporary benefit, it was proposed to perforate the mastoid behind the auricle, but, after consultation, it was decided, owing to the subsidence during the previous twenty-four hours of the pain over the mastoid, to postpone the operation. The hearing began to improve and the bulging of the posterior wall of the canal gradually diminished, with ultimate but very slow recovery. In this case I do not think that one would be justified in positively asserting that the cauterisation was the direct cause of this middle-ear mischief, although the order of events—the cauterisation followed by the nasal irritation, then by the pain in the corresponding ear—would lead one to suspect that the operation on the nose had something to do with what followed. Syringing the nose after cauterisation, when the passage is obstructed from swelling, is apt to force liquid into the middle ear and thus excite mischief. Probably the introduction of micro-organisms along with the applications, such as when the part of the electric cautery near to the burner has been imperfectly cleaned and disinfected, may be the means of exciting suppurative inflammation in the middle ear. When the cautery is applied near to the mouth of the Eustachian tube the danger is of course greater. Hence cauterisation of the naso-pharynx is particularly apt to injure the middle ear, as recorded cases prove. Galvanic cauterisation of the pharynx granular pharyngitis may likewise be followed by acute purulent inflammation of the middle ear. Such a case is within my knowledge. Gruber also remarked at the meeting of the British Medical Association in Nottingham that the galvanic cauterisation of the wall of the pharynx may, by injury to the muscular fibres beneath, damage the muscular mechanism of the tube. In regard to the use of chromic acid I have not yet seen a case of middle-ear mischief from the use of this corrosive, but, judging from the irritation and swelling of the mucous membrane usually produced by this substance, implications of the middle ear might occasionally be expected. In a paper by Eitelberg<sup>4</sup> there are descriptions of cases of troublesome middle-ear suppuration excited by chromic acid applied to the nasal mucous membrane. When the galvanic cautery or chromic acid has to be applied to the nasal mucous membrane too great care cannot be enjoined upon the patient to avoid exposure to cold.

## OPERATIONS ON NOSE AND THROAT.

Let us now consider to what extent the greatly extended use of operations on the nose and naso-pharynx may be regarded as a source of mischief to the adjoining cavity of the middle ear. The removal of adenoid vegetations from the naso-pharynx has become of late years one of the commonest of operations. As an operation most frequently performed in cases of defective hearing I have had very considerable experience of it. While I have no doubt seen a considerable number of cases in which, after the removal of these growths, a purulent inflammation affected one or both middle ears, I have not had experience of any case in which this assumed a serious character—none so serious as we have seen to happen after the nasal douche. I observe, however, that Dr. Gorham Baton, at the twenty-fifth annual meeting of the American Otological Society, describes a case in which inflammation of the mastoid cells and periosteal abscess followed upon the operative removal of these vegetations. I have, however, seen at least one case in which permanent aggravation of deafness followed this operation, where a chronic adhesive catarrh of the middle ear existed. I think in this form of deafness we should be very cautious in operating upon the naso-pharynx or nasal passages. While the ordinary exudative catarrh may be very much benefited in this way, there is no doubt a fear of doing more harm than good in these adhesive or hypertrophic forms of catarrh. Most aural surgeons have seen cases of inflammation of the middle ear following the removal of tonsils and nasal polypi. The extent to which operations upon the nasal septum and turbinated bodies and the forcible mechanical distension of the nasal passage by instruments constructed on the principle of the glove stretcher, so frequently performed of late years, affect the middle ear prejudicially has not yet come to light. Eitelberg describes an obstinate suppuration of the middle ear following the removal of the posterior end of the inferior turbinated body. It is fitting also to refer here to the possibility of exciting inflammation of the middle ear in cases where the posterior nares have been plugged in consequence of bleeding from the nose.<sup>5</sup> Serious mischief has arisen in such cases from the retention of the plugs too long and the production thereby of septic inflammation in the middle ear. One case of death is reported from this cause, owing to cerebral complication. In considering the liability of the middle ear to receive injury from any of these forms of nasal treatment, it is to be remembered that here, as in all organs of the body where the vulnerability of the organ is increased by hereditary weakness and by previous or existing disease, the action of a local cause, be it the entrance of liquid into the ear or the production in the neighbourhood of the middle ear of inflammatory irritation or septic mischief, is fraught with the greatest danger. I would venture to urge upon rhinologists the importance of giving due attention to these considerations when treating the nasal regions. Do not order the nasal douche without considering the possible effects upon the middle ear, especially where an old inflammatory disease or a marked tendency to deafness already exists. Do not hold out vain hopes to persons suffering from incurable deafness that cauterisation of the inferior turbinated body, the removal of a tonsil, perhaps only slightly enlarged, or of a vegetation in the naso-pharynx, will restore or improve the hearing. Instead of improvement the very opposite result may follow. I have had patients coming to me, suffering from incurable sclerosis of the middle ear and labyrinthine mischief, who were encouraged to expect great improvement of the hearing if such operative measures were submitted to; such expectations being held out without even the preliminary precaution of examining the ear. It is not surprising that the effect of such treatment is often to increase rather than to improve the deafness. It is a great mistake to conclude in such forms of deafness that if a deflection of the septum or a degree of hypertrophy of the inferior turbinated body exists, operative measures should immediately be adopted. Even when some adenoid growths exist in the naso-pharynx, in sclerosis or adhesive catarrh of the middle ear, it is a question for serious consideration whether operative interference with these growths may not excite an increase in the morbid process in the ear, instead of benefiting them. I cannot do better than here quote from the recent work of my friend, Dr. McBride. He says: "If ten persons who, in answer to leading questions, state positively that they are not in any way troubled by symptoms referable to their nose be examined the probability is that more than half will show such evidence

of disease—e.g., spines on the septum, thickening of the mucosa over the turbinated bodies &c.—as would lead to severe operative measures being advised by many rhinologists if they were to carry out what they advocate. This excessive operative zeal appears to me to be a great danger, threatening as it does the credit of our profession as a whole, and rhinology in particular. Recently an authority is reported (wrongly reported, I trust) to have stated before a medical society in America that he cured diseases of the internal ear by operating on the nose, and his remarks do not seem to have excited laughter. I have dwelt perhaps unduly on these points, but the practical outcome I desire to lead up to is this: let no surgeon be induced to operate on the nose simply because there is some degree of hypertrophy of the mucosa unless the symptoms are sufficiently important to warrant such interference."

## PRECAUTIONARY SUGGESTIONS.

I shall now state as concisely as possible the precautions which to my mind should be kept in view when treating the nasal passages and naso-pharynx, in order to avoid or diminish the risk of exciting disease in the middle ear. 1. Patients before using the nasal syringe, Weber's douche or the hand douche, should be carefully instructed by the surgeon in their proper and safe use. 2. Previous to injecting fluids by the syringe or Weber's douche into the nose, or prescribing such, the nasal passages should be carefully examined, and if one should be found obstructed the fluid should be injected *into the obstructed passage*. 3. The nozzle of the syringe should not tightly close the nostril and during the injection of the fluid the stream should be frequently interrupted. 4. If a syringe is employed, too great force must not be used, especially if there be resistance to the flow of the fluid from one nostril to the other; if Weber's douche is employed the fall must not be too great—not more than two feet. 5. The fluid injected should always be comfortably warmed—say 80° to 90° F.—and it should hold in solution a saline, such as a 1 per cent. solution of common salt or bicarbonate of soda, while in ozæna or other bacterial diseases a definite antiseptic should be employed. 6. The act of swallowing must carefully be avoided during the douche; this is aided by breathing through the mouth. Eitelberg suggests that the patient should protrude the tongue so as effectually to prevent the act of swallowing. 7. In the case of infants or very young children, or in adults whose Eustachian tubes are abnormally permeable, the syringe or Weber's douche should not be employed. The liquid should in these cases be poured into the nasal passages with a spoon or other suitable appliance while the patient (if old enough) should sound the vowel "a." 8. The patient should not blow his nose or, if possible, sneeze for at least fifteen minutes after; he should be instructed that in the event of the liquid entering the ear, he must swallow several times with the nostrils closed. 9. After operations on the nose or naso-pharynx, or the use of corrosive substances which may produce swelling or obstruction, the syringe should be avoided or used with great caution, for a few days, during which the patient should be careful to avoid exposure to cold or septic influences. 10. In operations or cauterisation great care should be taken to secure cleanliness and an aseptic condition of the instruments or appliances used. If the finger-nail is employed to scrape away vegetations there is obviously special need for precautions in these directions.

Glasgow.

## ON THE DIAGNOSIS OF THE DIFFERENT FORMS OF PROSTATIC ENLARGEMENT.

By C. MANSELL MOULLIN, F.R.C.S. ENG.,  
SURGEON TO THE LONDON HOSPITAL.

ONE of the natural results of the recent advances in the surgical treatment of enlargement of the prostate is the demand for a higher degree of accuracy in the diagnosis of the different forms assumed by the growth. So long as passing a catheter at longer or shorter intervals was the only method for giving relief exact measurements were not of much consequence. Then the chief question was the amount of residual urine and the number of times the patient was disturbed in the twenty-four hours; the growth might extend backwards towards the rectum or upwards into the bladder; or it might spread into the walls of the urethra and compress the passage into a narrow slit. So long as it did not obstruct

<sup>5</sup> Gellé in Archives de Laryngologie, No. III., 1892.

too seriously the passage of a catheter or prevent the patient manipulating one for himself the particular shape it assumed was not material. To-day all this is changed. Now that it is possible to effect a radical cure in a large proportion of cases and dispense with the use of an instrument it has become a matter of the highest importance to ascertain the exact size, direction and position of the outgrowth in every instance in which other conditions render such a proceeding advisable. One form can be dealt with most easily through the perineum; another supra-pubes; a few require a combination of the two methods; in one case the dimensions may be such as almost to preclude the idea of radical cure; in another the growth may be so small or so situated that it can be effectually removed by comparatively speaking a minor operation.

To this end museum specimens are of but little value. Nearly always they are taken from the bodies of those who have died in an advanced stage of the disease from complications it has caused, long after the time for radical treatment has passed by; and even when they are not they give but a very imperfect idea of the condition of the parts during life. In its normal state the gland is not a very vascular structure, although it is surrounded by a voluminous plexus of veins; but when it is enlarged and partial retention has commenced, the constant straining, the passage of instruments and the other troubles incident to this disorder sooner or later give rise to attacks of congestion, which may be so intense and prolonged as to lead to very considerable alterations in its size and consistence. I have known the walls of the prostatic urethra so tense and swollen that a full-sized catheter could scarcely be pushed down it; yet two days later, at the necropsy, when all that remained of the congestion was the discolouration of the mucous membrane and a few thrombi in the veins, the forefinger could be introduced with ease. Measurements, if they are to be a guide in the selection of cases and methods, must be taken under the conditions that are present during life.

Rectal examination is only of use when it gives positive information and then only in a certain proportion of instances. As McGill pointed out, the prostatic enlargements which give rise to urinary symptoms are intra-vesical (and urethral), not rectal. The cases in which operation is most successful are those in which there is a median projection overhanging the orifice or a trilobed outgrowth surrounding it and meeting over it as the bladder contracts. Quite small growths in this situation may cause complete retention and that in a very early stage of the disease, while the patient is comparatively young and his kidneys are still sound. Yet in a certain proportion of these cases there is either no rectal enlargement at all or so little that it rather tends to throw discredit upon the diagnosis than to assist it. The converse, it is true, deserves more reliance. When the growth projects far into the bowel there is generally some elongation of the prostatic urethra; but this is not invariable, and even when it is present it does not follow that there is of necessity loss of power in the wall of the bladder with accumulation of residual urine.

Examination of the urethra with a catheter or sound gives fuller details. The length of the prostatic dilation is easily measured, and occasionally the presence of a dilatation can be detected anterior to the bladder in the substance of the gland. So far as the general shape is concerned a short-beaked metal sound is the better guide. Combining the two methods, the rectal and urethral, the thickness of the tissues that separate the two passages in the middle line can be estimated with tolerable accuracy; if the sound is reversed in the bladder it is sometimes possible to form an idea of the extent to which the growth has invaded the posterior margin of the vesical outlet and the floor of the trigone beyond; and occasionally the existence of a median projection may be suspected from the peculiar jerk communicated to the instrument when it is reversed and moved slowly from side to side, but the enlargement must be very firm and well marked to show so much. Beyond this it is only in rare cases that any further information can be obtained through the ordinary channels. The cystoscope, which has done so much for the bladder, is of very little service where the prostate is concerned. It may reveal the existence of an overhanging lobe when it projects well into the bladder, or show the presence of an ulcer or a fissure at the neck, but it reveals little or nothing of the shape of the rest of the gland, and of course can give no information as to its consistence; and the clinical symptoms, except in those instances in which complete retention occurs suddenly without any evidence of congestion or thrombosis, merely indicate the necessity for something further in the

way of relief without furnishing a clue as to the way in which it is to be obtained.

In all these methods of investigation the posterior portion of the gland in the middle line is the only part that receives any attention. The lateral lobes may be enormously enlarged and compress the urethra into a slit, but unless the growth is so irregular in shape that the point of the sound is caught or turned to one side as it passes by or has spread so far into the bladder that the projection can be seen through a cystoscope there is nothing to show whether they are affected or not. Yet in a large proportion of cases they and not the so-called median lobe are the real offenders. By the increase in their length they raise up between them a fold of mucous membrane (often containing prostatic tissue) which stretches across behind the vesical orifice and prevents the bladder emptying itself. By the increase in their thickness they compress the urethra into a narrow slit, through which when there is the least congestion the bladder is unable to force its contents. They in the large proportion of cases are the centres from which the glandular growth spreads beyond its normal boundaries into the wall of the urethra, and even in those instances in which the immediate cause of retention is the presence of a median valve they are of very material assistance by the way in which they make the opening rigid and unyielding. In short, if the operation is to be a radical one, with a prospect of permanent cure, they require to be dealt with as thoroughly as the rest, and accordingly it is of the first importance to obtain beforehand exact information with regard to their relative size, shape and density.

There are two methods not in common practice by which something may be gained before resorting to digital exploration. Of these one is only of use for distinguishing between valvular obstruction and compression of the urethra. If a catheter with a terminal orifice is passed down to the apex of the prostate and connected by a rubber tube with a funnel containing warm boracic solution under normal conditions a pressure of a very few inches is sufficient to make the fluid enter the bladder. Roughly the measurement may be taken by the height to which it is necessary to raise the funnel and the patient's sensation tells at once when the fluid begins to enter; but if greater accuracy is desired the tube may be connected with a manometer by means of a side branch. In cases of purely valvular obstruction the fluid enters freely and quickly and at the ordinary pressure; on the other hand, when the canal is compressed it remains stationary until the funnel is six feet or more above the patient's body and even then it only trickles in. It is usually advisable to repeat this after an interval of a few hours or on the following day, and care must be taken that a catheter is not passed shortly before the experiment is tried.

The other method is based upon the relation that exists between the size and shape of the prostatic urethra and that of the prostate itself. It is true that this must not be pushed too far; the prostate may be distorted and covered with outgrowths without of necessity entailing much alteration in the channel that runs through it; but leaving on one side cases that present conspicuously exaggerated features and restricting it to the ordinary type of overgrowth, in which there is an ever-increasing difficulty in emptying the bladder, some degree of proportion certainly does exist in the majority; and although it is impossible to define accurately in every instance the parts that are enlarged or the extent to which they have grown, great alterations in the dimensions of the urethra are practically always associated with definite changes in the shape and size of the gland.

Measurements should be taken in the middle of the prostatic urethra and at or as near as may be to the vesical orifice. The former are the more valuable, for when the alteration in size or distensibility at the outlet is very marked, the shape of the gland is usually too irregular for accuracy. The opening, for example, may be distorted into a semi-lunar shape by the growth of a median projection from behind and give an antero-posterior diameter that is altogether deceptive. In the middle of the prostatic urethra this rarely happens. There an increase in the antero-posterior diameter without any great change in the transverse one always indicates overgrowth of the lateral lobes. If the measurement diminishes rapidly towards the bladder, and if the urethra is at the same time increased in length, it is proof not only that they are enlarged, but that they have raised up between them a fold of mucous membrane across the posterior boundary of the outlet; and if there is at the same time much of an angle in the posterior wall, stopping the passage of a catheter with an ordinary curve, it shows that the fold is of considerable

thickness, projecting forwards as well as upwards and contains therefore an outgrowth of glandular tissue. In other words the vesical orifice is raised, displaced forwards and surrounded either by a continuous collar or by three projecting eminences which meet together over it when the bladder contracts. The lateral diameter deserves an equal amount of attention. Normally the transverse section of the prostatic urethra about its centre is crescentic in shape with the convexity forwards. When there is general enlargement this becomes altered into a triradiate star and then increased width is a sure indication that there is overgrowth in the posterior wall, involving not merely the vesical outlet, but the urethra as well—such a growth, in short, as can scarcely be dealt with satisfactorily by the supra-pubic route alone.

It is more difficult to ascertain the extent to which the urethra is displaced in the substance of an enlarged prostate. Usually there is very little overgrowth in front, but I have met with one instance in which this was so great that the channel lay a long way behind the centre, and in another in which prostatectomy was performed it is recorded that the anterior growth was the main and almost the sole obstruction. It may be suspected if when the prostate is distinctly enlarged the antero-posterior diameter of the urethra is not

the other, the interior of the prostatic urethra can be mapped out with perfect accuracy, and in many instances, owing to the difference in the resistance presented by the walls, the nature of the growth can be ascertained as well, whether it is soft, nodular and adenomatous or hard and dense like fibroid. Combining the knowledge obtained by these measurements with what is revealed by rectal examination and cystoscopy, an accurate opinion as to the size and shape of the overgrowth can usually be formed in those cases in which operation is advisable without having recourse to digital exploration.

Wimpole-street, W.

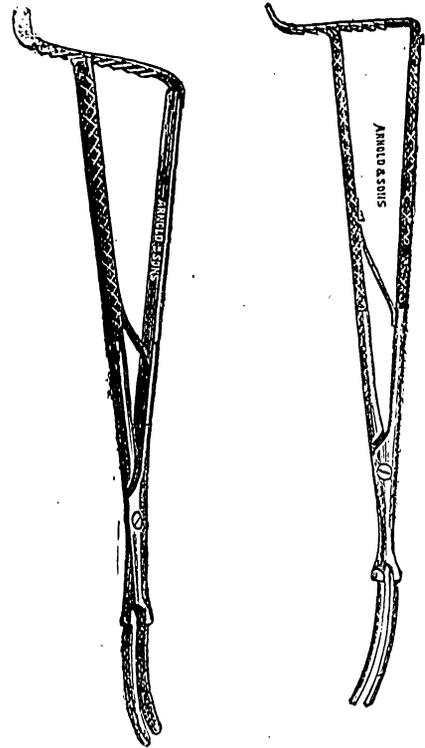

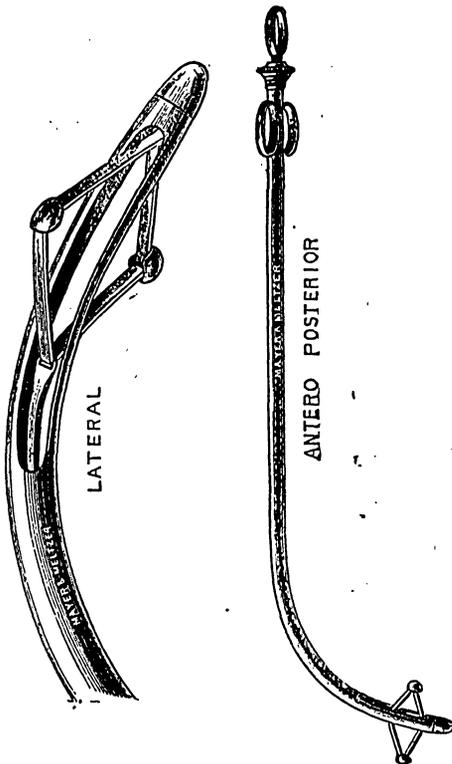

UTERINE DILATORS.

By C. YELVERTON PEARSON, M.D. R. U. I., F.R.C.S. ENG.,  
SURGEON TO THE COUNTY AND CITY OF CORK HOSPITAL FOR WOMEN  
AND CHILDREN ETC.

ANYONE introducing a new form of uterine dilator owes some apology to the profession, yet I think the great variety of such instruments already in existence is in itself an evidence that no form has given perfect satisfaction. For some years past I have been accustomed in cases where I desired to effect rapid dilatation of the cervix, first to pass

FIG. 1.

FIG. 2.

increased and the channel is unusually straight, but it cannot be proved. The same thing must be said of irregular or extreme forms of overgrowth; it is seldom that they can be accurately defined without digital exploration.

Messrs. Mayer and Moltzer have made for me two instruments for taking these measurements, very simple in construction. Each consists of a diamond-shaped metal frame, hinged at the four angles to allow of expansion and contraction and enclosed in the curve of a prostatic catheter, part of the wall of which has been cut away. In the one the sides are open to allow of lateral expansion; in the other the front and back for antero-posterior measurement, the projecting angles in each case being protected by little rounded buttons upon the hinges so that the mucous membrane may not be hurt or bruised. Expansion and contraction are carried out by means of a stilet gliding backwards and forwards in the shaft and terminating in a finger ring, and the measurement scale, which is marked upon the handle of the stilet, gives at a glance the width to which the diamond is opened at the moment. By means of these, introducing first one and then

graduated metallic dilators, and when the canal was sufficiently opened by this means, then to effect further dilatation by means of a modified glove-stretcher. I have now got Messrs. Arnold and Son to make two instruments on the latter principle, which can be used separately or simultaneously, and by means of which the cervical canal can be rapidly and safely enlarged, in all cases where the cervix is sufficiently yielding to justify rapid dilatation, from a diameter slightly exceeding that of an ordinary uterine sound to a size sufficiently large to readily admit one finger. The accompanying illustrations will render a full description of the instruments unnecessary. But a few points and the method of use require special mention. The smaller instrument with the blades closed can be passed without difficulty through any uterine canal that will admit an ordinary uterine sound. The blades are curved and open in an antero-posterior direction on compressing the handles. The latter are provided with a catch working on a rack which permits their slow approximation, but checks their tendency to separate until it is so desired. When the full amount of dilatation has been effected, the blades of this

instrument are permitted to close; it is then withdrawn, and the larger one is substituted. This is used in a similar manner, except that the blades expand in a lateral direction—i.e., at right angles to the other. When the larger instrument has been compressed so as to produce the fullest expansion of the blades, if any further dilatation be desired, it can be accomplished by inserting the smaller dilator between the expanded blades of the larger one, and again opening them. But for the purpose of curetting this will not be found necessary. In cases where the cervix is rigid and rapid dilatation to any considerable extent is therefore contraindicated, the following method will be found most satisfactory:—First, use the small dilator until the canal is sufficiently opened to admit a medium-sized tent, then introduce a tent, and permit it to remain for three or four hours. At the end of this time the cervix will have become so soft and yielding that the full amount of dilatation required for ordinary purposes can be readily accomplished with my dilators.

For these dilators I claim the following advantages:—1st. Only two instruments are required for all ordinary purposes. 2nd. They will rapidly and safely dilate the cervical canal from its ordinary size to a diameter sufficiently great to admit a full-sized finger. 3rd. Owing to the way in which the blades open, they will dilate the os internum to a slightly greater extent than the os externum, a point which most of the dilators in use fail to accomplish. 4th. The compressing force of the hand, while capable of exerting all the force desirable, acts as a guide to the amount of pressure and resistance, and can be used in a delicate manner, so as not to risk any injury by over-stretching, having this great advantage over any screw-like mechanism. 5th. As the blades are only two inches long from the projecting shoulders they will not come in contact with the fundus.

Sidney-place, Cork.

### UNIVERSITY COLLEGE HOSPITAL.

#### TWO CASES OF EXOSTOSIS INVOLVING JOINTS; REMOVAL THROUGH THE JOINTS; COMPLETE RELIEF.

(Under the care of Mr. ARTHUR BARKER.)

THESE cases illustrate the safety with which exostoses may be removed at the present day even when their removal involves incision into a large joint. Before the system of antiseptics had been sufficiently developed surgeons would have hesitated before attacking such bony outgrowths, however much they might have interfered with the neighbouring joint. They may, however, now be removed, and frequently are, without risk of pyæmia or bone inflammation, if they simply cause unsightly deformity. Should they interfere with the utility of a limb, give rise to neuralgia or other symptoms due to pressure or be increasing rapidly, few surgeons would hesitate to remove them. Innes has recorded a case in which an exostosis of the head of the tibia caused gangrene of the foot and leg by pressing on the arteries, and Braun also relates a case of ankylosis of hip due to the presence of such a growth. We are indebted to Mr. J. B. H. White, surgical registrar, for the notes of the cases.

CASE 1.—A man aged fifty-eight, an engineer by occupation, was admitted to University College Hospital on March 17th, 1891. Eight months before admission he had noticed a little tumour the size of a pea just above the flexure of the left elbow-joint. It could be shifted from side to side and the movement was often accompanied with grating. There was no pain, but as the swelling gradually enlarged increasing difficulty in bending the elbow made him seek relief. There was no history of an injury. On admission there was, in the position indicated above, a prominent swelling of bony hardness and as large as a walnut; with the arm extended the summit of the swelling was crossed by the

median basilic vein and just internal to this by the brachial artery; the mass then appeared to be fixed. When the elbow-joint was flexed to a right angle the tumour was movable from side to side, but not in the direction of the length of the limb. The tumour appeared to be altogether beneath the brachialis anticus muscle. The next day an incision two inches long was made over the summit of the swelling. The median basilic vein and brachial artery were held aside by hooks. The fibres of the brachialis anticus muscle were divided longitudinally over the tumour, and when the latter was reached the fibres of the muscle had to be separated from its surfaces, to which they were closely attached. In removing the lowest part of the tumour the elbow-joint was opened. The wound was sutured with silk, with a drain consisting of several strands of silk, and was dressed with dry salicylic wool. The arm was placed on a splint in a nearly extended position. The parts removed at the operation consisted of a piece of bone measuring  $2 \times \frac{1}{4} \times \frac{3}{8}$  in. Both surfaces were covered by torn muscle fibres, in places distinctly tendinous. At the lower end of the fragment were two articular surfaces separated by a notch; these surfaces were covered by very dense fibrous tissue and not by cartilage. One of the articular surfaces on the anterior half of the other articulated with the coronoid process of the ulna, in which there was a pit to receive it; the posterior half of the latter surface articulated with the humerus. In the evening of the day of operation the temperature reached  $101.6^{\circ}$ ; it had regained the normal by the fourth day after operation and remained normal afterwards. The wound was dressed on the second day after operation; the discharge was serous. The wound was dressed again on the sixth day and the silk drain removed, and on the twelfth day, when all the sutures were removed. There was a small part unhealed in the centre of the wound from which some clear fluid like synovia was discharged. The patient left the hospital on the seventeenth day after the operation with the wound soundly healed and with perfect use of the limb.

CASE 2.—A woman aged forty-four was admitted to this hospital on Aug. 10th, 1891. Twenty-six years ago she was run over by a travelling coffee stall, the wheel of the vehicle passing over her legs just above the knees. Six years later she first noticed a little lump just above the left knee-cap. It was then no larger than a pea. During the last twenty years it had gradually increased in size, but more rapidly during the last two or three years. On admission there was a bony outgrowth from the front of the left femur forming a considerable prominence on the front of the limb a finger's breadth above the upper margin of the patella; it was completely covered by the quadriceps extensor and appeared to be pedunculated; when the knee-joint was flexed an interval of three inches and a quarter separated the patella from the exostosis. On the third day after admission an incision three inches long was made on the outer side of the swelling and deepened through the muscle; the supra-patellar pouch of the knee-joint was opened; the exostosis was cut off with an osteotome and the base afterwards rendered smooth; the edges of the posterior layer of the synovial membrane of the joint were sewn together by a continuous silk suture over the bony defect and the skin wound by interrupted sutures; the wound was dressed with dry salicylic wool; it was not drained. A back splint was placed on the limb. With the exception of a rise to  $100^{\circ}$  on the day following the operation the temperature was normal throughout. The wound was dressed on the third and again on the tenth day after operation. On the latter day all the stitches were removed and wool and collodion applied. The patient left the hospital on the fourteenth day with the wound quite healed and with perfect movement in the joint. The parts removed at the operation consisted of a flat oval piece of bone measuring one inch and three-eighths by three-quarters of an inch. It was composed of spongy bone, with a thin layer of compact tissue all round the sides and on the summit a layer of cartilage one-sixteenth of an inch thick. The periosteum covering it was much thicker than normal.

Remarks by Mr. BARKER.—Of the numberless cases of bony exostoses which every hospital surgeon meets with it must be admitted that very few ever imperatively require operation. Those which lie in the neighbourhood of joints, however, are the exception to this rule, interfering as they often do with the movements of the articulation. Such I have frequently had to remove by operations of more or less severity. Both the cases recorded above I believe to have been originally exostoses, although in the first the bony mass was movable when first seen and was seated in the insertion of a tendon.

It is, I believe, rare to find bony growths in the substance of tendons except where they spring from bone. I cannot help thinking that this man had a pedunculated exostosis springing from the coronoid process and running up the insertion of the brachialis anticus, which ultimately became broken off at its base and then moved with the tendon in which it lay, causing much discomfort and weakness to the man, who worked much with the hammer. The case of the woman was one of a true pedunculated spongy exostosis in a not very common position, though we have specimens in our museums which illustrate the variety clearly. Like the exostosis in the first case it had appeared rather later in life than is usual, or, at all events, it only gave trouble in middle life. Such cases are pathologically very remarkable if we accept Cohnheim's theory as to the production of exostoses. His explanation seems to fit in better with their appearance during the first two decades of life, which is the rule rather than with their production in middle life. Surgically these cases show how easily and with what impunity joints may be opened provided we are confident of securing perfect asepsis and subsequent rest, and in both instances large joints were opened freely and large portions of bone were removed from them without producing the slightest reaction or causing the least impairment of function subsequently.

## Medical Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

#### *Supra-Vaginal Amputation of Cervix Uteri for Cancer.*

An ordinary meeting of this Society was held on Dec. 13th, the President, Sir Andrew Clark, in the chair.

Dr. LEWERS read a paper on some points in the Supra-vaginal Amputation of the Cervix Uteri for Cancer, with special reference to the methods adopted in cases where, for two years and upwards, the disease had not recurred. He considered the subject under the following heads: (1) The indications and contra-indications for the operation; (2) its mortality; (3) the results as regarded recurrence; and (4) the details of the operation in those of his own cases where the disease had not recurred for periods of two years and upwards. The paper was based on an experience of nineteen cases. So far as the first head was concerned Dr. Lewers would lay special stress on the importance of careful examination under anaesthesia in doubtful cases, with the view of determining their fitness or otherwise for operation. As regarded the mortality, none of the cases succumbed at the operation; as regarded recurrence, full proof was brought forward of the malignant nature of the disease in those cases where the disease had, for periods of two years and upwards, not recurred. The specimens themselves and drawings of them were shown for reference on this point. As regarded the fourth head, he laid stress (a) on the importance of making the preliminary incisions for clearing the cervix as far as possible from the diseased tissue; (b) on the importance of removing the cervix in an anatomically complete condition at the level of the internal os uteri; (c) on the little risk involved in opening Douglas's pouch during the operation; and lastly (d) on the apparent value of applying the cautery freely to the "bed" from which the cervix had been dissected out and of cutting off the cervix from the body, after it had been cleared, with the cautery rather than the knife or scissors.

Mr. JESSITT referred to twenty-four cases on which he had operated during the years 1889, 1890 and 1891: fifteen of them were at present without recurrence, five had had recurrence, three he had lost sight of and one died. These results, compared with those of total extirpation of the uterus, stood out very favourably, for Martin of Berlin gave the death-rate of total extirpation at 16 per cent., while in America Post found that a collection of cases gave a mortality of 24 per cent. His own experience of total extirpation was very unfavourable. He thought that Dr. Lewers might have gone further in many of his cases and, instead of cutting off the cervix transversely, he might have removed a cone-shaped piece of the uterus above the level of the internal os. In patients who had not reached the menopause, in order to avoid the danger of retention of the menses he introduced a stem and allowed the uterus

to heal round it, leaving the canal patent. He related an instance in which hæmatometra followed an operation where this precaution had been neglected. In two of his cases the microscopical examination was not decisive as to malignancy, though clinically they had malignant characters. It was of little importance whether Douglas's pouch was opened up or not; he never stitched it up. He had found a tendency to hæmorrhage when the slough caused by the actual cautery came away, and he preferred the scissors to the cautery for the reason that the cautery hardened the tissues and masked any disease that might be left behind.

Dr. CHAMPNEYS advocated the division of the cases into three classes—cancer of the body of the uterus, cancer of the supra-vaginal portion of the cervix and cancer of the vaginal portion of the cervix. For cancer of the body of the uterus vaginal hysterectomy should be performed and in suitable cases this operation perhaps gave the best results of the three. In cancer of the vaginal portion the supra-vaginal amputation should be performed; the disease here did not tend to spread upwards so much as laterally. Where the disease began in the canal of the cervix the case was the least favourable of the three, owing to its deeper seat and its tendency to spread upwards before notice of its presence was given, and when discovered it was found often that the mischief had spread laterally and the operation was often difficult and unsuccessful. There was some doubt as to what was the best operation to be done in these cases, but as the extension upwards was usually a late manifestation, and when this had occurred the disease had already spread so far laterally as to render partial operation inadvisable, the best chance was given to the patient by total extirpation. In considering foreign statistics it should be remembered that vaginal hysterectomy had been done in Germany for many affections other than cancer, such as displacements of the uterus, and therefore their total results should be more favourable than ours.

Dr. ROUTH said that in practice cases were usually met with only at a late period, when the disease had extended towards the internal os. He preferred the écraseur, and especially the electric écraseur, for making the section of the cervix, as hæmorrhage was thus avoided. He had used the actual cautery without consecutive hæmorrhage, but he never applied it above a red heat. He spoke well of the results of the bromine treatment; one part of bromine to five parts of spirits of wine was applied on a tent with cotton wool, and below it plugs were placed which were soaked in carbonate of soda. The bromine should be left in not more than four hours and afterwards a slough half an inch in thickness would separate, glycerole of pepsin being used to dissolve the slough and keep the parts free from odour.

Mr. HULKE said it had been his lot to have charge of a cancer ward at a neighbouring hospital, and he usually had many of these cases under observation; but they generally entered the institution when the disease was too far advanced to render operation practicable. Extirpation could only be of benefit when lateral infiltration was absent and there was but a limited implication of the vaginal walls. Most of the cases which were unfit for the supra-vaginal amputation were equally unfit for complete extirpation. He concurred in preferring the scissors rather than the cautery to make the section of the uterine tissue, and had seen hæmorrhage follow separation of the sloughs when the cautery had been used.

Dr. HEYWOOD SMITH thought that one could go too far in cutting wide of the disease; it was possible to cut out a cone of uterine tissue without entering the utero-vesical space or opening Douglas's fossa. His objection to the écraseur was that it cut on a dead level and was apt to draw in more tissue than was intended. Having cut out a cavity he plugged it with sponges wrung out of very hot water to stop the hæmorrhage and then packed tightly with swabs soaked in a saturated solution of chloride of zinc, plugging the vagina with carbonate of soda tampons. In twenty-four hours he removed the vaginal plugs and in four days the zinc swabs; later a slough separated like the finger of a glove.

Dr. AMAND ROUTH emphasised the importance of making a microscopical examination in doubtful cases and related a case in which a large growth, considered at first to be too far advanced to admit of operation was found to be adenomatous and was successfully removed, there being no recurrence after three years.

Dr. HERBERT SPENCER said that the mortality from the two operations ought not to be compared. He referred to an American paper which appeared recently by Dr. Byrne, President of the New York Obstetrical Society, who gave the

German statistics of mortality after total extirpation at 14.5 per cent. Dr. Byrne had had 400 cases of supra-vaginal operation without a death; he removed the cervix by means of a galvano-cautery knife, and he attributed his wonderful absence of recurrence to the "roasting" of the tissues by means of the hot knife. Mr. Spencer added that in the majority of cases, if the section were made with a knife, the limit of the disease could be accurately seen. He had seen pyometra in one case in which the cervix had been removed with the scissors and he feared that the use of the stem might increase the risk of septic infection.

Dr. LEWIS, in reply, said that most observers seemed to agree that the mortality of total extirpation was about 16 per cent. He did not see the advantage of removing much of the body of the uterus; if a case was found at the operation to require this, it was better to perform total extirpation. Though he had never met with occlusion after the operation he had seen considerable narrowing, which had led to a little increase of the dysmenorrhœa usually present in the case. He had never met with hæmorrhage after the actual cautery, but had seen it as a secondary phenomenon after the separation of the chloride of zinc slough on the tenth day. He admitted that cancer of the vaginal portion of the os was much more amenable to treatment than when the disease began in the cervical canal because it was recognised earlier. He insisted on the importance of keeping the cervix in an anatomically entire condition during removal. The statistics of vaginal hysterectomy when performed for cancer of the body of the uterus should be kept quite separate from those for cancer of the cervix, for the operations differed so much from each other. He had had no experience of the bromine treatment. Though he admitted that the majority of cases which were unfit for the supra-vaginal amputation were unfit also for complete extirpation, yet he showed a specimen which was an exception to this rule. He had tried the treatment of advanced cases by scraping and chloride of zinc plugs; and though every now and then a case would improve for three or four months, they then rapidly relapsed and became as bad as before; he had therefore abandoned this palliative method.

## MEDICAL SOCIETY OF LONDON.

### *The Irregular Heart.*

AN ordinary meeting of this Society was held on Dec. 12th, the President, Mr. Hutchinson, in the chair.

Dr. SANSON read a paper on the Irregular Heart. He stated that it was a review of forty-seven cases presenting pronounced irregularity of the heart for long periods, which had all been under his own observation, all of them being independent of structural disease as a protopathic lesion. They were considered in two groups, the smaller group of ten cases being all examples of Graves' disease. The mode of observation was described and it was recommended—(1) to observe the radial pulse in the usual way; (2) to count the heart beats and observe the rhythm by auscultation; (3) to observe the radial pulse and auscultate the heart simultaneously; (4) to cause the patient to elevate one or both arms whilst the observer auscultated the heart region so that the effect of increased extra ventricular pressure might be gauged. All the cases taken as illustrative were investigated by the sphygmograph and the various forms of irregularity and their mode of production were described. The associations of cases of cardiac arrhythmia were then considered: (1) dyspepsia; (2) syphilis; (3) osteo-arthritis; (4) disturbances of the sense of hearing and naso-pharyngeal affections (illustrative cases were given under this head which tended to show that a reflex from the naso-pharyngeal tract and from the neighbourhood of the auditory mechanism was often a potent cause of cardiac irregularity); (5) influenza (instances were given of special forms of arrhythmia due to the disturbance of the nervous mechanism by this cause); (6) mental disturbances and the effects of severe nervous shock; (7) cases without notable associations (these were parallel with those cases of rapid heart which showed no notable morbid alliances). In the second category were considered ten cases of Graves' disease, in some of which the cardiac irregularity was of the most pronounced degree. It was shown that in such the patient might be perfectly unaware of any irregular movements of the organ and it was also shown that subjective suffering was not in any way correlative with the evidences of arrhythmia. It was urged that the attention of

the subject should never be drawn to his irregular heart. Dr. Sanson submitted that all forms and degrees of irregularity, from the slight to the most pronounced, were to be ascribed to disturbances of the nervous mechanism of the heart. The associations in cases of irregular heart strikingly resembled those in rapid heart. Both such forms of disturbance of the heart rhythm were to be found in cases of osteo-arthritis, in those of aural, nasal and pharyngeal disorder, and especially in Graves' disease. The cases without notable associations might point the lesson that whilst the central disturbance from which the other affections of Graves' disease were offshoots brought about in the majority abnormal rapidity of the heart's contractions, in the minority it induced irregularity. So in many instances arrhythmia cordis might be considered a "forme fruste" of Graves' disease, only it was better to express it that the *ensemble* of the phenomena of Graves' disease was due to the extension from the area of disturbance, which was focally that portion of the nervous system which was concerned with the regulation of the heart's movements. In all such cases, whether manifesting tachycardia or arrhythmia, outbreaks of dyspnoea or of gastrointestinal disturbance—vagus storms as he had termed them—were frequently observed. It seemed probable that whilst sudden overstrain was more likely to produce a tendency to morbid acceleration, the more chronic forms of mental depression tended to be associated with irregularity. When a sudden shock or extensive disease, however, specially involved the afferent fibres of the vagus, pronounced cardiac arrhythmia might be the result.

Dr. B. W. RICHARDSON, while recognising fully the extreme clinical value of the paper, said that his attention had been rather directed to simple intermittency, and he had obtained as many as 400 illustrations of this pulse. When intermittency once began, and it usually commenced after sixty, it was permanent. It was generally due to failure in the sympathetic nerve-supply, though it might depend on irritation of the vagus. As to the effect on the body of irregular cardiac action, it had very little effect provided the patient did not know of it, but it became serious if the patient dwelt on it, and death might then occur from slight causes. There was a modification of the irregular pulse during the course of an acute disease, and always to the disadvantage of the patient.

Dr. MAUDE said that he had had some cases under his care which illustrated the paper. A year ago, in a case of otherwise ordinary Graves' disease, he found a rhythmical irregularity of the pulse, the peculiar characters of which afterwards disappeared, an ordinary rapid pulse remaining. The rhythm seemed to resemble the respiratory phenomenon of Cheyne-Stokes breathing. He had watched a good many cases of Graves' disease, but in only a few was there an irregular pulse. He lived in a district where goitres were common, and had seen quite a hundred during the last five years, and in at least six of them he had found cardiac arrhythmia and acceleration; one or two cases had developed since into typical Graves' disease. Not much attention had been paid to the irregularity of pulse in epileptics. He quoted a case in which an epileptic suffering from late syphilis and irregular pulse died quite suddenly, and at the necropsy nothing could be found to account for it.

Dr. WOAKES desired to speak as to the condition of two patients who had been referred to in the paper. One was a lady who was under treatment ten years ago for deafness and nasal affection who got better, but she returned later, and a cleavage of the middle turbinated bone was found, a part of which had become attached to the septum nasi. Heart perturbation or cardialgia was a common consequent on nasal disease. In a second case the patient was suffering from severe tinnitus, with intense vertigo and some deafness. He found a large mass of granulation tissue in the higher region of the nose on the left side, deflecting the septum. He removed the growth with a galvano-cautery, and found a cleavage of the turbinated bone. After operating on the nose the cardiac trouble got better.

Dr. PASTEUR quoted a case to show the effect of position on the pulse. A woman who had been weakened from an attack of pelvic cellulitis suffered from much depression with extreme palpitation and a week later there was found extreme cardiac irregularity; immediately she lay down the pulse became perfectly regular. Under treatment she improved and the effect of posture on the pulse disappeared.

Dr. RICHARDSON remarked that Dr. Knox of Edinburgh had pointed out that this difference in the pulse between the standing, sitting and lying postures was a purely physio-

logical one. He himself always took his pulse readings in the three positions.

Dr. THOROWGOOD observed that in the pregnant woman there was no difference in the pulse, whether they were standing or lying. The test of elevating the arms in cases of weak heart should be applied with care and caution; he had seen a patient who tried it fall down in a faint and later the same man died suddenly of cardiac disease.

Dr. STEPHEN MACKENZIE referred to the irregular heart which occurred in anæmia, in which there was often a peculiar rhythm, as pointed out by Dr. Wilks. In diphtheria there was a great alteration in frequency of action, together with marked irregularity. He agreed that the prognosis was graver when the patient was cognisant of the malady. He knew of a medical man who had had an irregular heart for twenty years and seemed none the worse for it. He had seen instances where an irregular or intermittent heart had become regular during the course of an acute disease. He quoted a case to show how suddenly rapidity of cardiac action might come on and pass off. In cases of irregularity the trouble often passed off, but in cases of intermittency the condition was generally permanent.

Dr. SOLOMON SMITH doubted if there was a valid reason for drawing a line of distinction between cases of irregularity of hearts which were diseased and those which were not. The symptoms and the causation of the irregularity in the two were precisely the same. Treatment in both, which was directed to external causes of irritation, was more likely to be efficacious than measures aimed at the heart itself. In all cases of irregularity there was a dislocation of stimuli, which made the heart contract arrhythmically; even where the cause was intrinsic it might not be always due to overloading of the heart and need not mean weakening of the heart muscle, even in cases of organic valve disease. This view of the origin of the irregularity would bring the two classes of cases more in line.

Dr. ALLOHIN referred to the cases associated with mental trouble, and asked Dr. Sansom whether in such instances he had found the irregularity associated with a high tension pulse which remained permanently, but was unaccompanied by albuminuria, the heart itself appearing normal; he had seen several such cases. The severity of the symptoms was generally in direct proportion to the acquaintance of the patient with his condition.

Dr. SANSOM, in reply, said that one of the objects of his paper was to insist that cardiac irregularity might be perfectly devoid of really dangerous significance. He thought that nasal and aural troubles were the commonest reflexes which started the cardiac derangement. In the diphtheritic cases it was difficult to eliminate the myocarditis which might be present. Though irregularity often ceased with the onset of acute disease it usually returned after the latter passed away. Intermittency was generally persistent and was serious only to a minority. He had related elsewhere many cases of irregularity coexistent with high tension. He concurred entirely in the view that the irregularities in cases of cardiac disease were ingravescent of a neurotic character on the cardiac lesion and were not part of the disease itself. Many cases of mitral stenosis were accompanied by irregularity, due to an interference with the transmission of nerve impulses between the auricle and the ventricle. The irregularity in typhoid fever was probably due to myocarditis. Fatty degeneration of the heart was not usually accompanied by irregularity, contrary to what was once the accepted teaching. The objects of his paper were to show that cardiac irregularity might co-exist with a sound and good organ, and that irregularity was one of the not infrequent associations of Graves' disease.

### CLINICAL SOCIETY OF LONDON.

*Subacute Pulmonary Œdema occurring above a diminishing Pleural Effusion.—Excision of a Wandering Spleen for Axial Rotation.—Hemiplegia in Typhoid Fever.—Fracture of Lower Jaw with Traumatic Aneurysm.*

AN ordinary meeting of this Society was held on Dec. 9th, Sir Dyce Duckworth, President, in the chair.

Dr. JAMES CALVERT read a communication on a case of Subacute Œdema of Lung occurring above a diminishing pleural effusion. A man aged forty-five was admitted into the Royal Free Hospital on Sept. 22nd, 1891, with pleural effusion. On Sept. 23rd the whole of the left side was dull with fluid; it was aspirated and forty-five ounces of clear yellow serous fluid drawn off, followed by partial expansion

of lung above the fourth rib. The position of the heart beneath the sternum was not altered by the aspiration; it was evidently held by adhesions. Two weeks after the operation the lung above the fourth rib became œdematous, with abundant subcrepitant râles, and profuse expectoration of grey frothy, watery fluid. During these two weeks the effusion had diminished, which was evidenced by the sinking in of the intercostal spaces, by the resonance of the sound side extending to the left of the sternum and by the breath sounds becoming audible at the base behind; the upper limit of fluid could not be percussed out with accuracy because of pleural thickening and adhesions. The œdema persisted for three weeks and then began to decline gradually, so that when the patient left the hospital in January only an occasional crepitation could be heard. He attended as an out-patient for six months and during this time he had no cough, no expectoration, no crepitations, and he gained weight and strength. The temperature after the aspiration was normal throughout. This subacute œdema, evidently different to the acute œdema occurring immediately after aspiration, was not due to an increasing effusion compressing the lung, or to a rupture of the effusion into the lung, or to new growth obstructing the venous return, but was probably due to obstructed venous return in a lung held by adhesions and endeavouring irregularly to expand in presence of a diminishing effusion. Practical point:—These crepitations, limited to one apex and persisting for weeks, were not due to phthisis.—Dr. SAMUEL WEST thought that the case stood almost by itself; he had never seen anything of the kind. What, he asked, was the comparative frequency of acute œdema of the lung? It occurred in only a small percentage of cases of pleurisy. He referred to an instance which was not long ago in St. Bartholomew's Hospital, under Sir Dyce Duckworth. Paracentesis was performed and about two hours afterwards the patient expectorated two pints of fluid. It gave rise to no symptoms because only one lung was involved, and in a short time the expectoration subsided and the patient did well.—The PRESIDENT could not believe that these cases were at all allied to acute œdema, which itself was exceedingly uncommon.—Dr. CALVERT, in reply, said that the colour of the effusion which was drawn off was yellow, whereas the expectoration was grey, like soapy water. Therefore he did not think it could have come into the lung through a crack in the pleura, as some had suggested.

Mr. BLAND SUTTON communicated the details of a case in which he had performed Splenectomy for a Wandering Spleen. The patient, a married woman aged twenty-two, mother of one child, became aware of the existence of a swelling in the left half of the abdomen. In March she was seized with acute pain in the tumour, accompanied by vomiting and diarrhœa. On her admission to the Middlesex Hospital the tumour, which was very mobile, resembled hydronephrosis of a movable kidney, but the diagnosis was eventually reduced to a hydatid cyst of the omentum or a wandering spleen. On March 21st an exploratory operation was undertaken and the swelling proved to be a greatly enlarged spleen, with a twisted pedicle. The pedicle was untwisted and the spleen returned to the left hypochondrium. The patient lost her pain, rapidly convalesced and left the hospital wearing a carefully adjusted belt. Six weeks afterwards the spleen was in its normal position and apparently of proper size. On July 7th the patient came again to the hospital with a return of her trouble; the "lump" had appeared again and she was suddenly seized with acute abdominal pain, vomiting, diarrhœa and hæmorrhage from the vagina. After consulting with his senior colleagues Mr. Sutton advised the patient to submit to removal of the spleen. In order to give some idea of the wandering capabilities of the spleen it might be mentioned that on July 9th it was in the right iliac fossa in front of the cæcum. On July 10th it was in the left iliac fossa, resting on Poupart's ligament. On July 12th it was in the pelvis, its lower end resting on and doubling up the uterus. Splenectomy was performed on July 12th, the abdomen being opened through the scar of the first operation; the incision extended from the umbilicus to the symphysis pubis. The pedicle was twisted through three complete turns and with its distended veins looked like a huge umbilical cord. The pedicle was transfixed and tied in two halves with thin but strong plaited silk and then encircled with a separate ligature for safety. The wound was closed in the usual manner. The patient was treated as after an ovariotomy and recovered without the least drawback. The spleen weighed sixteen ounces, and though of an unusual shape

was in texture quite natural. Observations on the numerical strength and proportions of the blood-corpuscles were made before and subsequently to the operation, and it had been arranged to continue them for some months to come.—The PRESIDENT, while congratulating Mr. Sutton on his excellent result, hoped that the sequel of the case would be reported to the Society. He remarked on the apparent thickness of the splenic capsule, as seen in the specimen; but this was due to its shrinking and preservation in spirit.—Dr. GLOVER asked if anything in the previous history explained the condition found. Was it not possible to have fastened the wandering organ to the parietes?—Mr. SUTTON, in reply, said that Dr. Andrews in the St. Bartholomew's Hospital Reports had collected the histories of a number of cases of axial rotation of abdominal organs. Such cases first came into prominence when a discriminating diagnosis of ovarian tumours began to be made. The spleen was so greatly distended that he feared even to handle it, much more to put a stitch in it. Records showed that it was very difficult to untwist the pedicle, and they demonstrated that the far safer practice was to remove the spleen rather than allow it to remain or endeavour to replace it by external manipulation.

Dr. FRANCIS HAWKINS read notes of a case in which Hemiplegia with Aphasia occurred during the course of typhoid fever, and at the necropsy a thrombus was found in the left auricle and a clot in the left middle cerebral artery; the case was also complicated by purpura and hemorrhage from the bowels. In an analysis of seventeen cases which had been collected from various sources, hemiplegia was found to have been associated with typhoid fever three times in children, the youngest being between two and three years; the remaining cases occurred in adults, most cases at ages between twenty and twenty-five; the oldest patient was thirty. As regarded sex it was much more frequent in males than in females and the period of occurrence was between the third and fourth weeks and during convalescence. In one instance hemiplegia was noticed as early as the ninth day. The right side was paralysed in twelve cases and the left in four. Facial paralysis was also present in some instances. Aphasia was present in twelve instances, being associated in ten cases with right hemiplegia and in two with left. Hemorrhage from the bowels, syphilis and pneumonia complicated some cases. The duration of the hemiplegia was in most instances from ten days to several weeks, but in one case it lasted only three days. Recovery took place in the majority of cases, but the hemiplegia remained persistent in some cases and death occurred in two instances. The cause of the hemiplegia when it occurred late in the disease was thought to be due, as shown in the case recorded, to the formation of a thrombus in the left ventricle giving rise to an embolus, and so hemiplegia in these cases was regarded as a consequence of a cardiac complication. Instances of such a condition in diphtheria and noma vulvæ were quoted. When the hemiplegia occurred early in the disease it was suggested that another cause must be sought, and instances were quoted of hemiplegia being present in cases of pneumonia and phthisis in which no coarse lesion could be found.—Dr. HALE WHITE said that the cause of the hemiplegia was undoubtedly ante-mortem clotting in the left auricle or ventricle, an embolus being then carried to the cerebral vessels. The cases quoted demonstrated the late period at which the blood tended to clot, and showed that a typhoid fever patient was not "out of the wood" when the temperature fell in the third week. The blood was likely to clot in cases in which severe hemorrhage had occurred, these being analogous to the thrombosis in anæmia and also in low-class, badly fed patients. He regarded the hemiplegia as a complication rather than as a symptom, the blood clotting in the left side of the heart instead of in the more common site—the left subclavian vein.—Dr. DIVER asked what line of treatment was pursued as soon as the purpura showed itself.—Dr. VOELCKER asked if there was any evidence of softening as the result of the embolus. He referred to a case of septic endocarditis associated with hemiplegia in which on the cortex of the brain were found distinct purpuric spots.—Dr. LONGHURST inquired if any statistics were extant as to clotting fifty years ago, and he asked if ammonia or other diffusible stimulant might not be the means of preventing thrombosis.—The PRESIDENT said that nowadays the attention of the practitioner was directed too little to the patient and too much to the disease, and in these cases the peculiar needs of the individual should always be thought of.—Dr. HAWKINS, in reply, said that he regarded the hemiplegia neither as a symptom nor as a complication, but as the consequence of a cardiac lesion. No purpuric spots were observed on the brain, but there was some softening.

Mr. WAINWRIGHT read the notes of a case of Fracture of the Lower Jaw associated with Traumatic Aneurysm. The patient, aged twenty-three, was admitted on July 24th, 1889, into Charing-cross Hospital, having been jammed by a descending lift, and sustained a fracture of the lower jaw on the left side together with concussion of the brain. Some days later an abscess formed on the right side and was opened. He left the hospital on Aug. 18th, but returned on the 29th with fresh abscesses formed over the right side of the jaw, which were likewise evacuated. On the 31st he was seized with a sharp pain on the right side of the face and on examination a pulsating swelling was discovered in the parotid region. The house surgeon was summoned and, considering the pulsation to be merely transmitted from the carotid artery, cut into the swelling, giving exit to a small quantity of pus, which, however, was immediately followed by a smart gush of blood, when it was discovered that a traumatic aneurysm had been laid open. Mr. Wainwright was called and he found a second and hitherto unsuspected fracture of the jaw just below the right condyle. The right common carotid artery was ligatured and the wound healed readily, but a fortnight later hemiplegia slowly developed associated with mental weakness culminating in dementia. The mental symptoms subsequently improved to a limited extent.

## OPHTHALMOLOGICAL SOCIETY.

*Kerato-malacia in Young Children.—Panophthalmitis following Lacrymal Abscess.—Probable Rupture of the Optic Nerve.*

AN ordinary meeting of this Society was held on Dec. 8th, the President, Mr. Henry Power, F.R.C.S., in the chair.

Mr. HOLMES SPICER read a paper on Kerato-malacia in Young Children. These subjects were more liable to gangrene of the cornea than adults when their vitality was reduced below a certain level. The gangrene might either be spontaneous or the result of comparatively mild attacks of conjunctivitis. In the late stages of tuberculous meningitis and in infantile diarrhoea the cornea underwent destruction, this being due partly to exposure and partly to insensibility. After measles or whooping-cough, with bronchitis and malignant varicella, where there had been much exhaustion, the cornea was not infrequently seriously damaged by large perforating ulcers. After serious malnutrition the cornea might slough spontaneously, as was not uncommonly seen among nurslings in countries where the mothers practised long religious fasts. In this country it was rare except among the hand-reared who had had insufficient nitrogenous diet. The affection generally attacked both eyes of children from four to nine months old; it began with dryness of the conjunctiva, with patches of froth on its surface and with night blindness; soon the whole cornea became opaque and perforated, the termination being very often fatal. In treatment a principal feature should be the increase of the nitrogenous constituents of food, some meat juice or raw meat finely powdered, in addition to milk for young babies, and cod-liver oil. Locally eserine in the form of ointment should be applied to the eye, with warm applications to the lids. Some of the cases under this treatment made a good recovery; in one case the cornea recovered, although the child eventually succumbed.—The PRESIDENT alluded to the disease as met with in adults, and mentioned a case he had recently seen in a woman completely crippled by arthritis deformans.—Mr. DRAKE-BROCKMANN said he had met with many cases of kerato-malacia in India in times of famine, during epidemics of cholera and not infrequently in association with chronic dysentery. He thought the condition in children was often associated with congenital syphilis. In many cases destruction of the cornea occurred with extraordinary rapidity.—Mr. DOYNE mentioned the case of a child of six weeks in whom, after this condition, the cornea cleared almost completely.—Mr. PRIESTLEY SMITH (Birmingham) dwelt upon the necessity of keeping a careful watch upon the cornea in children and others prostrated by serious illness. The cornea was often exposed during sleep and prone to severe ulceration. Protection of the cornea by a bandage, or adhesive plaster on the eyelids, would often prevent this dangerous complication. Sometimes even union of the margins of the lids was necessary, as in blepharoplasty. He split each lid at its margin, in its long axis (as in Arlt's operation for trichiasis), and brought together the raw surfaces of the upper and lower lids with stitches, without loss of tissue, the results being satisfactory.

Dr. ROCKLIFF (Hull) read the notes of a case of Panophthalmitis following Lacrymal Abscess. The patient,

aged sixty-three, had suffered for thirty years from lacrymal obstruction, but never before the present attack, from abscess of the sac. The suppuration in the lacrymal sac was followed by conjunctivitis, chemosis, keratitis with hypopyon, panophthalmitis and excision of the globe. On examination the whole eyeball was filled with inflammatory products and there had been much matting of the orbital tissues. Dr. Rockliffe also reported the case of a man who had been kicked in the face by a horse, dividing the lower lid close to the inner canthus and splitting the cheek open. The resulting cicatrix produced ectropion. Tweedy's operation was performed, with results quite as satisfactory as in cases in which the deformity was at the outer canthus.

Dr. JOHNSON TAYLOR (Norwich) read notes of a case of Probable Rupture of the Optic Nerve in a young man who, in stooping to pick up kindling wood, struck the right lower eyelid violently against the end of a piece of wood standing obliquely on the floor, with the result of immediate and permanent loss of sight in the right eye. The neighbouring bone was not struck; there was no probability of penetration; the skin alone of the lid appeared to have been broken; no tenderness or swelling of the eyelid or conjunctiva followed and only slight temporary patchy discolouration of the skin resulted. No headache, vomiting or other symptoms ensued; the patient immediately resumed his work and continued it for several hours. When seen for the first time, five days later, the right eye had no perception of light, the direct pupillary reflex was entirely absent; indirect reflex and contraction of the pupil with convergence were normal; movements of globe normal. The appearances on ophthalmoscopic examination were almost nil, and quite inadequate to explain the symptoms. After discussing the possible explanations of the case, Dr. Taylor suggested that the optic nerve had been ruptured either by sudden violent and extreme rotation of the globe or by overstretching, the result of the sudden proptosis produced by the piece of wood being driven in between the eyeball and the lower orbital margin.—

Mr. ADAMS FROST spoke of a case he had seen at Moorfields, in which the stem of a tobacco pipe had pierced the orbit and ruptured the optic nerve. The disc became recognisably atrophied in about a month. The wound through which it entered was so trifling that, unless the stem had remained in the orbit till the patient came under observation, it would have been impossible to say that there had been more than a mere scratch. He thought that in Mr. Taylor's case direct injury to the nerve by penetration offered the more plausible explanation.—Mr. C. WRAY mentioned a patient under his care in whom, after removal of the blind eye, an orbital exostosis was found, against which the nerve might easily have been compressed.—Mr. BULLAR (Southampton) referred to a case similar in many respects to Mr. Taylor's, in which there had evidently been a perforating wound of the orbit.—Mr. TWEEDY gave an account of a man under his care at University College Hospital, in whom a portion of the stem of a tobacco pipe had entered the orbit, damaged the optic nerve, causing blindness, and had remained embedded for two years. The man was unaware that he had received any injury other than a scratch on the eye.

The following card specimens were shown:—

Dr. BRONNER (Bradford): Portable Sterilising Apparatus for Instruments, Bandages and Dressings.

Mr. JULER: (1) Guttate Choroiditis; (2) Cyst of Iris; (3) Pemphigus of the Conjunctiva.

Mr. LAWFORD: New Growth in the Ciliary Region.

Mr. HARTBRIDGE: Intra-ocular Growth.

Mr. FRANK HAYDON: Ophthalmoscopic Atlas for recording Changes in the Fundus Oculi.

Mr. SILCOCK: Recurrent Growth in both Orbits (?Syphilitic).

Dr. A. SANDFORD (Cork): (1) Double Sarcoma of Orbit in an Infant; (2) Gunshot Wound of Eyeball.

## OTHER METROPOLITAN MEDICAL SOCIETIES.

**ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.**  
The sixth annual general meeting was held in the Court-room of Guy's Hospital on Monday, Nov. 21st, at 4.30 P.M. The following gentlemen were elected office-bearers for the Session 1892-93:—President: Sir W. Turner, F.R.S.; Vice-Presidents: John Curnow, Alexander Macalister, and H. St. John Brooks. Treasurer: G. B. Howes. Secretaries: Ambrose Birmingham (Ireland), A. M. Paterson (Scotland), Geo.

Henry Makins (England). Council: Wm. Anderson, Stanley Boyd, D. J. Cunningham, John Cleland, L. A. Dunn, Percy Fleming, Wardrop Griffith, W. P. Herringham, Alexander Hill, Robert Howden, C. B. Lockwood, Clement Lucas, T. H. Openshaw, T. W. Reid, Arthur Robinson, H. D. Rolleston, J. Bland Sutton, Johnson Symington, Arthur Thomson and Bertram Windle. H. J. Waring, M.B., B.S., F.R.C.S., and F. C. Kempson, B.A., were elected Members of the Society, and seven candidates for election were nominated to be balloted for at the next meeting. Mr. Arthur Thomson presented the Report of the Collective Investigation Committee for the session 1891-92. The Treasurer made his report, and stated that the Manuscript Index to the first twenty-five volumes of the *Journal of Anatomy and Physiology* is rapidly approaching completion.—Professor CURNOW exhibited a Parietal Bone with a complete Dentated Transverse Suture; Mr. BLAND SUTTON a Rudimentary Supernumerary Pollex, containing a single conical piece of bone articulating with the trapezium, possessing a basal epiphysis and bearing a nail; Mr. T. W. P. LAWRENCE a series of Abnormal Potuses; Mr. F. G. PARSONS a last Rib in *Hystrix Cristata* mainly converted into fibrous tissue. Papers were read by Professor MACALISTER, F.R.S., on the Acromion Process and on the First Costo-vertebral Joint; by Dr. CARWARDINE on the Supra-sternal Bone in Man; by Mr. ARTHUR THOMSON on a Theory of the Development of the Skin in relation to Pigment. Professor CUNNINGHAM, F.R.S., contributed a paper on the Delimitation of the Regions of the Abdomen. The proceedings and papers will be found *in extenso* in the January number of the *Journal of Anatomy and Physiology*.

**EPIDEMIOLOGICAL SOCIETY.**—At a meeting on Nov. 16th, Dr. F. J. PAYNE, on retiring from his tenure of office as President for the past year, took as his subject that of Tuberculosis as an Endemic Disease. The communicability of phthisis or tuberculous disease through the inoculation of the specific poison, as distinguished from other and ordinary inflammatory products, first enunciated by Villemin in 1835, though the validity of his conclusions had been impugned, was, he said, clearly formulated by Cohnheim, who in 1881 placed the doctrine of its specific nature on a basis as firm as that of small-pox and other diseases of which the actual contagium vivum was as yet undiscovered, till soon afterwards Koch, by the isolation of the bacillus tuberculosis, its artificial cultivation and inoculation experiments, confirmed and extended by numerous other investigators, gave to the etiology of tuberculosis a certainty attaching to no other human specific disease. Dr. Payne then spoke of the characteristics of this group of diseases, its long and insidious incubation and progress, and the absence of any tendency to self-extinction of the morbid process, its endemicity &c. The evidence derived from a study of the tubercle bacillus in artificial cultures was wholly against the supposition of an ectogenetic origin. The observations of Buchanan and others established beyond doubt the connexion of phthisis with dampness of sites and defective subsoil drainage, but the disease might flourish on the best drained soils. Overcrowding and deficient ventilation were potent predisposing causes and instances were given in support of this contention. Dr. G. Cornet's researches did not support the hypothesis of universal diffusion of tubercle bacilli and their inevitable inhalation by all persons. Dr. Cornet failed to detect them in dust collected out of doors and in the medical wards of hospitals and other places unless phthisical patients were present, but the sputa of such patients were highly infectious. The only other mode of communication worth consideration was that through the use of milk from phthisical mothers and animals. The communicability of tubercle therefore was so incomparably feebler than that of small-pox &c. as scarcely to entitle it to the position of a contagious disease. The broad fact of heredity was universally admitted, though when the parasitical nature of the disease was recognised a recoil took place and heredity was explained to mean no more than the inheritance of a greater susceptibility than was possessed by others. The hereditary transmission of or tendency to tubercle and its manifestation in later life were well marked in cattle. Maffen's experiments on the inoculation of hen's eggs with the bacilli of fowl tubercle ("fowl-cholera," as it was absurdly called) were remarkable. The bacilli did not develop in an egg, but becoming incorporated with the embryonic structures developed the disease in the young chickens. Among cattle tubercle was so general that some persons were inclined to look on it as originally a bovine disease, since communicated

to man in various ways, especially by infected milk. But it was suggestive of its endemicity that while unknown among wild animals, nearly all monkeys, ruminants and rodents brought into the Zoological Gardens sooner or later died of tuberculosis, a fact that was explicable only on the hypothesis of localisation and contagion.

**HARVEIAN SOCIETY OF LONDON.**—At the meeting on Nov. 3rd, Dr. Cheadle, President, in the chair, Mr. MALCOLM MORRIS showed a case of Rodent Ulcer. It commenced as a hard pimple at the inner angle of the eye; it does not appear how many years ago, but it did not ulcerate until 1870. In October, 1888, it measured one inch by one inch and a half; had attacked the periosteum and bone; was scraped and the actual cautery applied. At present a large cavernous ulcer occupies the space between the eye and nose and extends for some distance on to the cheek. No operative treatment is proposed on account of the man's age and ill health, but it is being treated locally with a solution of resorcin (thirty grains to the ounce) and opium internally to relieve the pain.—Dr. STEPHEN MACKENZIE read a paper on Dermatitis Herpetiformis. He defined it as a cutaneous neurosis characterised by the multiformity of its manifestations, which may consist of erythematous, papular, vesicular, bullous and urticarial eruptions, and may appear concurrently or consecutively, being usually attended with pigmentation of the skin; a grouping of vesicles is the most characteristic feature and present in most cases at some part of their course; it is usually attended with great itching and burning; it runs a chronic course with exacerbations or relapses and intervals and usually terminates spontaneously, but may end fatally; it is attended with some, but usually not great, disturbance of the general health; it affects both sexes at all ages, but is most common in the middle period of life; in women it is often connected with pregnancy, but may occur independently of it. He gave notes of twelve cases of the disease observed by himself; one of the patients, a woman aged forty, with very characteristic eruption being exhibited. The vesicular and bullous varieties had in his experience been the most common, and in nearly all a grouping of vesicles on the herpetic plan had been present at some period of the disease. All parts of the body are liable to be attacked, but in most cases the palms and soles escape. The disease is most liable to be mistaken for vesicating and bullous erythema and pemphigus, but is to be distinguished from these by its polymorphic character and severe pruritus. As regards its pathology, he thought it was either a peripheral neuritis or a functional neurosis. As regards treatment no internal remedy exercised a certain curative influence, but arsenic sometimes succeeded, and where it failed to cure it often controlled it. Of local treatment soothing applications failed to give more than temporary relief, and sulphur, as recommended by Duhring, was most deserving of trial.—Dr. RADCLIFFE CROCKER related his experience of this disease and showed a number of photographs and water-colour paintings illustrating its various points. In the main he agreed with Dr. Mackenzie as to the pathology and treatment of the disease.—Dr. J. J. PRINGLE had seen twelve indubitable cases of the disease among about 6500 skin patients at the Middlesex Hospital in the last four years and two in private practice. Of the hospital cases no less than seven were examples of the type described by Unna as hydroa puerorum, and fully accorded with his description, especially as regards the presence of pain rather than of itching and of papulo-vesicles rather than bullae. Two cases had proved fatal: one was a lady aged eighty, who died of marasmus after being afflicted for eight months; while the other began as a hydroa gestationis, lasted seven years and the patient died of peritonitis following perforation of the ileum, which as well as the cæcum presented numerous ulcers considered as internal manifestations of the disease. Throughout the case there had been indications of marked implications of the alimentary mucous membrane.—Dr. SAMUEL WEST related his experience of the disease, and showed photographs and drawings from patients.—Dr. MACKENZIE briefly replied.—At the meeting on Nov. 17th (Dr. Cheadle, President, in the chair) the Clinical Pulse Manometer was exhibited, an instrument designed to show in ounces the degree of compressibility of the pulse and thus to give some recordable measure of the pulse tension. When endeavouring to estimate the pulse tension with the fingers it is necessary to use three fingers. If a considerable amount of pressure is required to stop the pulse, it is said to be of "high tension;" if very little pressure is sufficient, it is called a "low tension pulse." The instrument is designed to measure the pressure

exerted by the proximal finger. It requires some care and practice in using, but given that the results are far more accurate than those obtainable by the finger, though like these they require to be checked by the other signs of pulse tension.—Dr. WALTERS had used Dr. Batten's manometer for some months and thought it a very valuable instrument. He found that the pulse tension in health varied between seven and thirteen ounces, the average being about ten or eleven ounces. He had found it as low as five ounces in a perfectly healthy and active man. In disease the lowest tension he had met with was three ounces and the highest was twenty ounces.—Mr. BUCKSTON BROWNE read a paper on the Treatment of (so-called) Impassable Urethral Stricture. He pointed out the dangers often encountered by the use of fliform guides, and he laid great stress upon the importance of avoiding all perineal incisions into the urethra. He showed that occasionally these incisions did not heal, and then the state of the patient was deplorable. All could be done, even in the very worst cases, safely and efficiently through the urethra by a surgeon who thoroughly relied upon his manipulative power, if he was in addition convinced, not only as Syme taught, that where urine came out an instrument could always be put in, but that in all cases, whether urine issues from the external meatus or not, an instrument could always be passed through the penis, through the stricture and into the bladder. Secondly, Mr. Buckston Browne maintained that when once an instrument had been passed a surgeon who had confidence in himself should be able immediately to replace it by one a size larger, and so on until there was room for the introduction of a Civiale's urethrotome. He also insisted that if an instrument could be passed through the orifice of a stricture by looking, as in Wheelhouse's operation, it could be surely passed by feeling, therefore there was no need to open the perineum and expose the patient to all the risks of a perineal wound. In reply to questions Mr. Buckston Browne said that as far as the condition of the kidneys was concerned the results after his operation were quite as good, if not better, than after any other form of urethrotomy. He thought it quite possible to leave the urethra and tap it again in passing the small steel sounds; indeed, the same thing might occur in external urethrotomy. In his own practice he had never seen septicaemia. In a case of retention if anaesthesia was necessary and the patient was prepared to remain in bed for some little time, he would proceed to perform his operation at once. He thought that the scar tissue in cartilaginous strictures might be absorbed to a surprising extent provided a free flow of urine could be ensured. He would abolish Syme's and Wheelhouse's operations on the ground that they were never necessary.

**HUNTERIAN SOCIETY.**—At the meeting on Nov. 23rd, F. Gordon Brown, M.R.C.S., President, being in the chair, Dr. HINGSTON FOX showed two cases of Myxœdema in women aged forty-two and fifty-four years respectively. Both were about to undergo treatment, the one with fresh sheep's thyroid glands administered by the mouth, the other with a powdered extract obtained from the glands.—Dr. STEPHEN MACKENZIE then read a paper on Urticaria, having first showed a boy aged fourteen who had suffered from urticaria pigmentosa all his life. The disease was now quiescent, but there was no difficulty in raising well-marked wheals surrounded by red areas on scratching his skin with the finger nail. Dr. Mackenzie placed the nervous centre of the reflex mechanism in the dense plexus of fine nerve fibres in the superficial layer of the corium. Local irritation was a frequent direct cause of urticaria. In other cases this was indirect, as from the ingestion of mussels; here probably a poison entered the blood and affected the nerve plexus in the skin. Urticaria also attacked mucous membranes and was thought to give rise to asthma. A case of urticaria following the rupture of a hydatid cyst was described, a rare and singular phenomenon. It had also followed parturition and the passage of a uterine sound. Cases illustrating rarer forms of urticaria were then detailed: (1) Urticaria hæmorrhagica, in a boy aged two years, after eating fried Dutch plaice; (2) giant urticaria, in a man aged thirty-seven, after working in a hot vat containing some chemical; (3) chronic urticaria, in a boy aged fourteen, following chicken-pox; (4) urticaria pigmentosa, the case already shown. The treatment consisted in the discovery and removal of the cause and the mitigation of the effects.—The PRESIDENT alluded to urticaria following sea bathing and to the frequency of the disorder when erysipelas was pre-

valent.—Dr. PYE-SMITH doubted whether the disease could be regarded as a peripheral reflex phenomenon. Local irritants might act by their direct influence on the blood-vessels themselves and the indirect causes probably acted reflexly through the cord. A true relation existed with acute articular rheumatism. There was also a close connexion between urticaria and erythema, so that he would regard them as varieties of one disease.—Dr. F. J. SMITH described an attack of urticaria from the bite of a jelly-fish.—Dr. NEWTON PITT referred to two cases in which urticaria was always brought on by contact with ipecacuanha.—Dr. MACKENZIE, in reply, fully agreed as to the connexion with rheumatism, although numerically such cases bore a very small proportion to the whole. His theory of the nerve centres in the skin was based merely on clinical evidence and therefore quite open to question.

**SOCIETY OF MEDICAL OFFICERS OF HEALTH.**—At the meeting on Nov. 21st, Mr. SHIRLEY F. MURPHY, in delivering the inaugural address on his election to the office of President for another year, traced the history and the expansion of the Society from its origin among the metropolitan officers to its extension to the provinces and the formation of branch associations. As he had last year followed the genesis and development of the medical officer of health and the beneficial influence exerted by this order in educating the architect, the engineer and the public, he now asked whether, with all our progress; we might not learn by comparing, not our own experiences only among ourselves, but the practices of other countries in those matters especially which we, rightly or wrongly, ignored or deemed of little moment. He then spoke of the necessity of more regular State inspection of our food-supply. In Germany they required assurance that all meat was fit for food; here we assumed it to be so unless the contrary happened to be shown by conspicuous changes. The cattle market and slaughter houses of Berlin were simply perfect and were the pattern of those in other German cities. The procedures involved employed nearly 200 officials, including a score of clerks, the remainder being veterinarians, microscopists, inspectors &c. All condemned carcasses and offal were disposed of on the premises, fat boiling, glue boiling &c. being carried on there. Small fees were charged for each operation and fodder provided at cost price. To exercise an equally strict control of the meat-supply of London an army of nearly 1500 officials would, he imagined, be required. He then referred to experiments on animals with tuberculous flesh more or less cooked and the results obtained which were positive in proportions varying from 0.0 to 47.7 per cent. with the degree of tuberculation and the thoroughness of the cooking. The percentage of tuberculous cattle brought to market varied greatly in different places. Mr. Schmidt in Alsace found the proportions vary from 0.3 to 3.1 in different Rhenish towns, but in North Germany Ostertag found from 10 to 26 per cent. In Berlin the average was 4 per cent., but in districts where cows were largely fattened for the butcher it was from 8 to 12 per cent. It might be said that things were better in this country, but almost the only evidence we had was the recent inquiry of the new Board of Agriculture, from which it appeared that the percentage of animals affected was 12.22 of bullocks, 16 for cows in calf, but only 1 for calves sent to the butcher and 1.5 for bulls. In the London markets the average was 15.5, or one animal in every six, and doubtless many more among carcasses were disposed of more or less surreptitiously. He was strongly of opinion that though we might dispense with the microscopical examination for trichinosis, which employed the majority of the eighty microscopists at Berlin, all animals should be slaughtered and dressed in public abattoirs only, under the eyes of fully qualified inspectors and that the inspection should next be extended to dead meat imported from abroad or sent in from the provinces. Then dairy farms ought to be brought under effective veterinary control. A large dairy company which supplied the greater part of the milk consumed in Copenhagen kept a staff of seven veterinary surgeons solely for the systematic inspection of the cows on the various farms with which they had contracts. Our Cow-sheds and Dairies Order was practically useless, since the only diseases recognised were those scheduled in the Contagious Diseases (Animals) Act. In conclusion Mr. Shirley Murphy stated that the whole question would be seriously taken up by the Society with the co-operation of the Medical Officers of Health of those towns where meat inspection was efficiently carried out.—Dr. SISLEY then read a paper on the Prevention of Cholera in England, asking whether we were prepared for a recrudescence of the epidemic on the Continent next year,

and whether our abandonment of quarantine, which most persons held to be, like free trade and protection, a question settled for all time, was a wise policy? However this might be, he would remind the Society that its abandonment in 1849 by the General Board of Health was founded on an assumption which all now admitted to be utterly false—viz., that cholera was caused by atmospheric influences; and that the absolute exclusion of all infected persons and things even if practicable would be of no avail to keep the epidemic from our shores. Surgeon-General Cornish had called attention to the injustice and unwisdom of imposing heavy expenditure on the port sanitary authorities for the benefit of the country at large, since the probability was that persons bringing infection from France or Belgium would not manifest the disease until they had reached inland towns in perhaps remote parts of the kingdom. He concluded by asking the Society to pass a series of resolutions for the completion of the sanitary survey, the granting of new powers to the port sanitary authorities, the transfer of their special burdens to the imperial exchequer, the provision of a pure water-supply to London &c. After a short discussion it was decided that some of these questions being set down for future discussion and others open to difference of opinion, the Society should not commit itself to any abstract resolutions until time had been given for their deliberate and careful consideration.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY.**—At the clinical evening, held on Dec. 2nd, F. Swinford Edwards, F.R.C.S., President, being in the chair, Dr. RAYNER BATTEN exhibited a Clinical Pulse Manometer.—The PRESIDENT showed a Femur with Subperiosteal Sarcoma after amputation at hip-joint in a woman aged twenty-six. The limb was removed by the Furneaux Jordan method, and primary union had taken place throughout the entire length of the wound on the ninth day, and the patient left the West London Hospital well within the month.—Mr. RICHARD LAKE showed a boy aged six on whom he had operated for Cholesteatoma of the Mastoid Antrum, which had penetrated the posterior fossa. Uninterrupted recovery followed.—Mr. WILLIAM STEER showed: 1. A case of Friedreich's Disease, which commenced at the age of ten years by difficulty in walking, especially in the dark and on going upstairs. At seventeen walking was impossible and now at the age of twenty-four the patient is quite unable to stand. There is incoordination of muscles of both upper and lower extremities and head and neck, loss of knee-jerk and plantar and cremasteric reflexes, hesitating speech and lateral nystagmus. One brother had died of the same disease. 2. A case of Idiopathic Muscular Atrophy in a lad of fifteen, commencing at the age of twelve. There was no marked atrophy of the face muscles and labials were well pronounced. The muscles of the upper extremities were much wasted. 3. A case of Myxœdema in a male.—Mr. KEETLEY showed: 1. A case of Inguinal Hernia complicated with Undescended Testicle. An operation for radical cure had been performed and the testicle brought into the scrotum, the tunica vaginalis testis being held there by a temporary suture uniting it to the adjacent tissues of the thigh. 2. A case of Subcutaneous Suture of the Patella.—Mr. BRUCE CLARKE showed a case for which he had performed nephrography nine months previously. The operation had been undertaken because the symptoms were severe, resembling those of renal colic. In his experience these cases yielded by far the best results after operation.

**GLANDERS.**—On the 9th inst. the representatives of several of the London omnibus companies, together with others concerned in the management of horses, waited upon the General Control Committee of the London County Council for the purpose of trying to induce that body to reconsider its decision not to compensate owners of glandered horses slaughtered to prevent the spread of this disease. The committee agreed to reconsider the question.

**SURGICAL AID SOCIETY.**—The report read at the annual meeting of the friends of this useful society, held on the 9th inst., was a highly favourable one, showing enhanced interest in its work, and an augmenting increase in its income. During the past year an average of 210 patients had participated weekly in its benefits, the total for the year being 10,887. No less than 111,938 of the suffering poor had been helped by this society from the time of its commencement in 1862. The usual votes of thanks to the Lord Mayor, who presided, and the officers of the society terminated a very satisfactory meeting.

## Reviews and Notices of Books.

*Public Health Problems.* By JOHN F. J. SYKES, B.Sc. (Public Health), M.B. Edin., Medical Officer of Health for St. Pancras, London, and Honorary Secretary of the Incorporated Society of Medical Officers of Health. Illustrated. London: Walter Scott, Limited. 1892.

WE have been much gratified by our perusal and examination of this book. It is not by any means a mere compilation or a dry record of details and statistics, but it takes up essential points in evolution, environment, parasitism, prophylaxis and sanitation bearing upon the preservation of public health and discusses them in a suggestive and reflective spirit. It fulfils its title of "Public Health Problems" by the manner in which its author approaches and treats the various subjects and conditions influencing health. It is not an encyclopædic handbook or digest to be referred to for figures, details and rules of procedure; its value lies in its statement of principles and reasons, from a consideration of which the reader should be led to make his own deductions and shape his course accordingly. We may make our meaning clearer, perhaps, by way of illustration. A gifted and highly cultured lady was sensible that time had somewhat weakened her fine memory, and she was rather sensitive on the point. One day, when one of her daughters had gently brought some dropped stitches of information to her recollection, the old lady shrewdly retorted that "she had not forgotten them, but had assimilated them long ago." It is not so much in reading a certain class of books that one requires to recollect exactly the information as to assimilate it and record the impression it made at the time. After an introductory chapter in which the ideas to be conveyed within the limits of the volume are briefly outlined and allusions are made to the problems of life and health, personal and public, the author proceeds in Part I. to the internal and external influences upon health, and begins with heredity, following it up with chapters on physical influences and chemical media and biological agents. Part II. is devoted to the consideration of communicable diseases, Part III. to defensive measures against these, and Part IV. to urban dwelling. Heredity is a somewhat intricate and difficult subject, but it is lucidly as well as ably discussed in the chapter devoted to its consideration. The aim of hygiene is to ascertain, first of all, the range of modifiable conditions affecting health, and then to determine the measures and processes by which these conditions can be modified in favour of the individual or community. The limit of adaptation of the individual is much sooner reached than the limit of modification of the environment. The chapter on biological agents briefly indicates the practical principles underlying our recent advances in this direction, and the necessity of studying, in connexion with human pathology, the conditions affecting all organic life and their influence upon the health of man. The subject is considered in more detail in relation to communicable diseases, their causation, dissemination, modifications and parasitism. Under the head of urban conditions the author does well to advert to some points, for example, in regard to the provision of cubic space, which are occasionally apt to be overlooked or disregarded in practice. The amount of space to be provided will manifestly depend upon many circumstances, a thousand cubic feet of air being ample under certain conditions and quite inadequate under others. The importance of superficial and wall space should always be borne in mind in relation to site and the facilities for the ventilation and lighting of a room or building. A man may be suffocated in a crowd with the sky above him, and whether he is in a spacious cathedral or a handbox ventilation is still essential. The growing evils of town life through defective air, light and space are

forcibly dwelt upon and the remedial methods by which these may be overcome or minimised are pointed out. We cordially agree with the author's conclusion of the whole matter to the effect that public opinion is but the expression of public education, and that this is the key that must unlock the doors of ignorance and let in the light and air of hygiene equally as fully as other human knowledge. The knowledge acquired by education must be trusted to bring home to a nation that the acquisition of health means the acquisition of wealth. The information, as well as the writing and the reasoning are of a kind not readily adaptable to the extracting of passages, although we had marked several with the intention of discussing them and of affording some samples of the author's style and method of treating the subject. We must content ourselves, however, by saying that the book is scientifically and well-written, and that its author has evidently been anxious to gather the latest and best information on public health problems so as to obtain for himself first of all, and afterwards to aid others in getting for themselves, a good grip of the subjects with which he deals.

*Anæsthetics; their Uses and Administration.* By DUDLEY WILMOT BUXTON, M.D., B.S. London: H. K. Lewis. 1892.

THE new manual on Anæsthetics in Lewis's practical series is a well-written and instructive work and will amply repay perusal. The author claims for it that it is a practical manual rather than a disputatious treatise, and this is exactly the kind of book that is most useful to the student. There are several passages in it which might be studied with great advantage not only by the junior students but also by the full surgeons to a hospital, and notably one in which Dr. Buxton calls attention to a practice which has over and over again been condemned in the columns of this journal—viz., that of a surgeon allowing his dresser to administer the anæsthetic instead of procuring the services of a recognised anæsthetist. He says: "It is surprising that surgeons who have witnessed the attempts of novices to give anæsthetics should hold any view save that no one is capable of safely giving any anæsthetic unless he has been carefully taught and has obtained considerable experience."

The practice of anæsthetics is still making strides in a forward direction, and this book is very nearly up to date; but two points omitted, which will doubtless be noticed in the next edition, are the great improvement in Junker's inhaler by Mr. Carter Braine, and Mr. Rowell's practice of admitting air during the administration of  $N_2O$ . This latter is a distinct advance, because it proves conclusively that the anæsthesia produced by the inhalation of  $N_2O$  is not due to asphyxia, but is a purely anæsthetic condition; the gasping respiration and the discolouration both being absent owing to the admission of air, time is given for the  $N_2O$  to produce its true anæsthetic effect. On this point the author remarks that "nitrous oxide gas possesses well-defined anæsthetic properties, which appear to be quite distinct from the asphyxial symptoms frequently accompanying its administration."

The improvement in Junker's inhaler by Mr. Carter Braine has entirely done away with the danger of administering the fluid chloroform itself, or even its spray—an accident which may happen when Junker's inhaler is tilted during the operation. Only the vapour of any anæsthetic used can be administered, whatever the position of this inhaler may be. The chapter on the history of anæsthetics will be found interesting alike to the student and the general practitioner. Chapter IV. is devoted to ether, but the headline of this chapter is unfortunately chosen, being "Sulphuric Ether—Anæsthetic Ether," and this may lead the student to conclude that the ether used for local anæsthesia is also used for inhalation. On turning to the chapter on local anæsthesia

we find that the author notes that this ether is a specially prepared one, being a mixture of anhydrous ether with an equal part of hydride of amyl; but he omits to caution his readers that this ether mixture if inhaled may kill by suddenly stopping the heart's action, a result which may follow the administration of chloroform. It therefore follows that anæsthetic ether should never be used for inhalation. The author does not mention that the specific gravity of anæsthetic ether for local purposes is 0.656°, while that for inhalation is 0.720°. Dr. Buxton criticises the Ormsby inhaler rather severely, but we have not found his objections to it to hold good in practice. We find under the heading "Dangers and Accidents of Ether Inhalation" the author states that when asphyxia is imminent "the head must be thrown back and the tongue drawn forward; by this means respiration may be induced to start; but failing this, tracheotomy must be performed." But we should prefer laryngotomy, an equally efficacious and easier operation.

In the pages dealing with the physiological action of chloroform Dr. Buxton gives an interesting account of the Hyderabad Commission, and, in common with most English anæsthetists, does not agree with the conclusions the Commission arrived at. To quote his own words: "Various European and American persons of authority traverse this by pointing out the fact that in temperate climes deaths from chloroform inhalation occur in the practice of the most skilled anæsthetists, and that such deaths have been repeatedly observed to have resulted from primary heart failure."

## CHRISTMAS BOOKS.

### NEW BOOKS FOR YOUNG PEOPLE.

THE large assortment of new books for young people, which we have received from the various publishers furnish examples of such general excellence, high character and instructive nature as to make one wish to be young again. The faculty of imagination is perhaps more active and more appreciative in youth than in adult life. Besides affording food for this faculty the Christmas books this year are extremely rich in accounts of heroes, deeds of valour and historical incidents. Compared with dry text-books of geography and history there is no schoolmaster who will not allow that the most reliable and the most lasting knowledge of these subjects is to be obtained from books such as are provided for young readers at this season of the year; and it is with pleasure that we proceed briefly to note such works as have come under our observation. Novels with a moral are not wanting, but they are of a very polished kind. Fairy stories are plentiful and very varied. Tales for young children are told with spirit-stirring interest and excellent taste, and we are pleased to note that, without exception among the large number of books submitted to us, ghost stories are conspicuous by their absence; they are apt to provoke morbid fear and timidity in young children.

BLACKIE & SON (Limited), 49, Old Bailey, E.C. — This firm of publishers have submitted to us some excellent new books for boys. Foremost amongst these is "Beric the Briton," from the pen of G. A. Henty. The volume will be eagerly sought after by boys who are anxious to know something of life in this country at the period of the Roman invasion. The book abounds in interesting and instructive historical facts and thrilling national pictures of the Druids and of the ancient kings and queens of Britain, such as will stir up much chivalry, courage and manliness—not to speak of national pride—in the heart of any boy who reads the work. "Condemned as a Nihilist" is from the same pen, but the story is laid in Russia. The geography of Russia, life in the prisons and the treatment of Russian prisoners, together with the perils and adventures attending an attempted escape, will afford to boys many an interesting hour. A third book, still

from the same pen, is called "In Greek Waters." Here life in Greece on the shores of the Mediterranean, with all the surrounding scenery and picturesque descriptions of historical places, together with a history of the recent Greek War of Independence, will also be found highly instructive. "The Thirsty Sword" is the title of a story from the pen of Robert Leighton, describing the Norse invasion of Scotland which ended in the famous battle of Largs, where Alexander of Scotland defeated Haco of Norway, the battle which put an end for ever to the Scandinavian supremacy in Scotland. "The Captured Cruiser," by C. H. Hyne, is a sea tale which boys will read with much delight, as also "An Old-time Yarn," by Edgar Pickering. For girls, "The Heiress of Courtleroy," by Anne Beale, and "A Very Odd Girl," by Annie E. Armstrong, will be found to be suitable gift books.

SKEEFINGTON & SON, 163, Piccadilly, W. — "Olga's Dream," a nineteenth-century fairy tale, is novel in respect of its matter and of its illustrations. Norley Chester has endeavoured to work up in the form of a fairy tale some of the wondrous scientific inventions and political improvements which have taken place during the present century, and a very pleasant fairy tale it makes. These have been very humorously illustrated by Mr. Harry Furniss and Mr. Irving Montague. Having all the interest of a fairy tale pure and simple, it is certain to amuse children; it is at the same time impossible for anyone to read it without profiting by the suggestions, references and amusing touches which decorate the pages of this excellent volume. "Soap Bubble Stories" for children, by Fanny Barrie, is an excellent specimen of a book for the more juvenile *clientèle*. Describing it in the words of the authoress, it consists of "Some white froth whipped up in a fairy basin, the soap being the imagination and the pipe a humble black pen." The stories are amusing, and the book well illustrated. Another tiny volume of a different class from this same firm is "The Schoolboy's Little Book," perhaps too learned and too good for most schoolboys.

CHATTO & WINDUS, 214, Piccadilly, W., have furnished us with an excellent selection of story books for Christmas. Before alluding to these, however, we may note *The Antipodean*, a new journal, which is edited by George Essex Evans and John Tighe Ryan. We welcome this new publication, the object of which is to form a literary link between the mother country and those of her children who live beyond the seas. If one were to judge of the literary abilities of Antipodeans in general, from the style and excellence of the articles in this first number it would be impossible for any candid critic to criticise Australian writing adversely. A feature of the first number of the journal is the photographic illustrations of the authors of the various articles. "Bimbi" is a story book which all children will read with delight. The stories are from the pen of "Ouida," the well-known writer, and they are of exceptional merit, and will be highly appreciated by all who read them. The stories of the French dog "Moufflou" and of "The Little Earl" are specimens of children's tales of an excellent character. We next take up "The Fate of Herbert Wayne," written by E. J. Goodman, and dedicated in memory of thirty years' friendship to Dr. James Peddie Steele, himself a brilliant author and erudite scholar. The plan on which the book is written renders it very fascinating, the plot is well sustained, the writing is facile and manly, and, though treating of a psychological subject, there is nothing morbid throughout the whole work. A book of an interesting character is "Corinthia Marazion," a novel by Cecil Griffith. It is a clever work, interesting as a story and full of admirable character studies; pictures and scenery are graphically drawn, and the whole book is well constructed. One of the most taking of the whole group submitted to us is from the pen of Walter Besant, entitled "Verbena Camellia Stephanotis." *The*

*Gentleman's Annual* contains a complete novel, entitled "The Loudwater Tragedy," by T. W. Speight.

LONGMANS, GREEN & Co., 39, Paternoster-row, E.C., forward to us a copy of "The Green Fairy Book," edited by Andrew Lang. It is a typical Christmas present, handsomely bound and printed, tastefully edited and beautifully illustrated, forming a companion volume to those which have already appeared as "The Blue Fairy Book" and "The Red Fairy Book." It contains a selection of the best fairy tales from all countries—France, Russia, Italy, Scotland, England and China—and affords a remarkable illustration of how all these nations agree in their liking for fairy tales. The following quotation may be taken from the editor's preface: "You see in the tales how a boy who is kind to beasts and polite and generous and brave always comes best through his trials, and no doubt these tales were meant to make their heroes kind and unselfish, courteous and courageous." That is the best possible comment which can be given to any book, and we endorse it in the case of Mr. Lang's work. "Another drawing-room book is the "Biography of Slander," edited by Edna Lyall.

T. NELSON & SONS (London, Edinburgh and New York) have submitted to us the following volumes, which of their kind are well worthy of that energetic firm. There is a peculiar appropriateness in the appearance this year of "With the Admiral of the Ocean Sea," by Charles Paul Mackie, in which the author portrays with much realism, and necessarily therefore with great interest, the never-to-be-forgotten discovery of the New World by Christopher Columbus. Original sources of information have been consulted; the dramatic incidents in the career of the hero are appropriately dealt with; and the attitude of his powerful patrons, as ungrateful at last as they were slow-witted at first, is duly treated. As a book calculated at once to instruct and interest both the young and children of a greater growth we have pleasure in recommending this volume.—"In the Days of Chivalry." E. Everett Green deals with the stirring period in which our Black Prince taught our brethren across the Channel that the residence of the Normans in Britain had not deteriorated the race. Disinherited brothers, after many adventures, come to "their own again," and exhibit not only a manly prowess, but the higher virtues of magnanimity and forgiveness.—Of "Martin Rattler," which has long been a favourite among boys, we need say no more than that Robert Michael Ballantyne, in the new edition of this deservedly popular book, will continue to amuse and instruct boys for many years to come. To make the past live and to instil interest and vitality into the dead bones of ancient history, there is no more effectual method than the "historical novel." It is not necessary that such should deal only with the prominent political personages of any age. The "history" of a period includes the experiences of all classes. In the thirteenth century the baron was always an arbitrary person. In "The Robber Baron" of Bedford Castle, the authors provide a careful study, historical and topographical, of the social conditions of the period. "The old, old story" has its place here, while the reward of virtue and punishment of vice will commend the tale to every well-conditioned reader, young or old.

SMITH, ELDER & Co., 15, Waterloo-place, S.W., have sent us the following Christmas books: "Hours in a Library," by Leslie Stephen, new edition with additions, in three volumes. We could not wish a better companion to a library than this well-known work. It consists of a series of essays on the works of the following among other authors: De Foe, Richardson, Pope, Scott, Hawthorne, De Quincey, Sir Thomas Browne, Horace Walpole, Dr. Johnson, Crabbe, Hazlitt, Disraeli, Fielding, Wordsworth, Macaulay, Brontë, Kingsley, Sterne, George Eliot, Carlyle and Coleridge. The papers are eminently analytical and critical, and on the whole we think the works

of the various authors are treated with great fairness and keen insight.—"The White Company," by A. Conan Doyle, is a stirring romance by this well-known author. The interest of the story is sustained to the end and the narrative throughout is highly instructive.—"Grania: the Story of an Island," by the Hon. Emily Lawless. New edition. This is a capital story of Irish life in one of the islands of Aran, Galway Bay. The picture given here of the peasants in some of the remote districts of the west of Ireland shows a keen perception of the habits of the people and considerable literary skill in making from such rough material so readable a book.—"The Slave of the Lamp," by Henry Seton Merriman. New edition. A very clever and well-written story and thoroughly enjoyable from beginning to end.—The new edition of "A Woman of the World," by F. Mabel Robinson, adds fresh interest to a very pleasant everyday story.

T. FISHER UNWIN, 11, Paternoster-buildings, has submitted to us some copies of "The Children's Library." "Nutcracker and Mouse King," a translation from the German of Hoffmann, by Ascott R. Hope, to which is added a translation by the same author of Hoffmann's "Educated Cat," will be read with avidity by many children. The philosophic faculty of the German finds expression even in nursery tales, and the gradual development of the perceptions and conclusions of a cat has an interest for others than the feline race.—"Once Upon a Time" is a collection of fairy tales translated from the Italian of Luigi Capuana. The sixteen complete little stories of which the volume consists will instruct and interest children and parents alike. Many of the illustrations, which are by Mazzanti, enhance the value of the book.—"Finn and his Companions," by Standish O'Grady, revives memories of the sturdy race who, possessed of pristine virtues in the days of the Romanised and degenerate Britons, impressed their influence upon a considerable portion of these islands. The illustrations are by J. B. Yeats. These Ossianic tales, circling as they do round the personality of St. Patrick, should at Christmastide prove very acceptable reading. The paper and printing of this series are all that could be desired.—"A Splendid Cousin," by Mrs. Andrew Dean, issued by the same publisher, is one of the handy pseudonym library rendered famous originally by the appearance of Mademoiselle Ixe. It would not be fair on reviewing a novel to sketch the outline too fully, but the reader will find much to interest in this story. Whether the conduct of the "Splendid Cousin" might not have been rendered still more noble by a less conventional termination may be a matter of opinion.—"Colette," by Philippe Saint-Hilaire, is a very readable rendering of a very old theme. The imprisoned Princess—the isolated fair one—wasting her beauty in the unrecognised seclusion of an old chateau, like many similarly situated young ladies, keeps a diary—natural, artless, charming. The liberating Prince, of course, arrives in due course, Parisian, but honourable, and all die happy. The armchair in the smoking-room would have its attractions increased by the prospect of dreaming over "Colette."—"Daddy Jake the Runaway" and other Stories, by "Uncle Remus" (Joel Chandler Harris), will make a very suitable Christmas present. It is printed on good paper, is well illustrated and abounds in "plantation" humour. The jingle of rhyme adds greatly to the merriment of the nursery, and in "Another Brownie Book," by Palmer Cox, issued by the Century Company, New York, and T. Fisher Unwin, London, both rhyme, matter and illustration will provoke the mirth of the rising generation.

CASSELL & Co. (London, Paris and Melbourne) provide a rich supply of handsome Christmas volumes. It is a triumph of literary production that for a sum of nine shillings a solid, well-printed and well-illustrated volume like "Cassell's Family Magazine" should be possible of purchase. Families dwelling in remote parts of the country, where libraries may not be easy of access, would find in this

volume material, instructive and entertaining, which would occupy them for many weeks.—It is only the privilege of the few to have, or to have had, it in their power to haunt the great artistic collections of Europe, or to have had opportunities of drinking in the refining influences of cultured and æsthetic surroundings. Not only by such, however, but by all interested in the cultivation and diffusion of "taste," *The Magazine of Art*, issued by the same enterprising firm, must be regarded as a missionary of art, for it brings within the reach of all by carefully written critiques and skilfully executed engravings, well-known and teaching pictures and sound and valuable instruction. "*The Historic Houses of the United Kingdom*" is a charming descriptive, historical, pictorial account of some of the splendid Abbeys and Castles in this country. The descriptions of Floors Castle and Cawdor Castle will interest readers beyond the Tweed, while the account of Kilkenny Castle will delight Irish readers. It is to the English reader, however, that the lion's share of this gorgeous literary feast no doubt naturally falls. To visit and admire the castles themselves will be the natural sequence of a perusal of this beautiful and artistic book.

#### OTHER SEASONABLE PRODUCTIONS.

*Mona MacLean: Medical Student.* A Novel, by GRAHAM TRAVERS. Three volumes. Edinburgh and London: William Blackwood and Sons.—This is a capital book, just sufficiently medical to give it special interest to medical readers, but not of so professional a character as to diminish its interest for the public. The pictures are drawn with the touch of an artist, and those portions of the work which delineate Scottish life and character have a special attraction by reason of their aptness. A noteworthy feature of the novel is the variety of scene and place which it affords. The conversation throughout the work is easy, flowing and well sustained. The plot is of the slightest kind, and it is worthy of remark that, as is usually the case in novels written by lady authors, the men in this volume are either heroes or "jolly good fellows." We are able to speak very favourably of the book as a healthy, well-written, and effectively-told tale.

*McEwan's Phonographic Magazine.*—We welcome the first appearance of a new magazine devoted to phonography edited by so able an exponent of the "winged art" as Mr. Oliver McEwan. Everything which tends to promote ease, legibility and rapidity of writing is highly valued by shorthand writers. Nothing will promote this so much as accuracy of outline and proper formation. In these respects *McEwan's Phonographic Magazine* may be taken as a model, and when some practice has been attained in the art of lithographing the characters, and of arranging the matter, these qualities will be the more appreciated. On the whole the editor may be congratulated on the success of his venture, and we hope that he will always adhere to his promise to provide "a magazine which can be recommended by teachers to their pupils without any fear of corrupting their phonographic morals." We regret to observe the extent to which the spirit of criticism, to which the epithet "captious" is not in all cases inapplicable, has been developed on the last page of this new publication. Such criticism does not beget friends and we question its wisdom.

*The Medicine Lady.* By L. T. MEADE. 3 volumes. London: Cassell and Co. 1892.—It is not surprising to find the episode in modern medicine known as the "Koch treatment" taken advantage of by the novelist, for indeed the history of that startling discovery, the manner of its promulgation and the furore it excited in all quarters of the globe, were very novel, if regrettable, departures from the sober course of therapeutics. It is around the discovery by a young enthusiastic physician of a cure for consumption that Mrs. Meade has woven a story of

much interest and of marked power. To be sure the topic in question is not one that usually forms the groundwork of a romance; disease and its treatment are hardly pleasant subjects for fiction; but we may credit the authoress with dealing with them skilfully, and one finds in her work not a few sketches of character which are typical enough, together with some home truths concerning the "arts" of medical practice that are hardly overdrawn. On the other hand, the opening scenes, in which the highly neurotic heroine appears in the capacity of a probationer nurse in a children's hospital, are by no means as realistic as they might be. Whilst doubting the utility of works of this class, we do not refuse to admire the construction of the plot, which we may leave our readers to ascertain for themselves.

*The Dawn of the English Reformation; its Friends and Foes.* By HENRY WORSLEY, M.A. Cheap Edition. London: Elliot Stock.—The history of religion in its various forms and guises, with the illimitable transformations which these forms undergo in the lapse of time and under the influence of theological teachers and in some cases of fanatics, must always be of interest to the reflecting mind, even when the subject is regarded simply from the standpoint of the philosopher. The question, however, is a very wide one, and is for the most part outside the region of investigation to which a medical journal necessarily devotes itself. Nevertheless, a few words may be said respecting the scope and character of Mr. Worsley's book. It is divided into six chapters and deals respectively with the condition of the religious world in England before the period of the Reformation; the classical revival at Oxford and Cambridge, with an account of the work and writings of the men who were most prominent in that revival; then follows a record of the part taken by Tyndale (by the translator of the Scriptures) in the Reformation; the separation from Rome in the sixteenth century, and finally the passing away of mediævalism. The fact of the complete extinction of this phase of religious observance may, by the way, be open to question. These matters are learnedly and intelligently set forth and, so far as we are in a position to judge, the volume forms a trustworthy history of the events connected with the rise and progress of the Reformation in England.

*Diaries &c. for 1893.*—The presence on our office table of a batch of diaries for the year 1893 reminds us to take note of the provision made by account-book publishers to supply for the ensuing twelvemonth the requirements of literary men, merchants and others. Amongst publications of this order which demand commendation are those of Messrs. Charles Letts and Co., which for variety and ingenuity leave nothing to be desired. Thus we have the "Improved" (interleaved) "Diary," containing the information usually included in almanacks; a "Diary" specially adapted for note-taking; another for cash entries; a "Day on a Page Diary," enclosed in a neat case; a "Tablet Diary"; a "Scribbling Diary"; and a "Blotting-pad Diary," which provides space for a month's notes at a glance. All these are handy and useful.—Charles Letts and Co.'s "A B C Medical Diary and Visiting List" is published jointly by the above firm and Messrs. Burroughs and Wellcome. The form in which this edition appears presents no great departure from that adopted in former issues of the same diary. There is, however, an addition in the shape of "Excerpta Therapeutica," containing, in an alphabetical arrangement, a list of the principal drugs in general use, both pharmacopœial and extra-pharmacopœial. Also in this issue is included a list of signs which will be useful as an aid towards making the recorded entries complete.—Finally, we have "Letts' Medical Diary," published by Messrs. Cassell and Co., Limited, one specimen being issued in silken covers, and the second in pocket-book form. These are old favourites, and need no further commendation.

# THE LANCET.

LONDON: SATURDAY, DECEMBER 17, 1892.

SINCE the vacation the Gresham Commission has been largely occupied in taking evidence with regard to the various views held by persons interested in the question of the higher University education in London. This has been in many respects quite discordant and often, from what we hear, superfluous. We understand that some of the professors in the Faculty of Science at King's College are still expected to give evidence on the reassembling of the Commission after the Christmas holidays. The Rev. Dr. WACE and Sir GEORGE YOUNG will also be asked to meet the objections that have been raised in evidence against the granting of the Gresham Charter before the hearing terminates. It is believed that the Commission is also desirous of having some reconstructive scheme placed before it by the University of London before the sittings are concluded. A Committee of the Senate, including Professors HUXLEY, THORPE and RÜCKER, has heard the views of the Executive Committee of the Association for Promoting a Professorial University in London (on which are the same three Professors), Sir HENRY ROSCOE and Professor WELLDON being the spokesmen. The possibility of a compromise between the views put forward by the Association, and the traditions of the existing University, has at once led to the resignation of Professor KARL PEARSON, who was the originator of the professorial scheme. Professor HUXLEY has put forward his proposals in a recent letter to *The Times*, on the rough notes of which his evidence before the Gresham Commission was based. They ran as follows:—

“Do not venture to ask for all I want, but for as much as it seems possible to get on the way to that.

“Suggestions tentative and open to modification.

“(a) Retain title and prestige of University of London; reorganise it in such a manner as to secure general uniformity and efficiency of work with freedom and elasticity. In short, unify without fettering.

“(b) Make the institutions which contain technical schools of the theology, law, medicine, engineering and so on into colleges of the University. Let these examine their own candidates for degrees, under conditions determined jointly by them and the Senate of the University; and present such as they declare fit to the University for *ad eundem* graduation.

“(c) Deal in the same way with institutions giving adequate instruction in the other categories of University work—if they so please, or let the University examine.

“(d) Provide ample means for instruction in the modes of advancing natural knowledge and art, either in material connexion with the existing University or in particular colleges.

“(e) Professoriate to have large but not preponderant representation in Senate, and wide, but not exclusive, influence in regulating instruction and examination in accordance with the general aim at unification.

“(f) All State and municipal contributions, private endowments and University fees for instruction and examination to be paid into a University chest. All professorial staff and current expenses (save in cases that may be reserved), to be paid out of the University chest; also building and fitting

expenses where there is no sufficient endowment of a college. The payment of the professorial staff to be primarily regulated by the kind and amount of the work done for the University, not by number of students.

“(g) No bar to be placed in the way of anyone who desires to profit by any description of University instruction. If after trial he does not profit, time enough to exclude. Value of exclusion as disciplinary measure.”

We need not further discuss whether these views were those of the original promoters of a professorial scheme; in any case it is clear that they are altogether opposed to the views of Convocation and every tradition of the University of London. They will, however, be strenuously supported by an influential section of the Senate of the University, and may form the basis of the constructive scheme which that body will place before the Commission. But the annual Committee of Convocation has also been considering a draft outline of a scheme to be submitted to Convocation at its meeting on Jan. 17th next. This scheme deviates but little from former schemes put forward by Convocation, except in containing more definite proposals for the establishment of a University professoriate. Convocation is to retain its existing powers, rights and privileges, and even to extend them a little. But the professors in their proposals definitely urge that Convocation is not, as at present, to have a veto upon the action of the Senate. We think the Senate will hardly be able to make any compromise between these two irreconcilable positions, and we foresee that grave difficulties will arise when it has to choose on which horn of the dilemma it prefers to be impaled. But in all these schemes the claims of the London medical students for degrees on a fair standard are ignored. We understand that these claims will again be brought forward at the meeting of Convocation, but we anticipate that they will be refused by the votes of the other faculties in Arts, Science and Laws. Even after the report of the former Commission, and the judgment of the Committee of the Privy Council, London graduates cannot apparently appreciate the absolute necessity for the institution of a lower but fair standard for medical pass degrees, and they will run every risk, even to the formation of a second University, rather than give way on this point. It is therefore particularly opportune that this subject should have been brought before London practitioners on the 8th inst. by the Metropolitan Counties Branch of the British Medical Association, and that strong and clear resolutions affirming it should have been passed and ordered to be forwarded to the Royal Commission and to the Lord President of the Council. In the Gresham Charter the views of the London medical teachers were so fully adopted that less recognition in any new scheme which may be recommended by the Commission will hardly prove acceptable to the teachers or be just to the students.

AFTER a long hearing, extending over eight days, before Mr. Justice GORBELL BARNES and a special jury, a verdict has been returned upholding the validity of the will made by Miss ELLEN ROE whilst she was a lunatic, so found by inquisition, and an inmate of a registered hospital for the insane. This lady was born about 1824, and was sixty-six or sixty-seven years old when she died. It appears that when she was between thirty and forty years of age she became addicted to alcoholic intemperance, and such was the effect of the bad

habit upon her mind that she had to be placed in a lunatic asylum at Northampton, whence she was transferred to the care of an uncle. In 1884 she was again placed in the asylum, having been found a lunatic on inquisition, and from that time until her death in December, 1891, in the sanatorium at St. Ann's Heath, she remained a "Chancery lunatic" for the most part under asylum supervision. The substantial question that arose at the trial was the testamentary capacity of the deceased lady at the dates, September and October 1891, when she executed a will and a codicil, which were propounded by her brother, a legatee, as the last will of his sister. Mr. NIX and another executor under former wills of the deceased claimed that if the court pronounced against the documents propounded by the plaintiff, it ought to decree probate of a will executed by the deceased in the year 1889. Mrs. SPARKS, a sister of the deceased, pleaded that the documents were not duly executed, and that at the time of their execution the deceased was not of sound mind; and she prayed for a decree of intestacy.

The executor under the documents propounded by the plaintiff was the medical superintendent of the sanatorium, who is a beneficiary under them to the extent of £1000 in the event of their being admitted to probate. He, however, renounced the executorship. The deceased died in December 1891, two or three months after having executed the will in question. In the month of May 1891, the medical superintendent, in his official capacity, certified to the Master in Lunacy that the deceased was then "still of unsound mind"; but in his evidence before the court, as given in *The Times*, he gave it as his opinion that it was doubtful whether, when Miss ROE was admitted to the sanatorium as a Chancery lunatic, medical men could have been got to testify that she was of unsound mind; that he was almost certain a medical certificate to that effect could not have been obtained in the next month; and that at that time, and after, he regarded her as sane. He saw no objection to her executing the testamentary papers of 1891.

The testatrix appears to have been anxious to leave a sum of £1000 to the Archbishop of Canterbury, and a similar sum to the Lord Chancellor in view of their supporting the will; but we have the gravest doubt as to whether, if she had done so, the Lord Chancellor, the legal custodian of all lunatics, would have felt himself either bound or able to accept the money willed to him by a Chancery lunatic circumstanced as Miss ROE was.

Coming to the evidence, we have referred to the fact that the medical superintendent of St. Ann's Heath Sanatorium failed to discover insanity or testamentary incapacity in Miss ROE, and his opinion is borne out by that of his subordinates, a lady-companion and a clerk, who had both come to the conclusion that the deceased was quite sane. The former testified that Miss ROE "was excitable and took dislikes to people, but she always gave reasons for doing so, and as far as witness had an opportunity of knowing, those reasons were good ones. She never thought Miss ROE in the least insane."

Apart from the evidence given by the staff of the sanatorium, we fail to find that any of those who had official relations with Miss ROE as an asylum inmate had any doubt as to her insanity and testamentary incapacity. The superintendents of the two other asylums in which she had resided

and the legal and the two medical Chancery Visitors in Lunacy gave definite and explicit evidence on these points; and the sum and substance of that evidence was stated by Sir J. CROFTON BROWNE as follows: In his opinion "Miss ROE was competent to make a will as far as giving lucid and accurate instructions, and as far as clearly apprehending the facts of her disposal of property went, but she was constantly dominated by insane antipathies and delusions which involved the persons who, in the course of nature, had claims upon her. He distinguished between a mere dislike and a belief that an injury had been inflicted. Now, although Miss ROE was pressed again and again to mention any act of cruelty or neglect by her relatives she never did so, but repeated in a vague way that they were her enemies, that they had treated her very badly, and that she could never forgive them. She laboured under a monomania of suspicion."

No doubt her two sisters, to whom she left nothing by her wills of 1891, had incurred some amount of her resentment by having become, in the first place, the petitioners in the inquisition proceedings, and, afterwards, the committee of her person and estate, but this cannot be regarded as an unnatural or unkind position for them to take up, whilst it is by no means unusual for undoubted lunatics to dislike or hate their committee. But it is poor encouragement for loving and devoted relatives to take up their natural and proper position as guardians under such circumstances, if they have to do so at the risk of having their reasonable expectations displaced in favour of strangers, by the process of legalising the testamentary mental operations of a person suffering from delusional insanity.

In his summing-up, Mr. Justice GORELL BARNES dwelt with emphasis upon the judgment delivered by Lord Chief Justice COCKBURN in "*BANKS v. GOODFELLOW*" (5 Q.B., 149), and he quoted as follows from that authority: "It is essential to the exercise of such a power (of making a will) that a testator shall understand the nature of the act and its effects; shall understand the extent of the property of which he is disposing; shall be able to comprehend and appreciate the claims to which he ought to give effect, and, with a view to the latter object, that no disorder of the mind shall poison the affections, prevent his sense of right, or prevent the exercise of his natural faculties; that no insane delusion shall influence his will in disposing of his property and bring about a disposal of it which, if the mind had been sound, would not have been made. Here, then, we have the measure of the degree of mental power which should be insisted on. If human instincts and affections, or the moral sense, become perverted by mental disease; if reason and judgment are lost and the mind become a prey to insane delusions calculated to interfere with and disturb its functions, and to lead to a testamentary disposition due only to their baneful influence, in such a case it is obvious that the condition of testamentary power fails, and that a will made under such circumstances cannot stand." We are quite willing to accept this constructive statement of the degree of mental power necessary to establish the existence of testamentary capacity. For we hold that the existence of insanity does not of necessity imply the testamentary incapacity of the individual; and we regard it as most material to the question, that the condition of mind should not be dealt

with apart from the character of the dispositions made in their relation to rightful claims; or, in other words, as in the deliverance just quoted, that no insane delusions shall influence the testator's will in disposing of his property or bringing about a disposal of it, which, if the mind had been sound, would not have been made.

The testamentary relationships of insane and morbid minds with their environments bristle with difficulties, and there are points in the case of "ROE v. NIX and Others" which are exceptional, not to say unique. We cannot help expressing our feeling that in consequence of disease there was some amount of mutilation or dislocation of the natural affections and instincts in the case of Miss ROE.

We are well aware how unwilling juries are to interfere with the rights of even lunatics to execute a valid last will and testament, and to dispose of their property as they may desire—and very properly so. But we confess that we should not have been surprised to find that in "ROE v. NIX and Others" the verdict of the jury had gone to uphold the weighty and independent medical and official testimony that was produced with a view of establishing the insanity and testamentary incapacity of the deceased lady. In any case, whether, in September and October, 1891, Miss ROE was or was not of sound mind and capable of executing a valid will, we hold strongly the opinion that it is quite wrong and should be made illegal for any superintendent of an asylum to derive benefit from a will executed by any person whilst under his detention and care upon a certificate of insanity or as a lunatic so found by inquisition.

THE question of "uplifted hand" versus "kissing the book" has now, thanks to Dr. GORDON HOGG, passed into what may be called the "acute stage." It will be interesting and perhaps profitable to look back upon what has been the nature of the incubative period (to use again the medical metaphor) of this now burning question. Although it is one which concerns everyone who may be called upon to take an oath in our courts of law or elsewhere, and is therefore a general question, there are two very cogent reasons why it should have been taken up by those who represent the medical profession. Its members are summoned as witnesses much more frequently than those of the other two professions or, indeed, of any other body of men. A large proportion of those who obtain medical and surgical diplomas soon become resident medical officers to hospitals, infirmaries and dispensaries. Among their duties is that of giving evidence at inquests more or less frequently and also in the police, the sessions and assize courts. There are few practitioners who have not at one time or another been called into the witness-box while those who hold appointments as analysts, professors or lecturers on forensic medicine, police surgeons &c. are frequently required to give evidence. It follows from this that most of the members of the medical profession are thoroughly acquainted with the practice of our courts of law with regard to the manner in which the oath is administered. As comparatively few are Quakers the oath is taken by the greater proportion, and this is done by kissing a copy of the New Testament, or of the

Pentateuch by those who are of the Hebrew religion. As the medical man is generally the last witness he has the spectacle of seeing the book kissed by a very mixed class of previous witnesses which naturally suggests ideas the reverse of pleasant. In THE LANCET of March 13th, 1886, page 527, a letter appeared from Dr. HARKNESS of Derby. In it he stated that having to give evidence in the Divorce Court before the late Mr. Justice BUTT he objected to kiss the Testament proffered to him on the ground that two of the previous witnesses were notorious prostitutes and that he might incur a risk of infection. His remark appeared to amuse the judge and some of the counsel, though others upheld his objection. Eventually, at the suggestion of the judge, he kissed the open pages instead of the cover, but, as he truly observed, this still involved the handling of an unclean book while the pages might also have been pressed by unclean lips. And this brings us to the second reason for noticing this apparently, but not really, trifling matter. That infection may be conveyed in this way is undoubtedly within the bounds of probability; hence as medical journalists anxious to safeguard the health of all witnesses, whether medical or lay, all jurors, and all who may be required to take an oath, we felt bound to support Dr. HARKNESS'S objection. His letter was followed by several others. One writer suggested kissing the thumb or holding the book near but not against the lips. Another suggested the use of a cover made of some material which would not absorb infectious matter. A third and better suggestion was that witnesses should swear with uplifted hand, as has been always the practice in Scotland from time immemorial. The subject dropped for a while, to be revived again in 1888. In THE LANCET for that year, vol. i., page 586, it was suggested that in the then proposed Oaths Bill, providing affirmation instead of oath for those who had no religious belief, provision should be made for those who preferred to swear with uplifted hand instead of kissing the book. Whilst we were thus suggesting this on medical grounds others were doing the same for religious reasons, to relieve Presbyterians in Ulster from the necessity of kissing the book and to enable them to swear with uplifted hand like their brethren in Scotland. The coincidence is at least remarkable. Ultimately the Act was passed with the now famous fifth clause:—"If any person to whom an oath is administered desires to swear with uplifted hand, in the form and manner in which an oath is usually administered in Scotland, he shall be permitted so to do, and the oath shall be administered to him in such form and manner without further question." So that all that is necessary to secure this more cleanly form of adjuration is that the person (whether juror or witness) shall express his desire to be so sworn.

This Act was passed on Dec. 24th, 1888, but attracted so little notice that its clauses, and particularly the fifth, were wholly unknown to us until a correspondent called our attention to them in a letter which was published in THE LANCET of Jan. 23rd, 1892, p. 235. While lamenting this oversight it would appear that it has been shared by those who have less excuse—solicitors, coroners, magistrates and their clerks. More than one witness claiming to be sworn with uplifted hand has been refused, the responsible official being ignorant

that this refusal was illegal. Now that the Act is nearly four years old it is imperative that it should be known to all whom it may concern, such ignorance being unpardonable. Dr. GORDON HOGG has not only taken care that all jurors and witnesses appearing before him shall be made fully acquainted with the privilege given them by this Act, but has also impressed upon them the risks which they incur by the older and more general mode of oath-taking, and has succeeded in making, so far as his court is concerned, the newer and less objectionable mode the rule and not the exception. Some medical witnesses giving evidence before other coroners have claimed to be sworn with uplifted hand, and their claim has been at once admitted.

So far this is very well, but much more remains to be done. It is perfectly right that medical witnesses should set the example and show the public that they have the courage of their opinions. But it is equally right that other witnesses and jurors should lose no time in following the example. The average Englishman who appears as juror or witness is ready enough to grumble at any grievance, but much less ready to aid in its reform. Those who have complained of having to kiss the book—and their name is legion—have only themselves to thank if they continue to do it. Silence in this matter will signify consent, and it must not be assumed hastily that all who preside in our courts of law will pioneer this reform so boldly as the newly elected coroner for West Middlesex has done.

And this leads to a very important question. The Act says "*In the form and manner in which an oath is usually administered in Scotland.*" There the oath is administered by the presiding judge, sheriff, sheriff-substitute or baillie, who stands, holds up his right hand, directs the witness to hold up his, ungloved, and to repeat after him the form of words, which differs from that used in England, being in the first, not the second person, and with some slight variations, as follows: "I swear by Almighty GOD as I shall answer to GOD at the Great Day of Judgment that I will tell the truth, the whole truth, and nothing but the truth." Do the words we have talicised refer only to the uplifted hand, or do they involve an exact imitation of the Scotch form? If so, are our judges, recorders, magistrates and grand juries all aware of this obligation should jurors and witnesses claim to be sworn in this way? Are they ready to see the crier or usher who now administers the oath gradually disestablished and to take upon themselves the duty now performed by him?

Leaving this question to those more competent to answer it, we must in conclusion express our satisfaction that this very desirable reform has made so decided an advance. Setting aside for a moment the risk of infection, the indiscriminate handling and kissing of the same book by a succession of jurors and witnesses is, to say the very least, a nasty practice which cannot be defended when there is ready to hand an equally solemn and less objectionable alternative. So far witnesses and jurors have endured that which they believed could not be cured; but it is impossible to suppose that when they are made fully acquainted with the fact that they have a choice they will hesitate to use it, or to feel any doubt as to which mode they will prefer.

## Annotations.

"Ne quid nimis."

### THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE annual meeting of the constituents of the Hospital Sunday Fund was held on Tuesday afternoon at the Mansion House. The Lord Mayor, the Right Honourable Stuart Knill, presided, and displayed a hearty interest not exceeded by any of his predecessors in the success of the Fund of next year. The attendance was good, and the resolutions adopting the report of the Council, continuing the laws of its constitution, and filling up vacancies in the Council caused by death or otherwise, were unanimously adopted. A few reasonable questions were put from the body of the meeting, such as show a healthy interest in the cause. One of these had reference to the number of letters allowed to particular congregations. The gentleman who spoke thought that the poorer contributing congregations should have more letters of recommendation than those which sent large sums to the Fund. The answer was very easy, that the Council by its laws was entitled to *letters of recommendation equal to half only of what might be claimed by annual subscribers*, and that such letters were always given in fit cases on the application of ministers or others representing such congregations, one minister, representing one of the poorest congregations in the East-end, testifying that he had never made an application without its being responded to. The point is that letters of recommendation are given not to any congregation, rich or poor, but to the Council for distribution. Though the total receipts of this year are less than they were last year, the difference is explained chiefly by the large donation of £5000 given by the Duke of Cleveland. The satisfactory feature of the collection is that it represents thirty more contributing congregations than last year. Indeed, the number of these steadily increases. There have now been twenty yearly collections, beginning in 1873, the year of Sir Sydney Waterlow's mayoralty. In that year there were but 1072 contributing congregations, or 669 less than in the present year. There can be no doubt that the Fund has a strong place in the confidence of the churches and of the community generally and that it draws together, as no other cause does, men of all creeds. It is a grand thing while men are still conscientiously unable to worship in each others' churches that they are able to meet on such a platform as this to perform one of the first duties of pure and undefiled religion. June 11th is fixed for the Hospital Sunday of 1893. A report of the meeting will be found on page 1405.

### THE LOCAL GOVERNMENT BOARD AND CHOLERA PROSPECTS.

WE understand that, in view of the prospect of a renewal of cholera next spring and summer, the Local Government Board have decided on an increase in the staff of their medical inspectors, and that the appointments, which are mostly of a temporary character, have already been practically determined on. A cholera survey will forthwith be instituted, much on the lines of the survey that was carried on during the European epidemic of 1884-86. An alteration has also been made as to the Orders under which the importation of rags and bedding into this country from infected places is prohibited, the object being to relieve, as far as possible, a number of trades in which various woollen, linen and other articles, technically described as rags, are largely used for the manufacture of cloth, rugs, paper &c. The principal changes effected by the new Order go to admit all articles that are clean without any restrictions

whatever, and of removing the prohibition as regards other rags provided they are properly disinfected at the ports of arrival. If such disinfection is found practicable, it will be proper to maintain it with respect to other diseases than cholera; for if there is one disease which is easily communicated by old torn-up garments which constitute so large a proportion of the rags used in paper mills, it is small-pox—a disease which has again and again broken out amongst rag-sorters employed in these and other mills and manufactories.

#### SICK NURSING.

Few things are more remarkable in the present day than the great interest now being taken in the important function of nursing the sick. The recognition of the value of this work is becoming more and more manifest in all classes, from the Queen upon the throne to the humblest housewife. Nursing is an art which has escaped from the rule-of-thumb method formerly practised by the Sairey Gamp school and has entered upon a career fit to be undertaken by educated and refined women. The fourth annual report of the Scottish branch of the Queen Victoria Jubilee Institute of Nurses now lies before us, and the success of its efforts towards mitigating the pain and misery accompanying the sick bed is extremely gratifying. The appreciation shown by the recipients of the intelligent ministrations of these angels of mercy has created an increasing demand for their services, so that ampler accommodation has had to be provided by an extension of the Home in which nurses are housed and trained. In Edinburgh and Leith during the year for which the report is issued, 1969 cases have been nursed and 40,999 visits have been paid. The amount of distress alleviated and comfort imparted by the efforts of such attendants on the sick it would be impossible to estimate. Amongst the various purposes to which charitable aid can be applied none is of more value and urgency than that of nursing the sick.

#### THE PREVALENCE OF SMALL-POX.

WHILST the small-pox epidemic at Warrington continues to decline, the abatement is not so great as was hoped. In the week ending Dec. 10th twenty-four fresh cases were reported; and Mr. Gornall is still able to state that no one revaccinated fourteen days before developing small-pox has contracted the disease. He also adds that all the fatal cases in children have been amongst the unvaccinated. On the other hand, the new attacks are mostly in houses where antecedent cases have occurred and where vaccination, whether primary or secondary, has been neglected. Some 12,000 people have been revaccinated, but this is only one-fourth of the population. The demand for vaccination is lessening with the diminution of small-pox, and some of the stations for its performance will in consequence be closed. The number of patients suffering from small-pox in hospital was 139 at the end of last week, and it is assumed that ample hospital accommodation now exists. In Leeds the epidemic prevalence is still maintained; fifty-six cases were in hospital last week, and eight fresh attacks were heard of. Cases or deaths have freshly occurred at Liversedge, Nelson, Sedgefield (where the disease has broken out in a common lodging-house), Keighley, Otley (where the prevalence seems to be abating), Runcorn, Scarborough (where it is proposed to erect a hospital outside the town in the rural district in opposition to the terms of the Public Health Act, under which the sanction of the authority of the latter district ought first to be obtained), Hipperholme and Lightcliffe (from which places the patients have been removed into the Brighouse Hospital), Northallerton, Golborne and Derby. In the latter borough four cases appeared last week, three of them occurring in patients alleged to be unvaccinated; all four cases were at once removed to the town isolation hospital. During the same period nine attacks were reported from Oldham, four from Chadderton, twelve from

Manchester, nine from Liverpool, besides cases from Halifax, Birkenhead, Wakefield, Middlesbrough, Leicester and a few other towns. In the metropolis a marked increase in the amount of small-pox has taken place, and over thirty patients are now under treatment in the hospital ships belonging to the Metropolitan Asylums Board.

#### THE INTERCOLONIAL MEDICAL CONGRESS.

OUR New Zealand correspondent writes:—"By special wire from Sydney as this mail leaves we learn that the Medical Congress has received an invitation to hold its next session in Maoriland. The invitation has been unanimously accepted. Mr. Batchelor of Dunedin has been elected president, a well-deserved compliment paid him by his New Zealand brethren, for he is of long standing among us and is of high professional reputation. We have in this beautiful country a rich store of natural wonders to show our Australian brothers, and we can promise them that we will do all in our power to make their visit a pleasant one. It is impossible to visit the various sanatoria of this marvellous land without being struck with their immense value from a medical standpoint, and the time has now arrived when the fame of the hot springs, situated in various parts of the colony, attracts tourists from all parts of the earth. New Zealand offers many inducements to those seeking a pleasant holiday or those in search of health; and I trust the medical profession generally in Australia will grasp the opportunity now offered them of visiting New Zealand and seeing for themselves a country which excels in natural beauties any other in the world."

#### THE EFFICACY OF VACCINATION RESTATED.

OUR attention has been called to a letter addressed to a provincial journal—the name of which has not been furnished with the extract forwarded—published in a district where small-pox has lately been very prevalent. It is a letter which, in its sensible and moderate language, should appeal to every thinking member of the community, and we trust it will be especially weighed and appreciated by those who know the writer—for he must be well known. He is a Catholic priest, and his ministrations have during the epidemic brought him in contact with some hundreds of sufferers from small-pox. He writes, he says, in no spirit of controversy and with "no qualifications except ordinary powers of observation," and this is his testimony. 1. That controversy about the merits of vaccination should be kept distinct from the merits of vaccination laws, just as temperance and drastic liquor laws are not of necessity linked together in point of desirability. It is the public weal that must govern law making. 2. That some constitutions are impervious to small-pox infection. 3. That a single vaccination in some persons suffices for life, whereas in others re-vaccination is necessary, perhaps more than once; but although the period of absolute protection conferred may be of limited duration, it has in all, or nearly all, an "unquestionable modificatory power." He adds that he has never seen a re-vaccinated small-pox patient. 4. His personal experience is that the mortality among unvaccinated patients is treble (if not quadruple) that among vaccinated. 5. That there is a "vast difference between what the unvaccinated patients have to go through, compared with the vaccinated ones. . . . The majority of the former who recover only escape by a hair's breadth, while their vaccinated neighbours are having a comparatively easy time of it." 6. The vast preponderance of medical opinion in favour of vaccination. There is no such consensus for most other prescriptions. 7. As to the risk of vaccination, it is "not so great as when you go to the station and take your child to Leeds or Manchester." He has seen hundreds of children vaccinated and no bad results; and in one case shown to him he was not satisfied that it was clear from the fallacy, *post hoc ergo propter hoc*. "There is always an element of

danger in powerful remedies." Father Patrick Mulcahy—which is the name of this discerning writer—concludes by saying that he himself has been vaccinated four times in forty-two years, and he advises and implores his friends to vaccinate and revaccinate. Although there is hardly a point raised in this letter which is not perfectly familiar to the medical profession, and although some of the statements—e.g., as to relative mortality of the two classes—may be considerably under the mark, yet it is well in these days of "leagues" and "commissions" to bring into prominence the simple truth as it has appeared to the mind of an intelligent observer whom the most pronounced anti-vaccinationist can hardly dare to charge with those aspersions which are so freely bestowed on the medical profession in this matter.

#### A LAUDABLE UNDERTAKING.

A VERY considerable service is done by anyone who points out means by which the sources of everyday worries can be materially lessened. The other day we had an opportunity of inspecting an institution which, it seems to us, will well serve this very useful end. It is housed in an old-fashioned country house, near Caterham, in Surrey. There are around the house, and at the disposal of this institution, twelve acres of land. Nine of these are meadow land, and the rest gardens, poultry yards &c. Close to the house stand its stable, dairy, cow-house, and, in short, the ordinary surroundings of a farm-yard. Besides the usual offices, the house contains ten bedrooms, and three or four sitting-rooms, all well furnished. The purpose which this institution is intended to serve is one which interests a very large number of people, for it aims at the proper training of young women in the details of household management. A sensible woman, no matter what may be her station in life, will always greatly desire for herself, and for other women, that intimate knowledge of household affairs which goes so far to make a happy home. Girls marry and then too often find themselves obliged to try to manage a household without any clear ideas of how to do it. That much and great unhappiness results from this source is a matter of everyday experience. In this Surrey farm-house at Caterham girls are taught, by actual practice, all the duties of the housekeeper. In turn the pupils do the marketing, attend to the sitting rooms and bedrooms, make the beds and do dairy work in all its branches. They also do all cooking and kitchen and laundry work. The objects aimed at in this system of training are so important to the health and happiness of a home that we are glad to direct attention to it. Those who are interested in the subject can obtain from the Principal, Fryerne, Caterham, any information they desire.

#### THE SANITARY INSPECTORS' ASSOCIATION.

THE address which Mr. John Hutton, chairman of the London County Council, has just given to the Association of Sanitary Inspectors contained a useful lesson to others as well as to those who were present on that occasion. Mr. Hutton entitled his lecture "An Attempt to improve the Sanitary Circumstances of London," and he took the opportunity of explaining the intentions of the Council in the preparation of the by-laws which that body proposes to make under the Public Health (London) Act, 1891. The subject was not only well chosen, but was in every sense timely, for the draft by-laws have just been issued, and Mr. Hutton's explanation will very considerably assist members of sanitary authorities to appreciate their meaning. For our part we regard with much satisfaction this evidence of the interest which the chairman of the great governing body of London takes in the sanitary welfare of the vast population of the metropolis—an interest which augurs well for the development of an efficient administration. Mr. Hutton

referred to the rapid increase of the population of London and sketched the changes which had taken place from the early conditions of the past to those which the County Council were endeavouring to bring into existence under the powers conferred upon it by the Act of last year. He dwelt also on the saving of life which had been effected since medical officers of health were appointed after the passing of the Metropolis Local Management Act of 1855, and showed how the reduction in mortality had particularly occurred in the cases of diseases which were influenced by sanitary measures. Passing then to the proposed by-laws, he pointed out that some of the subjects thus dealt with were referred to in an Act of the time of George III., and these provisions had remained in force until they were superseded by those of the Act of last year. The by-laws relating to house refuse are particularly interesting because they are designed to bring about in the future a daily collection of refuse throughout London, and they at once give to sanitary authorities facilities for organising this system in any parts of their districts in which a daily collection is desirable. The old brick dustbin will eventually be replaced by a movable metal receptacle, all new houses are to be provided with an "ashpit" in this form, and for existing houses every new dustbin is to be of this kind. Whenever the sanitary authority is prepared to make a daily collection of dust it may require the householder, whatever kind of dustbin he has, to provide a movable receptacle, which is to be placed in front of the house at times of which the sanitary authority may give notice. Offensive refuse is to be removed at times and in a manner to prevent nuisance, and the collection of manure in sunk manure pits is to be no longer possible. The by-laws as to water-closets, earth-closets and privies are well designed, and will by degrees effect marked improvement in the apparatus now existing in London. The provisions which may perhaps excite some amount of opposition are those which relate to the disposal of refuse; the Council has evidently made up its mind to rid London of the dustyards where refuse is sorted and dealt with in proximity to inhabited houses, and it will probably be necessary for some sanitary authorities to alter their arrangements to meet the views of the Council. But these changes are distinct gains to London and its inhabitants will be benefited by the more stringent conditions which the Council imposes. It is quite likely that some slight modifications will have to be made in the by-laws before they become law; this is inevitable when any Bill is drafted, but they form a substantial code which will prove in every way serviceable to the metropolis." Mr. Hutton's explanations will go far to make the by-laws acceptable to the authorities who will have to administer them, and we are convinced he has acted wisely in thus introducing them to the body of sanitary inspectors. The interest which the chairman of the Council has manifested in the welfare of the sanitary inspector and in his work will constitute a useful tie between the Council and the large body of men upon whose efficiency the sanitary condition of London must largely depend.

#### THE VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

THE staff and members of this school dined together to the number of over 200, at the Cannon-street Hotel, last Saturday evening. The president, Major Maclure, was in the chair, and was supported by Lord Sandhurst, Under-Secretary of State for War. Major Maclure, in proposing the health of Her Majesty, was able from personal knowledge to say that the Queen was well informed as to their work, and took much interest in it, as also did Miss Nightingale. Lord Sandhurst displayed great interest in the work done by the staff of the school, and in giving the prizes

expressed his intention of being present at inspection on the Monday following. Surgeon-Colonel Hamilton proposed the toast of "Success to the Volunteer Ambulance School of Instruction," and gave a history of the evolution of the whole Volunteer movement. The toast was responded to in an able speech by Surgeon-Captain H. F. Stokes. He said that over a thousand members had received instruction, a high percentage of whom had obtained proficiency certificates. Instructors had been sent on the application of medical officers to distant camps of brigades and regiments, and such localities as Wye, Port Talbot, Bridgend, Minehead and Aldershot. The inspection took place on Monday last at the London Scottish headquarters, when two strong companies paraded in drill order. The examining officers were Surgeon-Captains Yarr and Bostock. Each company was put through a course of stretcher drill and lifting of wounded, after which each man underwent a *vivâ-voce* examination in first-aid, and at its conclusion Surgeon-Captain Yarr announced that he should have much pleasure in recommending the whole of the class for certificates of proficiency. This is the fourth class in succession where all the members have presented themselves for examination and all have passed. The success is attributed to the rule that any man absenting himself from drills or lectures three times is at once struck off the roll, and no man is allowed to present himself for examination unless he knows his work. Such discipline reflects high credit on the medical officer instructors.

#### HÆMOLYSIS.

In the exhaustive and erudite study of the process of blood destruction or hæmolysis, which was chosen by Dr. Wm. Hunter for his recent lectures in connexion with the Grocers' Company Research Scholarship, the proposition that the blood acts in its physiological and pathological relations similarly to other tissues is one which will at the present day be accepted without demur; but, although there is no doubt of the waste and renewal of all tissues and cells, the blood is singularly adapted for observing the method of such changes owing to the special coloured element that it contains. It was then mainly of an exposition of the destiny of hæmoglobin that the lecturer made, and the facts and arguments which he adduced from observation of normal changes on the one hand, and of abnormal—whether induced experimentally or as the result of morbid action—on the other, were both numerous and sufficient. It would hardly be fair to Dr. Hunter to attempt a critical survey of the elaborate details of his work. He was dealing, as he said, with a comparatively novel subject, and no criticism could rightly be passed by anyone who had not traversed the same ground. It may, however, be permitted to indicate a few of the salient points which are to be gathered from his exposition. In the first place, the derivation of bile-pigment from hæmoglobin is unquestioned, and it is to be noted that this conversion is not entirely limited to the liver cells, whither the products of effete red corpuscles are conveyed by leucocytes. For leucocytes and connective tissue cells can also produce pigments identical with bilirubin and biliverdin from hæmoglobin, although in the main the conversion is effected in the liver. The red corpuscles may, however, part with their hæmoglobin under the influence of changes created in the blood plasma, and the colouring matter thus set free may come to be deposited in the spleen, liver and bone marrow. That the portal area of the circulation is the region where this liberation of blood pigment (active hæmolysis) mainly takes place is a view which was, we believe, originally propounded by Dr. Hunter, who has still further elaborated it. He shows that this hæmolysis may occur in health, during digestion, in the spleen and gastro-intestinal capillaries; that it may be effected, in the same area, by the action of toluylendiamine;

and that it probably occurs here in pernicious anæmia and malignant jaundice. The resulting free blood pigment is deposited to a large extent in the liver and to a lesser degree in the spleen, and even in the kidney—as evidenced by micro-chemical examination. The subject embraces, however, many other questions than these which we have indicated; and we only regret that Dr. Hunter had no opportunity to gather up the fruits of his labours in a few general propositions.

#### EPSOM COLLEGE.

ONCE more we have to congratulate the College on receiving a munificent gift in aid of its funds. "J. S.," who recently contributed £1000, has recently transferred to the College long mortgage securities to the extent of £2750. This generous supporter of this most successful and deserving institution has now given between £6000 and £7000 to help on the good work. H. Mayo, a student, has gained an open scholarship of £50 a year at Caius College within the last few days. The College is completely full, and the repute of the school has risen so rapidly that there are already four times as many candidates as there will be probable vacancies at Christmas. Such success and such pressure must compel the council to lose no time in providing extended accommodation.

#### LAPAROTOMY IN ITALY.

PROFESSOR GIUSEPPE RUGGI, who holds the chair of Clinical Surgery in the University of Bologna, performed the other day his fiftieth successful laparotomy, and to celebrate the event, unique (it is said) in the surgical annals of Europe, 120 physicians and surgeons of the city and province entertained him at a banquet in the Hôtel Brun. A medal in commemoration of the event was struck in Professor Ruggi's honour and presented to him in a felicitously eulogistic speech. Professor Ruggi, in acknowledging the testimonial, referred to the high name achieved in abdominal surgery by Bologna, which records on a tablet in her surgical clinique the resection of the liver performed for the first time by Count Pietro Loreta, whose later and no less brilliantly successful feat of digital divulsion of the pyloric and œsophageal orifices affected with fibroid stenosis was described by THE LANCET in its obituary notice of that ill-starred surgeon, whose death by suicide shortly after the operation in question is still mourned in Italy as a national loss.

#### THE HEALTH OF SCHOOL CHILDREN.

AMONG the numerous associations which have recently applied for public assistance in carrying on the work entrusted to them is the committee appointed by the Congress of Hygiene (1891) to inquire into the physical and mental condition of children in relation to their education. The investigations instituted by the committee, as we learn from its latest circular, have not been fruitless. Altogether some 50,000 children attending 106 schools have been examined. These establishments included homes, orphanages, industrial and public elementary schools and those under the control of the Poor-law. The condition of the children as described by the committee is by no means encouraging, though we may gather some hope from the fact that the unhealthy state of many of them did not necessarily imply any marked reduction of the normal standard. Thus, while nearly 6000 presented "bodily defects," 5000 showed "deviations from the normal nerve state," 2000 were pale, thin &c., 3600 were reported as "mentally dull," but only 288 as crippled, deformed or subject to fits. Without a more intimate knowledge of the meaning of such general terms as the above, it is impossible to form a clear idea of the educational capacity of these children. It is sufficiently evident, however, that the physique of a large proportion of them was perceptibly inferior. It is also a

significant fact, as bearing upon questions of hereditary incapacity and of low nutrition as related to such incapacity, that this injurious variation was chiefly noticeable among pauper children and those of criminal parents. The questions whether "overpressure" was not really another name for "underfeeding," and whether the standards of education were equally suitable to all cases, naturally suggested themselves to the committee. Though still without sufficient data to afford a basis for generalisation as to the most appropriate methods of instruction, they are evidently of opinion that some readjustment of the strain thus imposed on weak children is called for. Whether this can best be brought about by varying the amount or quality of the work exacted in any case, or by such arrangements for better nutrition as may appear to be needful, is open to further discussion. A combination of both methods would probably attain the best results. There might also be some advantage in rearranging the hours of work. We cannot but think that if these were more concentrated, so as to leave the better part of the afternoon free from school work, a material gain would be achieved. A reasonable amount of home preparation would then be possible, and this might obviate the fagging drudgery of such preparation carried out late in the afternoon by children whose brains were already wearied by several hours of scholastic labour.

#### THE PLUMBERS' COMPANY.

THAT the importance of plumbing is gradually becoming more and more recognised by the public is a fact which cannot but be highly gratifying. Evidence of this growth in the general estimation of the value of this department of architecture and house building is afforded by the success which has attended the efforts of medical officers of health and the conductors of sanitary associations to promote technical education in this direction. The presence of the distinguished company which on Wednesday last assembled at the dinner given by the Plumbers' Company may be taken as additional testimony, if such were needed, of the great interest taken in technical sanitation. On that occasion the Lord Mayor was supported by about 250 gentlemen, amongst whom were some of the most prominent sanitarians of the three kingdoms. It was fitting that the speech to which chief attention was directed should have been made by the Parliamentary Secretary of the Local Government Board. In it Sir Walter Foster alluded to the Plumbers' Registration Bill, which, after receiving careful consideration in the course of committee, he is hopeful of getting incorporated in the legislative enactments of the coming year. He said that in the department with which he was connected a feeling of great sympathy with the measure existed. Sir Joseph Savory, Mr. Bryant (President of the Royal College of Surgeons) and other gentlemen spoke in appreciation of the useful work of the company, and altogether the festival was of such a kind as to mark a distinct advance in the realm of sanitation to which the energies of the Worshipful Company of Plumbers are devoted.

#### THE ENTHUSIASM OF HEALTH.

SIR JAMES PAGET is desirous of implanting in our national character "an ambition for renown in health" comparable with that for bravery, beauty, or success in athletic games. Let us consider what this means. The subject is one which may be viewed in two different aspects. In the one case health, like the other qualities above mentioned, is regarded as a comparative rarity. As such it must appeal to the sense of admiration in minds of every type, even the most ordinary, and persons of strong physique would then stand out from the half-dead level of pallid humankind like rocks on a sandy shore. This condition we may be sure is very far from

realising Sir James Paget's ambition. His view takes in the subject from another point. It is that of minds higher than the ordinary in respect of their physiological knowledge. He would raise the most ordinary to the level of these and would thus awake in them the slumbering sense of self-preservation in the matter of hygiene. "After virtue, knowledge," said Goethe, thus laying the foundation of his desires in healthy morality, and what virtue was in his ideal of mental satisfaction, health is in the physical system. What were beauty, athletic success, or even bravery—that is, physical courage—without this foundation? We can hardly credit their existence in such a case. A short and perishing life they might have, that is all. Their best and most enduring forms cannot be thus established. The intelligent ambition which appreciates this fact is certainly a feeling to be fostered by every possible means, and we are pleased to think that its culture is in these days increasingly cared for. Hitherto many sins have been committed against the body by persons who knew no better. Thanks to the extension of science teaching these are becoming plainly visible to the eye of reason. What we still want is the development of a yet keener sense than ordinary knowledge, an anxiety to live aright, an enthusiasm to learn and to obey the true law of our nature, moral and physical. We see more of this than formerly. We do not so tamely submit to the cramping tyranny of fashion. We are less easily gulled by the deceit of "wild oats." Even that capricious child, Society, submits many of its habits to sanitary rule. Yet there is room for improvement. The tide of enthusiasm must rise higher.

#### THE SANITARY CONDITION OF HASLEMERE.

THE question of the proper sanitary administration of Haslemere is still the subject of dispute and discussion; it has also become involved in a good deal of confusion by reason of the number of bodies who are concerned and who are intervening in the matter. In the first place the Surrey County Council have urged the provision of a proper system of sewerage and they have recently called attention to the facts that the water-supply is very inadequate and that several polluted wells still remain in use. Then come the rural sanitary authority, who are the properly constituted and responsible health authority for the place, and they, as far as can be judged, are waiting to see how far they will be compelled to go, and with how little complainants of one and another sort will be content. Next come the parochial committee, a body having no functions which can relieve the rural authority of their statutory responsibility, and who seem to differ amongst themselves a good deal as to what ought to be done. And lastly, we read of a Sanitary Aid Committee wishful for reform and of a Ratepayers' Defence Association. The latter body, whilst professing all sorts of interest in the sanitary circumstances of Haslemere, seem principally to attend meetings where changes for the better, but which would cost money, are opposed and, as a rule, voted down. Then, again, we find advocates for and advocates against an adequate water-supply. Some of the latter talk sensibly, and point out that an increase in the supply of clean water means that an increase of dirty water will have to be got rid of, and that such increase will in consequence involve an efficient sewerage to dispose of the extra liquid refuse. This in turn produces a class of opponents who, whilst wishing to avoid sewers with their attendant cost, are yet anxious to do something to stave off the day of a sewer system, and who, if the increase of water did not involve the rapid filling of cesspools and other difficulties, would vote for more water. And in the end we find that Haslemere sanitation is for the present to be met by the purchase of a horse and cart for scavenging, by some drain flushing and by the laying of a few sanitary pipes and such like expedients. But even an extra sanitary

inspector is refused "on the ground of expense." Meanwhile intending residents in this parish will do well to inquire of the County Council what the sanitary history of the place is, what its sanitary circumstances now are and what they are likely to be in the more immediate future.

#### OLD EPSOMIANS' DINNER.

THE sixteenth annual dinner of Old Epsomians was held at the Holborn Restaurant on Tuesday evening, Mr. Henry Morris being in the chair. The treasurer of the College (Dr. Constantine Holman), the head master (the Rev. T. N. Hart-Smith), Mr. J. Lumsden Propert (the son of the founder), Mr. B. Pollard (hon. sec. of the club) and several other members of the Council, and about fifty "old boys," assembled. The speakers referred to the highly satisfactory state of the school and pointed to the number of scholarships gained at the Universities and at the medical schools and to the prospect of having to provide in the immediate future for the accommodation of some 150 more boys. In anticipation of this extension and with the view of avoiding divided services, which the College chapel would then necessitate, attention was drawn to the desirability of either enlarging the present chapel or building a new one. It was resolved therefore to make an effort to raise a fund from Old Epsomians and their friends for rebuilding or enlarging the College chapel. A committee was afterwards formed for carrying this resolution into effect. The probable amount required is £2500 to enlarge and £6000 to rebuild. The meeting, which was a very successful one, was enlivened by instrumental and vocal music rendered by Dr. J. J. Pringle, Mr. Cecil J. Sharp, Mr. Templar Saxe, the Rev. C. C. Elcum and Mr. Harris.

#### THE REPORT OF THE SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

OFFICERS of the law took a prominent part in the discussions of the first autumnal meeting of the Society for the Prevention of Cruelty to Children. The speeches delivered by the Home Secretary and Mr. Lockwood, Q.C., were characterised by much vigour and were in complete accord with the Society's purposes and proceedings. Both were agreed that the sentences imposed in cases of cruelty had erred rather on the side of leniency than of severity. Most persons acquainted with the subject will recognise the justice of this view and also of an argument in which the former speaker insisted on the liability for costs incurred by parents who had by their neglect or other forms of cruelty compelled the State to provide for their offspring. The Massachusetts law goes further than this, and declares for the forfeiture of parental rights on the part of those who may be found guilty of such conduct. A measure of this kind might not be out of place in our own legislation. It is well known that certain magistrates have shown a marked reluctance to deal hardly with criminals of the class in question. This kind of backwardness, as pointed out by the Archbishop of Westminster, is not mercy, and his appeal for more terror in their law cannot fail of approval by the voice of public opinion. We must close these remarks with a brief notice of the Society's present position. A retrospect of the eight years which have elapsed since its beginning shows an increase in the number of cases dealt with from 122 to 9401 and of convictions from 13 to 1104. The present percentage of the latter in relation to cases tried is 94. These are figures which will suffice to prove the need of the Society's efforts. It is to be remembered, moreover, that they concern but a third part of the area of this country, and the fact is also suggestive as regards the condition of children in the other two-thirds, which we may call unprotected territory. This important point was brought out in the speech of the Rev. H. Price Hughes. We regret to learn that the Society, like so many other actively bene-

ficial institutions, has overflowed in usefulness beyond the scope of its bank account. If our memory does not mislead us this is a new feature in its history. The amount of the deficit for the past half-year is stated at £4500. This has not been incurred on behalf of working expenses merely, since these amount to no more than 13½ per cent. of its whole outlay. It is manifest that the cost of legal proceedings and other duties essential to the character of such an Association as this must be as heavy as its success is of public importance. We trust therefore that an appeal for funds which are so well employed will meet with that free and general acceptance to which the Society is entitled.

#### MUSICAL NEIGHBOURS.

It will be generally admitted that the charms of music do now and then fail to be appreciated, and the fact is apt to be somewhat freely attributed to a want of at least one sense in the listeners. If, however, we may judge from the evidence lately tendered in connexion with a suit in the Chancery Division a similar apathy may show itself even among the initiated. There is a freshness about this case which might enliven even a law court. It dealt with the convenience of two adjacent households both addicted to musical performances and, it would appear, equally resentful of each other's privilege in this particular. It is not difficult to picture the condition described as existing. The question arises nevertheless whether in such a case, or more fittingly in any other where the performance is one-sided, no means of relief can be provided. It is evident that while making every allowance for personal liberty, it must be kept within those limits which are essential to collective existence. Comfort in health, safety and progress in sickness, demand that within our own home quiet, if desired, should prevail. Our neighbour may exercise his musical talent if he pleases, but so that any extreme transit of sound to another dwelling is guarded against. Concerts, school singing, practising and the like must exist on mutual sufferance. The dividing wall buttressed with furniture or otherwise may aid materially in securing the needful seclusion. Still it must be remembered that this is, after all, common property and may not be used at the caprice of either of its joint owners as a mere sound-receiving diaphragm. This view of the matter may possibly require modification to suit, if this be possible, the extravagances of disputants in music. It can hardly fail to commend itself as of general utility, more especially where, as in many of the newest houses, the common partition is of the slightest character.

#### STAS'S SCIENTIFIC WORK.

THE Fellows of the Chemical Society attended a special meeting at Burlington House last Tuesday for the purpose of doing honour to the memory of Stas and signifying the general admiration of British chemists for his well-known scientific work. A lengthy paper entitled "Jean Servais Stas and the Measurement of the Relative Masses of the Atoms of the Chemical Elements" was prepared by Professor J. W. Mallet and read before the Fellows by Professor H. E. Armstrong. In spite of its great length the paper was listened to with rapt attention throughout. All those present knew they were listening to the biography of a great master who would be ever remembered "not merely for his contributions to descriptive chemistry in the discovery and examination of new substances, or for his eminence as a teacher or writer, or for his practical application of knowledge to the affairs of human life—though in all these directions his services claim honourable record in the history of chemical science—but especially will those who themselves cultivate this science ever think of him as the man who with untiring zeal and clear-sighted power of investigation worked on for years upon the foundation stones of

quantitative chemistry, thinking no pains too great, no toil too severe that could render more accurate the results which others might take and trust as the basis of their researches, however little the greater part of mankind might feel interest in or even know of his quietly pursued investigations." An interesting discussion followed the reading of the paper, in which Professor Crookes, Dr. Russell, Professor Dewar, Professor Muir, Dr. Scott and others took part. They were unanimous in expressing their high admiration and appreciation of the splendid and brilliant researches of Stas, and urged upon the younger chemists present to take up the theme, to follow in his steps and with that earnestness with which Stas was so preëminently endowed to seek as diligently as he did after the truth.

#### EPIDEMICS IN MEXICO.

YELLOW FEVER is widely prevalent in Mexico. From Cordova comes intelligence that the disease has been fatal to about a thousand persons, business being suspended and many of the inhabitants having fled to the neighbouring mountains. Enteric fever and small-pox are also announced as prevailing somewhat widely in different parts of the country.

#### THE POLLUTION OF THE EXE.

WE understand that the condition of the River Exe has been recently the subject of inquiry. The river, it is stated, is polluted by sewage from Tiverton and from villages between that point and Exeter, and it is alleged that the Culme in addition to sewage receives the refuse of numerous paper mills as well as of tanneries and creosote works. The Exeter Town Council has appointed a committee to consider and report on plans for dealing with the sewage; these have been prepared by the city surveyor and it is to be hoped that no time will be lost in providing means for the purification of the river, for the conditions described are anything but a credit to the county.

#### CHARGES AGAINST HOSPITALS.

WE have had to comment only too frequently on the attitude assumed by certain of our lay contemporaries towards the hospitals. To insert in their columns accusations against a hospital founded on the inaccurate statements made at an inquest or the verdict of a jury which has either been misled by those statements or improperly directed by the coroner may be a very good way of increasing the sale of a paper, but does no credit to the paper which does it. The reputation of a hospital is dear to those who are in any way interested in its management or prosperity, and its funds do not permit of action such as might be taken by a private individual in a case of libel; the generous and manly thing would be to defend the helpless. The attack in most instances appears to be made without due care, for the charges could on inquiry at the institution maligned be easily refuted. Most certainly any charges could and ought to be investigated at the time and not allowed by the presiding coroner to go forth from his court with his approval as true unless proved. No hospital or charitable institution should be judged without an opportunity of clearing itself, and the frequency with which these charges are made in a particular district—charges which we have often carefully investigated and found groundless—compels us to reluctantly conclude that there is a desire on the part of some or other persons to damage the reputation of a hospital. If there is neglect of duty on the part of the hospital by all means let it be brought to light, and if censure is deserved let it be given. Such things should be made known, but before condemnation it is usually the custom in England at least, for the accused to be told of the charge and asked what can be said in his favour to refute it, not to condemn him in his

absence and even without his knowledge of the charge. "Audi alteram partem" is still a good motto, and worth remembering.

#### PREVALENCE OF MEASLES.

MEASLES is becoming somewhat epidemic in certain parts of the United Kingdom. In Hull no less than 600 cases with forty-six deaths were recorded last month and in Glasgow 300 attacks were announced at the close of last week.

#### THE INSTITUTE OF CERTIFICATED INSPECTORS.

A NEW association has been formed, consisting of sanitary inspectors who have obtained a certificate from the Sanitary Institute or some other body. The principal objects of the institute are stated to be: (1) the raising of the status of certificated sanitary inspectors; (2) the advancement of sanitary science; (3) the dissemination of sanitary knowledge among its members and the general public; (4) the rendering of practical assistance and encouragement to those holding appointments as sanitary inspectors but who have not yet obtained the qualifications necessary to become members or associates. These objects are altogether praiseworthy, and we hope that the institute may be able to do useful work in the directions indicated. We are, however, not quite sure that the ground is not already covered by the work of the original Sanitary Inspectors' Association, which has now been in existence some years. An element of weakness is, we think, introduced through the division of the sanitary inspectors into two bodies, and it does not appear to us that the mere possession of the certificate forms a sufficient reason for this separation, or to lead to much expectation that the new body will be able to take any very active part in the promotion of the second of its objects. We are in favour of sanitary inspectors being fully educated to perform the duties which are imposed upon them by Acts of Parliament and the Orders of the Local Government Board made thereunder, and it may be that a justifiable rivalry between the two associations will stimulate their members to fit themselves better for the public service.

#### PUERPERAL THROMBOSIS OF THE PULMONARY ARTERY.

DR. LUSK says "thrombosis of the veins furnishes the most frequent cause of sudden death in labour and during the puerperal period." A very graphic case of the sort, though happily ending in recovery, is reported by Dr. W. W. Hewlett in the *New York Medical Record* of Nov. 29th. A patient, after a very easy labour, contrary to the advice of Dr. Hewlett, sat up on the fourth day, as she always had done. On the twelfth day, when everything seemed favourable, and while in the sitting posture, she was seized suddenly with intense dyspnoea, extreme restlessness, followed by cold extremities, cyanosis, nausea and profound weakness. The respirations were 58, the pulse 130, the temperature normal. There was no hæmorrhage; at times the respirations were 80. She was calling for air, had profuse perspiration, cold extremities and livid nails. There was no pain; the intellect was perfectly clear. No heart sound was audible in front. She could not be auscultated behind. Her only complaints were shortness of breath and extreme cold. The treatment consisted in absolute rest, drawing the urine off by a catheter, keeping the extremities warm, free stimulation with whisky and ammonia and the use of digitalis. For a week the patient suffered from faintness, dyspnoea and cold sensations. After the eighth day improvement began, but was very gradual. She was not able to sit in her chair till three weeks after the attack. There can be little doubt as to the nature

of the lesion in this case, and quite as little as to the value of the therapeutic measures which were so intelligently used. Such cases are happily rare, but most practitioners of experience have seen them. The wonder is, considering the complicated nature of the puerperal condition, that they are not more frequent.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Berlin.*—Dr. Ludwig Katz has been recognised as *privat-docent* in Otology.

*Copenhagen.*—Dr. Hirschsprung has been appointed Lecturer in Children's Diseases.

*Dorpat.*—Dr. Vasileff has been appointed Professor of Special Pathology and Therapeutics in succession to Dr. Unverricht.

*Munich.*—Dr. Gustav Klein of Würzburg has been recognised as *privat-docent* in Midwifery and Gynæcology.

A GREAT many humane persons will feel a sense of relief in learning, on the authority of the *Yorkshire Herald*, that the wretched woman who has so frequently figured in police reports under the name of "Tottie Fay" and a multiplicity of aristocratic aliases, has been found to be insane and is recommended to be removed to a lunatic asylum. The constant repetition of her name in the police reports led many people to believe that she was suffering from mental disease and was irresponsible for her conduct. She was probably at best an emotional creature of weak mind and unstable nervous system, and the intemperate habits to which she became a victim did the rest.

At the Conference of Port Medical Officers of Health to be held to-day (Saturday) at the Mansion House the following subjects will be brought under discussion: Medical inspection, quarantine, addresses of destination, disinfection &c., disposal of infected corpses, disposal of other infected articles not capable of disinfection, hospitals, other difficulties experienced or anticipated and other matters. The Lord Mayor will preside. The Conference will be opened at 11 A.M., and the first sitting will be continued until 1 P.M. The second sitting will begin at 2.30 P.M. The advantage of such an interchange of views amongst port medical officers is very obvious.

ITALY is actively preparing for the International Congress of Medicine and Surgery to be held in Rome in the last week of September, 1893. Throughout the peninsula the medical schools are constituting local committees for their adequate representation at that "parliament of the profession," the last announcement to this effect having come to us from Pisa, where Professor Pasquale Landi has been elected president, Professor Gaetano Rummo vice-president, and Dr. Gustavo Gasperini secretary, of a very strong "comitato" consisting of fourteen prominent physicians and surgeons belonging to that school.

DR. WALTER HAYLE WALSHÉ died on the morning of the 14th inst. at his residence, 41, Hyde Park-square, after a long and painful illness. His works on diseases of the heart and on diseases of the lungs are classical treatises, and place him in the foremost rank among the fathers of English modern medicine. His remains will, in conformity with his written directions, be cremated next Saturday at Woking.

THE late Hon. W. H. Cross, M.P., whose lamented death has been announced this week, was junior counsel for the Royal British Nurses' Association in their application for the charter, along with Sir Horace Davey and Mr. Muir Mackenzie. Mr. Cross attended the first hearing, but was too ill to attend the second. He took more than a mere professional interest in the case.

DR. E. C. PERRY has been appointed by the Court of Committees to succeed the late Dr. J. C. Steele as Superintendent of Guy's Hospital. Dr. Perry vacates the appointments of Warden of the College and Dean, but continues to hold the posts of assistant physician to the hospital and demonstrator of morbid anatomy in the medical school.

THE town council of Weybridge has adopted a new scheme for the disposal of its sewage, which includes the discharge of the clarified effluent into the Thames at a point above the intakes of the London water companies. The scheme is understood to have the approval of the Local Government Board.

At a meeting on the 12th inst. of the managers of the Royal Infirmary of Edinburgh, Surgeon-Major-General S. A. Lithgow was appointed to the office of superintendent of the infirmary. He is at present serving as principal medical officer of the Southern District on the staff of the Duke of Connaught.

THE next meeting of the Epidemiological Society of London will be held at 11, Chandos-street, Cavendish-square, on Dec. 21st, at 8 P.M. A paper on "Measles Epidemics, Major and Minor," will be read by Mr. B. A. Whitelegge, M.D., B.Sc.

DR. PAUL RAYMOND has been awarded a prize, offered by the President of the French Republic, for the best essay on the means to be adopted by the Legislature or by private initiative for restricting the abuse of alcohol and combating its dangers.

MR. THOMAS HAWKSLEY, M.D., M.R.C.P. Lond., founder of the National School of Handicrafts for Destitute Boys at Chertsey at a cost of £30,000, and formerly in practice in London, died at Chertsey on the 13th inst. at the age of seventy.

A BENEVOLENT lady, Mrs. Brown, who died at Adelaide recently, left £100,000 to the Home for Crippled Children and to the Convalescent Home for the Infant Poor.

THE death is announced of Dr. James Hobson Aveling, of Upper Wimpole-street, on the 13th inst.

## THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE twentieth annual general meeting of the constituents of the Metropolitan Hospital Sunday Fund was held at the Mansion House on Tuesday, Dec. 13th, when the Right Hon. Stuart Knill, Lord Mayor (president and treasurer), occupied the chair. The LORD MAYOR was supported on the platform by Sir Sydney Waterlow, Dr. Adler, the Rev. Prebendary Daniel Moore, Mr. F. C. Carr-Gomme, the Rev. J. F. Kitto, Dr. C. J. Hare, Dr. Kennedy, the Rev. W. H. Barlow and others. In opening the proceedings he said it gave him very great pleasure to follow the example of his predecessors in giving the use of the Mansion House for the purpose of the meetings in connection with the Hospital Sunday Fund. To him the Fund was a source of great pleasure indeed, and he would be glad to help it in every possible way.

SIR SYDNEY WATERLOW, in moving the adoption of the report, said that this was the twentieth time that he had had the gratification of submitting this resolution to the constituents. In commenting upon the report he drew attention to the resolution which was passed at the meeting of the Council on Nov. 25th last, when it was decided to recommend to the Committee of Distribution that all accounts presented under law 4 of the Constitution on or from Jan. 1st, 1893, should be audited by a chartered accountant and said

that it would now read as "certified by either a public or a chartered accountant." This change he thought would bring the accounts into one form and they would have a much easier task when comparing the relative merits of the respective hospitals. He pointed out that the contributions received this year were less because they had not had a repetition of a donation of £5000 which had been received last year. With regard to the provision of surgical appliances they were now granted to persons who could show that they were really in need of them, and they did all they could to prevent poor people from tramping a number of miles for the purpose of obtaining letters.

The Chief Rabbi (Dr. ADLER) seconded the resolution, remarking that it would be desirable to see an increase of hospital accommodation in the outlying districts of London.

A resolution recommending that the laws of the Constitution in force last year be continued being passed, the Rev. J. F. KITTO proposed that the Council for the year 1892 be re-elected for the year 1893, with the following names to fill vacancies—viz.: Rev. John Storrs, B.D., Rev. J. Monro Gibson, D.D., Rev. Donald McLeod, D.D., Rev. W. H. Harwood, Admiral the Hon. F. Egerton, Sir George B. Bruce, Thomas Bryant, Esq. (President, Royal College of Surgeons), Walter H. Burns, Esq., Thomas Rannie Grant, Esq., J. H. Hale, Esq., and Howard Potter, Esq.

Dr. C. J. HARE, in seconding this resolution, remarked on the representative way in which the selection had been made, embodying as it did men of all ranks, creeds and professions.

The Rev. C. J. RIDGWAY then proposed the following resolution: "That the 11th of June be fixed for Hospital Sunday of 1893 and that the cordial coöperation of all ministers of religion within the metropolitan area be again invited in the usual way."

The Rev. W. H. BARLOW seconded, testifying to the benefit of the addresses given at the Mansion House previously to Hospital Sunday, which he said had been reported in THE LANCET, and those ministers who were wise made it the foundation of their addresses on the following Sunday.

The LORD MAYOR, in answer to a question in reference to district meetings, said that they had been tried, but they became very flat, and, either accidentally or otherwise, it so happened that the funds were larger when there were no district meetings than when there were district meetings. With regard to the meeting at the Mansion House before Hospital Sunday, he should follow the example of those who had gone before him, and he hoped with the same success.

A vote of thanks to the Lord Mayor terminated the meeting.

## CHOLERA.

### CURRENT NOTES, COMMENTS AND CRITICISM.

CHOLERA still prevails in Brittany, notably at Lorient. The disease has also appeared at Vannes. Further north two cases and one death at the civil hospital of Dunkirk, three cases and two deaths at Hesdin, and two deaths at Equihen, near Arras, are recorded. A woman also died of cholera at Dizy-Majenta, near Epemay. In fact, there are strong grounds for fearing that in the north-west of France the disease is the reverse of extinguished. There was one case at Hamburg on the 8th inst., the patient having arrived from Stettin on the Baltic, and two cases previously on Nov. 9th and 11th, and it is now reported that four cases have occurred since the 12th inst. Russia has been the greatest sufferer from the cholera epidemic and the disease, although it has greatly abated, still continues to prevail in a large number of the affected provinces. Of 51 formerly affected 15 only are now completely free. In the province of Podolia there were 864 victims during the past week:—In Kieff, 508; in Bessarabia, 498; in Tamboff, 297; in Kherson, 205; in Volhynia, 70; in Saratoff, 50; and in the Province of Samara, 35. A certain number of cases are also still reported weekly from twenty-nine other provinces. The last issued official statistics form a terrible record. There have been altogether since the outbreak of the cholera epidemic 550,000 cases in the whole of Russia, of which 260,000 proved fatal. From Berlin we learn that Dr. Klemperer, assistant to Professor Heydon, had read a paper before the

Society of Surgeons of the Charité Hôpital upon the results obtained from an injection of milk from cholera-infected goats. It is clear that a much larger amount of information is required, and of a far more precise character than that which has appeared in the daily papers, before any opinion can be arrived at in regard to such experimental researches.

With regard to the paper read by Surgeon-Colonel Hamilton on Cholera, its Epidemic, Progression and Causation, and the debate that followed, we may here make a few remarks. The paper covered a wide field, but one of its main contentions was as to the adequacy of the so-called water theory to account for the spread of epidemic cholera. According to the published abstract, it would appear—for the point does not seem to have been brought out with perfect perspicuity—that while the great importance of a pure water-supply in times of cholera is fully recognised, it was contended that an impure water-supply was not invariably the sole agent at work or the only vehicle, by any means, by which the cholera-cause was spread; and, on the other hand, that even in the cases where impure water was admittedly a powerful factor, if not the primary and essential one, its acquired potency in this respect had not been demonstrably traced to the introduction and presence of any specific cause, contagium or vitalised agent—such as the comma bacillus, for example. In any discussion it is necessary to understand where the point of divergence takes place. We may assume that all are agreed that a pure water-supply protected from all sources of contamination is obviously of great importance, for this is now commonly regarded as an accepted axiom in hygiene and beyond controversy. No one acquainted with India would probably deny that the unwholesome water-supplies of that country are great causes of disease there. The fact that the drinking-water of the larger number of Indian stations is obtained from wells which are always liable to contamination, and that in a large number of instances there is chemical proof that the well water is bad and unfit for use, places the fact beyond dispute. As far as the public health of India is concerned there is no direction probably in which more good could be effected than in this. So far then as the provision of pure water goes as a public health measure all are practically agreed; but it is at this point that the divergence of opinion begins, for those who hold that cholera depends entirely and exclusively upon the presence of a specific agent in the water supplied to a population take up a very precise and definite doctrine which they are bound to follow out to a logical conclusion. Of course if cholera depends upon a micro-organism which multiplies in the bodies of its subjects, moisture, food and clothing may also be vehicles for the spread of infection as well as water, but it is generally held that the water supplied to a population offers the greatest facilities for its spread and is consequently regarded as the most common vehicle for its dissemination. That all epidemics and outbreaks of cholera in India and elsewhere are to be accounted for, however, by a contaminated water-supply is believed by many to be far too exclusive a view and opposed to facts and experience, of which Surgeon-Colonel Hamilton cited some examples by way of samples. In the subsequent debate Dr. Simpson of Calcutta, in criticising the paper, made, as might have been expected, some very pertinent remarks. He attributed the conflicting views in regard to cholera which obtained in India and Europe to the different methods of investigation adopted. He rightly laid stress upon a thorough and systematic method of investigation into the causes of an outbreak being undertaken at once and on the spot whilst all the facts are still fresh and can be ascertained and examined. Statistical investigations should follow, and occupy a secondary, and not a primary, place. Dr. Simpson appears to hold that importation, contaminated water and bad drainage are the principal factors in the spread of cholera. It is obviously impossible in the course of an evening to discuss adequately so large, difficult, and complex a subject as that of cholera. Much that might have been said was necessarily omitted, and even statements of fact are susceptible of being differently read and interpreted. It must be borne in mind that the period of introduction and that of the manifestation of the disease need not coincide. The effects of the distribution of the cholera-cause may be immediate or remote, according to whether the conditions prevailing at the time be favourable or otherwise. Let it suffice for the present to say that the views entertained by many Indian observers are not generally accepted in this country and on the Continent. Suspension of judgment is an attitude with which people have generally little sympathy, but we must never-

theless be content in the meantime to await the results of public researches before we can dogmatically insist upon any theory or hypothesis yet put forward as being exclusively the right one.

## CHOLERA IN BELGIUM.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Brussels Bureau d'Hygiène and the Epidemic.—Official Statistics of Cholera in Belgium.—Cholera in the Province of Antwerp.—Cholera in the Brussels Suburbs.—Influence of Season and Locality on Cholera.*

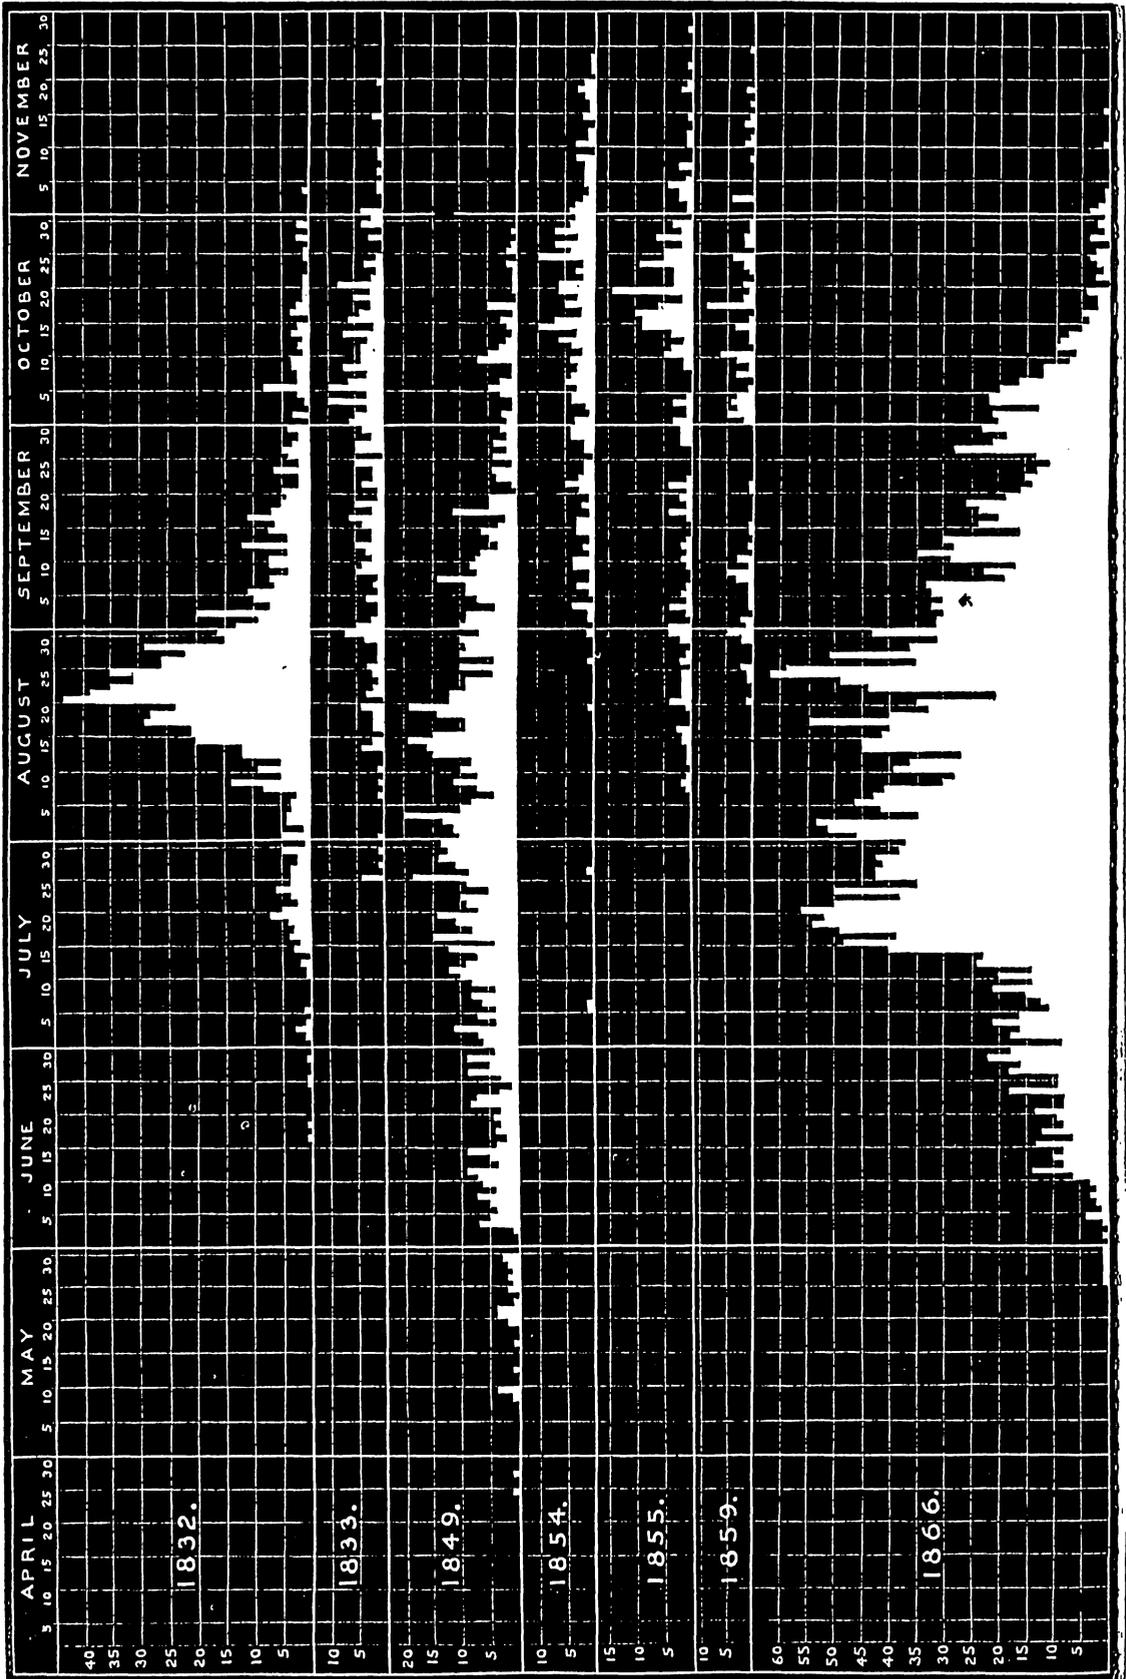

THE efficacy of good sanitation as the most reliable means of preventing cholera is being put to a severe test at Brussels. The capital of Belgium can boast of being one of the best administered towns on the Continent of Europe so far as 'sanitation' is concerned. In THE LANCET of Nov. 16th, 1889, I gave some account of the improvements which had been effected. Taking the vital statistics by periods of five years I showed that the average death-rate from 1868 to 1873 was 29.3 per 1000 per annum and the zymotic death-rate 4.90 per 1000. The Bureau d'Hygiène was created in 1874 and great sanitary works were undertaken, with the result that from 1884 to 1887 the death-rate had fallen to 22.9 per 1000 and the zymotic death-rate to 1.31. During the following five years the improvement has been still further accentuated. This year, for instance, when in August the first cholera scare spread to the town of Brussels, the death-rate was only 20 per 1000, and I described at the time the elaborate precautions that were taken to ward off the danger. The few cases of cholera which occurred in August and September were nearly all, if not all, what might be described as imported cases. The patients were either travellers from Paris or else the crews on board barges that had come from Antwerp &c. Since the creation of the Sanitary Bureau in 1874 from 11,000 to 12,000 houses have been overhauled, altered and improved in respect of drainage &c. As the town of Brussels consists of only about 18,000 houses hopes were entertained that though many cases of cholera might come from the outside, still the epidemic would not gain a footing in the capital. The principal danger was with the floating population that constantly arrived in Brussels by the canals from Antwerp, Boom and other towns where cholera prevailed. For instance, when I was in Brussels last a barge arrived from Antwerp with its skipper, named De Tay, very ill on board. The barge was stopped for medical examination before being permitted to unload in the port of Brussels. The bargeman's wife, unaccustomed to these proceedings, was seized with panic; she imagined that the authorities were going to accuse her of seeking to poison her husband. Thereupon she seized all his clothes—the clothes stained with cholera dejections—and threw them into the canal. When Dr. Huart and Dr. Matthys, the doctors entrusted with the sanitary work for that district, arrived on the spot they found that the bargeman was suffering from cholera. Thereupon the alarm increased. No one could be induced to remove the man from the barge, so that the doctors had to take him in their arms, hoist him up the ladder of the little cabin as best they could, carry him along the quay till they reached their carriage, in which the bargeman was conveyed to the hospital. Then men had to be engaged to recover the clothes from the canal and burn them; but the burning was of little use, for the soiled clothes had been some hours in the water. Notwithstanding this and similar incidents cholera did not seem to spread in Brussels. Yet Brussels has suffered from several cholera epidemics, the last being the most severe. Indeed it was this last epidemic which decided the authorities to spare no pains to improve the sanitary state of the town. For this work Brussels had the good fortune to secure the services of Dr. E. Janssens, who was appointed chief of the Bureau d'Hygiène when this institution was first created and has continued ever since to organise the sanitary services of the town. With a view to meeting the present danger of cholera Dr. Janssens has recapitulated the history of the previous epidemics, and more especially of the great epidemic of 1866. In the Bureau d'Hygiène there is, suspended from the wall, a huge map of Brussels such as it was in 1866, and every house where cholera occurred is painted red. Any inhabitant of Brussels can see this map and thus at a glance realise

what happened in his house and his district during the last epidemic. Many of the worst houses fortunately have been demolished; but careful note has been taken of those that remain and instructions have been given to the police to keep special watch to see that cholera does not break out again in the same houses. These precautions have not been taken in vain, for, though Brussels has so far escaped from what may be called an epidemic, still there have been some cases, especially during the last few weeks, of cholera in that town. In all thirty-one cases of cholera have been recorded at Brussels. Of these, twenty-eight were inhabitants; the other three were strangers to the town. There are three patients still under treatment; twelve recovered and sixteen died. Several of these cases of cholera occurred, as was foreseen, in the same houses where there had been cholera in 1866. It was also found that, in spite of all the efforts of the sanitary authorities, well water was still consumed in some of the houses where these cases have occurred. Consequently it has been necessary to employ coercive measures to close the wells and to substitute the town supply of water.

Unfortunately from a sanitary point of view Brussels is but the centre of a vast agglomeration of separate communes, each enjoying a wide measure of autonomy or local self-government. These surrounding communes are only separated by the width of a street from Brussels. They are not suburbs, but in some portion of their area form the actual continuation of the town. Whatever may be the administrative and political divisions, there is no topographical division. These numerous communes, at least so far as sanitation is concerned, are not so well administered as the town of Brussels. Enjoying more space and, being nearer the purer air of the country, they ought, with equally good sanitation, to be in a safer position than Brussels itself. The reverse is the case; and it is these suburbs, rather than Brussels itself, which have suffered from cholera. To the north-west, at Molenbeek St. Jean, there have been 62 cases of cholera, and the gravity of these cases may be judged by the fact that there were 52 deaths. At Anderlecht, to the south-west, there were 16 deaths from cholera; in the south, at St. Gilles, 2 deaths and in the north-east, at Schaerbeek, 1 death from cholera. No cases of cholera have been reported from the other surrounding communes—namely, Laeken, Etterbeek, St. Jossetenoode and Ixelles. From this it will be seen that there is much more danger of cholera in the suburbs than in the town, and that Brussels has been hedged in and surrounded on all sides by cholera cases. It speaks well for the sanitation of Brussels that so far the town should have escaped with but 31 cases and 16 deaths.

Also it must be borne in mind that travelling is cheap and easy in Belgium and that travellers are continually going backwards and forwards from cholera-infected towns and districts to the capital. Dr. Bus, the Director-General of Hygiene, has just communicated to the Belgium Superior Council of Public Hygiene full statistics of this year's epidemic of cholera in Belgium. From this official report it appears that from the 20th of July to the 12th of October there were noted 1207 cases of cholera and 626 deaths from this cause. From the 13th of October to the 4th of November there were 129 cases and 63 deaths. From the 5th to the 23rd of November there were 105 cases and 51 deaths. This gives a grand total, counting from the 20th of July to the 23rd of November, of 1441 cases and 740 deaths. With regard to the present distribution of the epidemic, it is still from the province of Antwerp that the greatest number of cases are reported. Here, in the town of Boom, there have been during the last fortnight 12 cases and 5 deaths. Cholera has prevailed in this town ever since August 26th. In THE LANCET of Sept. 17th I described at length the wretched sanitary condition of this unhappy locality, which I visited with Dr. Desquin, the President of the Provincial Medical Commission. During the fortnight, from the 5th to the 23rd of November, cholera has been most prevalent at Malines; there were 26 cases and 12 deaths. The other towns in the province of Antwerp were—Niel, 7 cases, 1 death; Isighem, 3 cases, 1 death; Terhaighen, 4 cases, 2 deaths; Bergerhout, a suburb of Antwerp, 2 cases, 1 death; Bumpst, 3 cases, 3 deaths; and Duffet, 2 cases, 1 death. Altogether, for the province of Antwerp since the 5th to the 23rd of November, 59 cases and 26 deaths. During the same fortnight there have been in the Province of Western Flanders, at Bruges, 20 cases and 13 deaths; at Westkirke, 1 case, 1 death; at Oudenbourg, 1 case, 1 death; at Assebroeck, 2 cases. Altogether for this Province, 24 cases and 15 deaths. In the Province of Brabant

DIAGRAM OF SEVEN CHOLERA EPIDEMICS AT BRUSSELS.

1832.	Population 99,414; Mortality from Cholera 864 = 87 per 10,000	1854.	Population 147,690; Mortality from Cholera 281 = 19 per 10,000
1833.	" 100,214; " 268 = 27 "	1855.	" 149,000; " 236 = 16 "
1849.	" 198,189; " 1607 = 78 "	1859.	" 157,260; " 114 = 7 "
	" 1866; Population 168,494; Mortality from Cholera 849 = 212 per 10,000		

at Brussels, 9 cases and 4 deaths; in the Province of Western Flanders, at Steendorpe, 2 cases and 1 death; at Termonde, 5 cases and 2 deaths; and at Lokren, 2 cases; in all, 9 cases and 4 deaths. In the Province of Liège, in the town of Lidje, 3 cases and 2 deaths. There is no cholera in the Provinces of Limbourg, Luxembourg and Namur. Such, then, is the present state of affairs; and though the epidemic is evidently decreasing, still it is spread over such a multitude of districts that it is impossible not to fear a virulent return of the scourge.

At the same time it must be noted that, of the seven epidemics of cholera which have occurred in Brussels, only those of 1832 and 1833 and of 1854 and 1855 followed one upon the other. Dr. Janssens has prepared and just issued a most interesting diagram of these seven epidemics which he has kindly given us permission to reproduce in the columns of THE LANCET. Unfortunately the limits of space render it impossible to do full justice to this work. The original diagram is divided into as many vertical columns as there are days of the year, while every horizontal line measures one death. In the reproduction it has been necessary to leave out the winter months, and the horizontal line is drawn at every five deaths. Nevertheless, single deaths can be readily seen and counted. What it has not been possible to show is the significant fact that, though the influence of season on the epidemics is very emphatic, the note of warning is often sounded altogether out of season. Thus, in 1849, there was one death on the 21st of February, then no further deaths were noted till the 24th and the 27th of April, on which days the second and third deaths took place. Again, in 1854, there was one death on the 7th, 14th, 15th and 17th of January, two deaths on the 21st, one death on the 28th, and one death on the 3rd, the 5th and 10th of February. Then nothing whatsoever happened till the month of July; when, as it will be seen by the accompanying diagram, there were three deaths, and also three deaths in the month of August. During the next three months there was a very small epidemic, which did not quite die out till January of the ensuing year. In this latter month (January, 1855) there were 18 deaths, occurring from the first day of the year to the 18th. Then no more cholera was reported before the following month of August, when a very small epidemic broke out, which reached its maximum intensity in October. These two epidemics of 1854 and 1855, which were preceded by a few cases in the depth of winter, only caused 282 and 236 deaths respectively, and this is equal to 19 and 16 deaths per 10,000 inhabitants. The smallest epidemic of all was that of 1859, when there were but 114 deaths, or 7 deaths in 10,000 inhabitants. The epidemic of 1849, which was preceded by a few warning cases, was more serious, as there were 1007 deaths, and this gives a proportion of 73 deaths per 10,000 inhabitants. The most serious were the first and the last epidemics—that of 1832, with 864 deaths, or 87 per 10,000; and that of 1866, with 3469 or 212 deaths per 10,000 inhabitants. The epidemic of 1833 caused but 268 deaths, or 27 deaths per 10,000 inhabitants. For the three severest epidemics, those of 1832, 1849 and 1866, the month of August was the most fatal; during the four slight epidemics of 1833, 1854, 1855 and 1859, the greatest number of deaths occurred in October; but all the seven epidemics are chiefly fatal within the four months July to October. The effect of the season of the year on the disease is thus most emphatically denoted.

The influence of locality on cholera is set forth with equal emphasis by Dr. Janssens, by statistics in which he gives for every street, court or alley in Brussels the number of deaths from cholera which occurred during the seven epidemics; then, calculating the number of inhabitants in these streets, he adds the proportion per cent. of deaths. Thus, in looking over this list, I find that during the seven epidemics there were 39 deaths from cholera in the Rue de Flandre, and these were only equal to 1 per cent. of the population of that street. In the Rue aux Laines there were 25 deaths, or 1.2 per cent. Then, going to the other extreme, in the Impasse St. Médard, a small court, there were 7 deaths, and this is the highest record, for it is equivalent to 20.8 per cent. of the population, or a little more than 1 death out of every five persons living in the court. The next worst is the Impasse Wellotiens with 11 deaths, or 18.6 per cent.; then follow the Impasse Peeters, 41 deaths, or 17.3 per cent.; the Impasse Tordier with 23 deaths, or 17.2 per cent.; the Impasse du Templier with 2 deaths, or 16.6 per cent.; the Impasse du Charon and Rue

Ophen, each with 15.7 per cent. of deaths to the population, and so on down to the 1 per cent. mentioned above.

There are still unfortunately some black-spots remaining in Brussels. Good sanitation does not altogether obliterate the effects of poverty, and though a town may be greatly improved as a whole, there still remain dark corners where no amount of supervision can prevent overcrowding and dirt. The cholera seems already to have found out one or two of these evil places; but as yet little harm has been done. If it is humanly possible, with the knowledge and the means actually available to prevent the mischief extending, past experience shows that the population of Brussels may rely on the devotion and ability of its sanitary authorities and of their distinguished chief, Dr. Janssens.

## THE MUNICIPAL SLAUGHTER-HOUSE OF BRUSSELS.

(FROM OUR SPECIAL CORRESPONDENT.)

IN Brussels all private slaughter-houses have been rigorously abolished. A large public slaughter-house was built so far back as the year 1836, and there is a law bearing the date of March 30th, 1836, and another that of Aug. 12th, 1848, which regulate the management of this slaughter-house. Public slaughter-houses organised by municipalities, controlled by municipal functionaries and belonging to the municipality have existed in Belgium for half a century, and yet in London, the greatest metropolis in the world, there is no such organisation. The innumerable private slaughter-houses of the British metropolis are not only a dangerous nuisance in themselves, but how is it possible to control the quality of the meat coming from such places? The inspectors cannot be everywhere at one and the same time, and though they have the right of entry and of inspection, it is practically impossible to watch constantly so many slaughter-houses scattered over so vast a tract of ground. In London all private slaughter-houses should be abolished and a few large model public slaughter-houses substituted in different districts. At these large slaughter-houses an efficient staff of veterinary surgeons, bacteriologists and public functionaries could be kept on the spot, and every animal and every carcase could be thoroughly examined by properly trained and qualified veterinary surgeons. Then and then only can we feel certain that no unwholesome meat is sent to the market.

To the municipal slaughter-house at Brussels has been annexed the municipal cattle market. It stands to reason that wherever it is possible the cattle market and the slaughter-house should be close to each other. On the exterior boulevard of Brussels there are handsome iron sheds with glass roofs, where the cattle are brought and exposed for sale. One day it is the market for horned cattle, the next day for sheep, the day after for swine, and so on. If the cattle, as is generally the case, are bought for slaughter, on quitting the market they have only to pass through a gateway to enter the slaughter-house. In the slaughter-house there are vast stables, where the cattle can be kept for a day or two, if necessary, before they are slaughtered. The cattle market is practically in the open air, though under shelter. It is built of iron and glass and paved with granite, all non-absorbing substances, which can be easily washed and purified. The weighing-machine, made of iron, is carefully washed with a disinfectant after each market. The fee paid for bringing cattle to this market is 5*d.* for horned cattle, 2*d.* for calves and pigs, and 1*d.* for sheep. The butcher having made his purchases conveys his animals to the slaughter-house and then pays for its use 2*s.* 5*d.* per head for big cattle, 1*s.* 8*d.* for cows or horses, 10*d.* for a pig or a calf, and 2*d.* for a sheep. The stables in the slaughter-house are lofty buildings with windows on each side. There is nothing special to be said about them—they are neither better nor worse than thousands of other stables. Nor is there much to be said concerning the slaughter-sheds, which are of about the same size and build, though of course the interior fittings are different. The pavement is of large blue granite flagstones, which are slightly chipped so that the surface is roughened and thus the men and beasts are prevented from slipping. At the spot selected for slaughtering there is an especially large stone to which is affixed an iron ring. A rope passing through this ring pulls the bullock's head

downwards, when it is struck with a mallet. It requires about twenty minutes to skin and draw the animal, to sling it up, and push it along the beams, to which it is suspended by the hind legs, and hung out of the way at the other side of the slaughter-shed.

There now comes into play an important regulation. The heads, feet, liver, lights &c., have to be boiled on the spot, and there is an establishment set apart for tripe dealers in the slaughter-house. Thus those portions of the carcass which cannot be easily kept are boiled then and there, and are therefore in a much safer condition to be sent to the various retailers in the town. In another and distinct part of the slaughter-house the entrails are treated—washed, the skins scoured and the tripe set aside. Here also the blood, collected in shallow tin pans, is exposed to the action of the air and the albumen secured for various industrial purposes. This section of the Brussels slaughter-house is certainly very defective. The work is done in what looks like a railway arch—a vaulted structure with very inefficient ventilation. The pavement is uneven and the foul splashing from the washing of the entrails can easily sink into the earth and contaminate the subsoil. The ventilation is altogether inefficient and the stench at times very objectionable. Of course, there are thousands of flies about, and their bites have occasionally, though fortunately not frequently, been known to be very venomous. This portion of the slaughter-house does no credit to the Brussels municipality, and all that can be said is that it was built long before the attainment of the present knowledge of hygiene. It was therefore very satisfactory to turn from this unpleasant spectacle and visit the section devoted to the stabling and the slaughtering of pigs. This is admirably ventilated and beautifully clean. The central portion of the pointed roof overlaps the lower portion, so that the air can pass freely in and out between these two portions of the roof, and thus there is continuous ventilation the whole length of the ceiling.

From time to time various regulations have been issued for the management of this slaughter-house. The latest bears the date of December 10th, 1891, and is signed by the Burgomaster, M. Buls. These rules maintain the necessity of forbidding the entrance into the town of any meat that does not bear the stamp certifying it has been duly examined. All persons who carry meat through the town must also carry with them a written statement giving the name of the owner of the meat and the address of the place whither it is about to be conveyed. All meat must be taken directly to its destination, any loitering on the road is illegal. All hotel keepers, restaurant keepers, or persons who have boarders staying with them, must, if they bring meat into Brussels, observe the same rules with regard to the examination of the meat, the stamp it bears, its rapid and direct transport through the streets; in fact, must submit themselves to the same laws and regulations as govern the butcher's trade.

Nevertheless, and this is a strange and inexplicable inconsistency, a person may introduce meat into the town for his own use without submitting to any control further than that of giving his name and address. Thus a person may go outside Brussels, buy some meat, and so long as he declares that it is for his own private consumption no measures are taken to see that the meat is wholesome. Of course it will be said that a control exists in the outlying district where such meat is purchased. But supposing the meat is not purchased in the regular way,—it may have been obtained from some farmer who has secretly slaughtered an animal because he was doubtful as to its state of health,—such dangerous, unwholesome meat can be introduced into Brussels under the pretext that it is only for private consumption. This private consumption includes a dinner given to friends at which all the friends can be poisoned. But if in such a case the host were to call upon his guests to pay for the dinner he had given them, he would then be considered as a boarding-house keeper, or restaurant keeper, and would be prosecuted if his meat had not been examined and stamped. Thus a citizen of Brussels may feed himself and his friends on bad meat so long as he does it gratuitously. This, I take it, is a gross exaggeration of the respect due to individual liberty. If persons can be punished for attempting to commit suicide, why should they not be punished for eating bad meat, or meat that has not been properly examined?

Two other services attached to the Brussels municipal slaughter-house are of interest. Here are kept under surveillance the calves that have been employed to supply the vaccine lymph. These calves, having served their purpose, are brought for slaughter, but before and after death they are

very carefully examined by the veterinary surgeons. It is only when a favourable report has been received that the lymph taken from the calves is given out for vaccination purposes. In another part of the slaughter-house there is the dépôt for stray dogs. Here they are kept in strong iron cages, and here also is the fatal lethal chamber. It is a simple apparatus. On the asphalt flooring an indentation has been made. This is about three inches deep and two inches wide and forms a square. In the centre is placed the cage containing the dog. By a pulley arrangement an iron box is let down over the cage. It is like a square bell covering over the cage, and fits exactly into the indentation or little trench made in the flooring. The trench is filled with water, so as to prevent the gases escaping, and ordinary coal gas is discharged inside the cage. In this manner the dog soon dies of asphyxia.

Though the abolition of private slaughter-houses and the creation of a municipal slaughter-house offer the best guarantees for the due inspection of meat, it must be confessed that the municipal slaughter-house of Brussels is now in grave difficulties. Formerly it was a source of income to the municipality, now its sheds are to a great extent abandoned, and it is difficult to defray the working expenses. This is due to an unexpected but a most energetic and successful competitor. A private company, having at command a very large capital, has purchased extensive grounds in the commune of Anderlicht. This is not Brussels, but it is just outside Brussels. Here they have built a gigantic cattle market and slaughter-houses, which are much better situated than the Brussels slaughter-house, for they are in the open, almost in the country, and by the side of both a railway line and a canal. The cattle step out of the railway trucks into the cattle market, instead of being driven along the streets. The general conveniences are therefore much greater. But the buildings are not only modern, they have many new and scientific improvements. To begin with, the water-supply is most ample and of good quality. An artesian well has been sunk to a depth of 100 metres. Above the well there is a water tower 35 metres high, and on its summit the water reservoir has a capacity of 150 cubic metres. An engine raises water into this reservoir at the rate of 500 litres per minute, and at present the consumption of water in the slaughter-houses and cattle market is about 150 cubic metres per day. A cheap and practically unlimited water supply should be one of the first considerations that should govern the selecting of a site for a slaughter-house.

Then there must be a prompt and cheap means of disposing of manure and all offensive refuse. This is supplied at Anderlicht by barges on the canal, which pass all along one side of the slaughter-house and cattle market. The manure these barges take away is sold at the market for from 2s. 10 $\frac{1}{2}$ . to 3s. 8 $\frac{1}{2}$ . according to the season of the year. As the stable will hold 900 head of cattle there is naturally a considerable accumulation of manure, and the stabling that now exists is found to be insufficient. It is proposed to spend £40,000 more to extend the buildings. These stables are most carefully built. There are no angles, the mangers are carefully rounded off so that no dirt can accumulate in corners and all can be very easily cleaned. Along the whole length and slightly above the manger is a water pipe, so that it may be instantaneously flushed out. The flooring is of Kilker Dutch brick, which is very hard, and is placed in full cement, so that the flooring becomes absolutely watertight. For the older built stables the more luxurious flag-stone pavement was used, but this is not so good, though dearer, because it is not watertight. The roofs are rounded and ten metres in width. Other roofs are of tin, with inner stycco ceiling, which can be and is washed with the fire hose. There are louvre windows on each side, and at the two ends are ventilators on the Venetian blind system.

The slaughter-house sheds are more elaborately ventilated than the cattle sheds. The doors are in part of wire-work, so that even when shut the air comes through. On the roof there are special oowl ventilators. The windows are face to face on both sides of the sheds, and to supplement these will be found numerous openings on a level with the floor. In the part of the building devoted to the preparation of tripe &c. the apex of the roof is open along its whole length, and this opening cannot be closed. In some of the sheds the Otto Meurer patented flooring has been tried. This is a sort of compressed cement which does not get polished or slippery. It is formed into blocks slightly convex, perhaps a foot broad. On either side is a very small circular drain or gutter which is bridged over by a perforated iron plate. The whole

of the flooring slightly inclines and all liquids are carried off instantly. One bucket of water thrown over these convex blocks will do more effective cleansing than several buckets on an ordinary floor.

Some interesting experiments are being made here in the destruction of bad or diseased meat. To sterilise such carcasses by exposing them to steam only arrests temporarily the decomposition, and carcasses thus treated might contaminate the fields where they are thrown as manure. The chemist at Anderlicht prefers to use sulphuric acid. The gases that arise from the dissolution of the carcass are made to pass through a coke fire, so as to be purified and prevent nuisance. When the carcass is completely dissolved by the acid this liquid, which retains practically all the nitrogenous matter of the animal in the form of ammonia, is thrown on phosphates at about 20 per cent. It is calculated that 500 kilos of dissolved animal carcass and sulphuric acid make with the phosphates 1000 kilos, or one ton of excellent manure, which can be sold for about £2 8s., and should not cost more, all told, than £1 15s. to produce. From the public health point of view it is most important that an advantageous method of dealing with condemned meat or carcasses should be discovered. There will then be less temptation to smuggle away such condemned meat and convert it into sausages &c.

Altogether there is no denying the great superiority in position, size, buildings and appliances of the slaughter-houses and cattle market built by a private company at Anderlicht. These are much superior to the municipal slaughter-house at Brussels. The result is that most of the trade has gone to Anderlicht, which is quite near enough to Brussels to supply all the wants of the capital. Indeed, Anderlicht is a suburb of Brussels which happens to be under a different municipal authority. The company hope to increase the number of inhabitants at Anderlicht because of the business that the market will bring, then they will be able to sell at a profit the land they bought before building the market and slaughter-houses. It is, in fact, a gigantic speculation which has altogether overthrown the calculations of the Brussels municipality, and should serve as a warning to reformers in England. Municipalities must be careful when they undertake to build slaughter-houses to see that under some rival and neighbouring local authority other slaughter-houses are not brought into existence which shall disastrously compete with them. The experience of the Brussels municipality is perhaps unique, and it is impossible not to sympathise with that body. They gave all Europe an excellent example so far back as the year 1836 when they built their municipal slaughter-house. Of course Brussels was but a small town then, and the site selected was as much outside Brussels then as Anderlicht is to-day. The newer portions of the Brussels slaughter-house are better built; but, of course, so old an institution cannot be expected to have all the modern improvements, and it compares unfavourably with the Anderlicht slaughter-house. And now, through want of a common understanding between the local authorities of Anderlicht and of Brussels, a war is waging in respect to slaughter-houses which has resulted in a very serious loss to the Brussels taxpayers and in no gain in the reduction of local taxation at Anderlicht.

## A WELSH MEDICAL SCHOOL.

THE University College of South Wales and Monmouthshire at Cardiff is a flourishing and progressive institution, and having done excellent work in the past is now desirous of extending its influence, and in this wish is supported by all the ardour of a strong local patriotism. So far as university education in medicine is concerned the University of South Wales has hitherto taught only the preliminary arts and sciences. It has taken as its ideal in this teaching the standards of the University of London, and the successes of its pupils at that University have been well above the average. The students have evidently been thoroughly and efficiently instructed in the subjects and syllabuses that have been put forward by this University as a guide for its examinations, and university education on these lines has been most systematically and vigorously carried on to the great advantage of its numerous students from Cardiff and from the adjacent area of South Wales. For many years past the University authorities have been anxious to develop

a medical side, and donations to about £5000 have been promised to its support. The finance committee presented a detailed report to the Council on the 7th inst., and it was not only determined to institute the proposed School of Medicine, but to advertise at once for professors of anatomy and physiology, each at a stipend of £350 per annum. We presume that some large share of the students' fees is to be added to such a remuneration. The medical school is evidently intended to fulfil two very different objects. It is to carry out the curriculum of the Intermediate M.B. Examination of the University of London, and this doubtless will be well done. There are many reasons why the scientific portion of a medical student's education should be taught in the country, provided that good teachers, plenty of material and efficient apparatus can be found. The second part of the scheme does not so well satisfy us. The earlier subjects of the curriculum for the non-university student can be learnt in the dissecting-room and in the laboratory, side by side with his fellow who is preparing for the University, but the attempt to add clinical work and hospital practice, if they are to be at all thorough, is a much more doubtful procedure, and in laying down the opinion that students should attend a hospital from the first, the Council is not in accord with those who have drawn up the new regulations of the examining boards or with most university authorities. If whilst he is spending two or three years at Cardiff the student is only to learn bandaging and dressing and the rudiments of surgery and medicine we have nothing to urge against it, but if anything more ambitious in the way of clinical instruction and hospital work be attempted it will end in failure. Science may be well taught in University Colleges in many provincial towns; efficient clinical teaching and practical work with sufficient material for the future practitioner's thorough training can only be obtained in the largest teaching-centres and in our most populous cities.

## PROPRIETARY MEDICINES.

ON Wednesday morning last, Mr. Piper, grocer, of 20, Warwick-road, Pithlico, and others represented by counsel, appeared before his Honour Judge Bateman, at the instance of the Pharmaceutical Society, for an alleged breach of the Pharmacy Act, 1893. The action was brought to recover the penalty for selling a proprietary medicine, known as Dr. Collis Browne's chlorodyne, said to contain a preparation of opium, a poison scheduled in the Act.

The plaintiffs were represented by Mr. Grey, and Mr. Bonsor appeared for the defendants.

Mr. Bonsor said that he admitted the sale and purchase of the preparation, but not that it was a poison within the meaning of the Act. It was true that it had been decided that they were subject to a penalty for not labelling the preparation, but the preparations which his clients sold were not poisons within the meaning of the Act.

His Honour: Is it not curious that these questions should again be raised before me after it has been decided by a police magistrate, who is a judge of first instance like myself?

Mr. Bonsor: The patent medicine question has never been gone into before a magistrate.

His Honour: Surely it has and discussion after discussion has ensued. Mr. Bonsor: But no evidence has been called on behalf of the defendants to show what a patent medicine is or is not.

His Honour: Everybody knows what a patent medicine is.

Mr. Bonsor: I think not.

His Honour: Surely it is a medicine produced by letters patent.

Evidence was given proving the purchase of the bottle and that it contained two grains of morphine to the ounce.
